published by the American Institute of Physics

Soviet Physics—Technical Physics Vol. 19, No. 1, July 1974

(Russian original: Zh. Tekh. Fiz., Vol. 44, No. 1, pp. 1-240, January 1974)

THEORETICAL AND MATHEMATICAL PHYSICS

1 (3) Focusing of an astigmatic beam by a doublet and a symmetric triplet of quadrupole lenses . . . . V. I. Chetvertkov
3 (6) Round metal-optical waveguide filled with a two-layer dielectric . . . . V. A. Pruzhanovskii

PLASMA

9 (16) Excitation of Alfvén waves in decay instabilities . . . . A. G. Elfimov, F. M. Nekrasov
12 (22) Emission of waves from a plasma layer . . . . T. A. Davydova, A. A. Zhmudskii
16 (28) Stabilization of MHD instabilities by a high-frequency current in a straight system. . . . . V. P. Fedyakova
20 (34) Nonmonoenergetic relativistic electron beam in a bounded collisional plasma . . . . V. P. Grigor'ev, N. S. Shulaev
22 (38) Second-harmonic generation and emission in wave conversion at a plasma boundary. . . . . A. N. Kondratenko, V. G. Shaptala, V. M. Kuklin
25 (43) Conversion of an electromagnetic wave into an ion-acoustic wave in an inhomogeneous plasma . . . . A. N. Kondratenko, V. M. Kuklin
28 (48) Nonlinear plasma waves and ion-acoustic waves in an isotropic plasma . . . . V. Sh. Livadonov, S. M. Fainshtein
31 (53) Ionization discontinuity in large-amplitude striations . . . . A. V. Nedospasov, V. G. Petrov
35 (59) Experimental investigation of anode processes in a closed electron-drift accelerator . . . . I. V. Melikov
38 (65) Dynamics and emission of coaxial plasma shells in air . . . A. F. Aleksandrov, V. V. Perebeinos, A. T. Savichev, I. B. Timofeev
43 (73) Recombination in an expanding plasma . . . . Yu. A. Bykovskii, N. N. Degtyarenko, V. F. Elesin, V. E. Kondrashov, E. E. Lovetskii, A. N. Polyanichev, V. S. Fetisov
49 (83) Spatial characteristics and loss of plasma produced by an electron beam in a magnetic trap . . . . M. Yu. Bredikhin, A. I. Maslov, A. I. Skibenko, E. I. Skibenko, I. P. Fomin, V. B. Yuferov
53 (91) Microwave discharge in argon . . . . E. V. Belousov, A. S. Bryukhovetskii, A. V. Prokopov
57 (98) Electron energy distribution and electrical characteristics of the positive column in H_2 and $H_2 + Cl_2$ . . . . V. V. Zaitsev, A. I. Maksimov, V. I. Svettsov
60 (102) Effect of electron—atom collisions on electron motion in a gas diode . . . . V. I. Babanin, A. Ya. Énder
66 (113) Diagnostics of a laser-produced plasma by a scattering method using an electron-optical image converter . . . . . E. A. Burunov, G. M. Malyshev, G. T. Razdobarin, V. V. Semenov

ACCELERATORS

70 (119) Proton extraction from the 70-GeV accelerator for the Ludmila liquid-hydrogen chamber (extraction system S) . A. A. Aseev, A. I. Drozhdin, B. A. Zelenov, É. A. Merker, L. L. Moizhes, K. P. Myznikov, A. A. Roshchin, V. M. Tatarenko, M. A. Kholodenko, A. D. Artemov, L. N. Vaulin, V. I. Gordin, I. I. Kovalevskii, V. N. Rozhkov, M. M. Suvorov, A. S. Sudarushkin, V. I. Chuiko

HOLOGRAPHY

77 (131) Imaging properties of traveling intensity waves in the recording of dynamic three-dimensional holograms . . . . Yu. N. Denisyuk

PHYSICAL ELECTRONICS

81 (138) Extrapolation of the Langmuir S-curve to cesium pressures of 10-100 torr . . . . V. E. Dubinskii, S. Ya. Lebedev
84 (142) Effect of crystal structure on certain angular dependences of the ion—electron-emission yield . . . . B. A. Brusilovskii, V. A. Molchanov
88 (148) Perveance of a vacuum with a point cathode . . . . S. P. Bugaev, E. A. Litvinov, V. V. Lopatin, G. A. Mesyats

91 (153) Production of collimated beams of high-energy electrons . . . . V. I. Nemchenko

GENERAL

98 (164) Nonradiative electron transitions and thermal effects in laser-irradiated transparent dielectrics . . . . B. I. Makshantsev, A. A. Kovalev, R. K. Leonov, P. A. Yampol'skii
103 (173) Dielectric properties of foamed ceramics at millimeter wavelengths . . . . N. A. Irisova, G. V. Kozlov, V. E. Mandrusov, B. S. Cherepanov, I. M. Chernyshev
105 (177) Two-spin oscillator with optical orientation of electrons and nuclei . . . . R. A. Zhitnikov, V. V. Semenov
110 (185) Dynamic magnetic-resonance phenomena . . . . P. S. Kuts, V. S. Mel'nik

BRIEF COMMUNICATIONS

115 (193) Longitudinal oscillations in an ultrarelativistic electron plasma . . . . D. I. Dzhavakhishvili
116 (194) Contribution of multiphoton processes to the linear dielectric constant . . . . V. A. Bushuev, R. N. Kuz'min
117 (196) Effect of cathode emission on the threshold for striations . . . . N. A. Vorob'eva, Yu. M. Kagan, V. M. Milenin, A. Kh. Muradov
119 (197) Ionization oscillations in a plasma in the presence of ionizing radiation . . . . B. V. Vainer
121 (199) Plasma confinement in a time-increasing multipole magnetic field . . . . V. G. Padalka, N. S. Repalov
123 (201) Reflecting properties of an inhomogeneous anisotropic plasma layer . . . . V. A. Zhivulin, G. I. Makarov
124 (202) Current limiting by self magnetic field in a plasma accelerator . . . . A. G. Korsun
127 (206) Parametric plasma instabilities excited by the sudden application of an electric field . . . . A. B. Kitsenko, K. N. Stepanov
129 (208) Electron repulsion in a time-resolving electron-optical image converter . . . . M. M. Butslov, M. E. Gertsenshtein
131 (210) Aberrations in a straight ion-optical accelerator . . . . E. I. Gerasimov, A. I. Solnyshkov, G. V. Tarvid
134 (213) Effect of electron reflection on the voltage–current characteristics of a high-voltage, hollow-cathode, glow discharge . . . . Ya. Ya. Udris, V. A. Chernov, L. G. Guseva
136 (215) High-power nanosecond electron accelerator with inductive storage . . . . B. M. Koval'chuk, Yu. A. Kotov, G. A. Mesyats
138 (217) Ionization of a gas-discharge gap by fast electrons . . . . O. B. Evdokimov, A. P. Yalovets
140 (219) Ionization and recombination coefficients in a discharge excited by fast electrons . . . . Yu. I. Bychkov, Yu. D. Korolev, A. P. Khuzeev
142 (221) Peak current in a cold-cathode magnetron . . . . I. M. Vigdorchik, V. P. Timofeev
144 (224) Effect of selenium and sulfur on the work function of tungsten . . . . N. V. Volkov, Yu. K. Gus'kov, Z. N. Kononova, Yu. I. Kostikov
146 (225) Displacement of ion-current retardation curves in surface ionization in a strong field . . . . N. I. Ionov
148 (228) Investigation of the work function of a tungsten cathode after bombardment by inert-gas ions . . . . P. N. Chistyakov, R. A. Milovanova, V. V. Lytkin
150 (230) Switching characteristics of a discharge in water . . . . V. M. Kuleshov, S. L. Nedoseev, V. P. Smirnov, A. M. Spektor
152 (232) Reversibility of chalcogeneide materials in holography . . . S. B. Gurevich, N. N. Il'yashenko, B. T. Kolomiets, V. M. Lyubin, M. V. Sukharev
154 (234) Magnetoacoustic transducer based on the domain structure of a ferromagnetic material . . . . G. L. Gurevich, G. A. Vul'gal'ter
156 ERRATA

Soviet Physics – Technical Physics Vol. 19, No. 2, August 1974
(Russian Original: Zh. Tekh. Fiz., Vol. 44, No. 2, pp. 241-480, February 1974)

THEORETICAL AND MATHEMATICAL PHYSICS

157 (241) Calculation of permittivity of an inhomogeneous dielectric by a variational method . . . . . G. A. Ermakov, A. G. Fokin, T. D. Shermergor
161 (249) Calculation of bounds for the effective permittivity of an inhomogeneous dielectric . . . . . G. A. Ermakov, A. G. Fokin, T. D. Shermergor
166 (257) Resonance properties of a pulsating dielectric sphere . . . . . A. G. Nerukh, N. A. Khizhnyak
169 (263) Potential factors for an inhomogeneous ellipsoid . . . . . M. L. Levin, R. Z. Muratov
171 (267) Generation of Bernstein modes in a beam–plasma system . . . . . V. N. Fedorenko

PLASMA

175 (273) Excitation of electromagnetic ion cyclotron waves by fast ions . . . . . T. D. Kaladze, D. G. Lominadze, K. N. Stepanov
177 (277) Parametric instability of an electron beam in a magnetic field . . . . . A. I. Pasynok, N. S. Repalov
181 (284) Scattering by ion-acoustic waves in a rectangular waveguide . . . . . S. V. Troitskii
185 (291) Multimode parametric interactions in a plasma with low-frequency pumping . . . . . Yu. M. Sorokin, N. S. Stepanov
190 (300) Kinetic theory for wave reflection from a moving plasma . . . . . Yu. V. Bogomolov
193 (305) Scattering of high-frequency electromagnetic waves by ion-acoustic oscillations in a bounded plasma . . . . . V. G. Shaptala
197 (311) Electric field and plasma structure near a large charged body . . . . . L. A. Malyavin, A. M. Moskalenko
201 (318) Production of an ion beam by a magnetic system with opposed fields . . . . . V. B. Glasko, A. G. Sveshnikov, N. N. Semashko
206 (325) Structure of a perturbation near a highly charged body in a weakly ionized plasma . . . . . L. A. Malyavin, A. M. Moskalenko
211 (333) Electron energy distribution in the afterglow. I . . . . . A. B. Blagoev, Yu. M. Kagan, N. B. Kolokolov, R. I. Lyagushchenko
215 (339) Electron energy distribution in the afterflow. II . . . . . A. B. Blagoev, Yu. M. Kagan, N. B. Kolokolov, R. I. Lyagushchenko
220 (348) Radiation energy of a magnetoplasma compressor . . . . . V. I. Berkov, A. I. Morozov
224 (355) Physical properties of an electrodeless pulsed discharge in a gas-filled glass cell . . . . . Yu. I. Chutov, N. S. Baranchuk, M. R. Lozovich, V. G. Danilov
229 (364) Narrow-band decimeter radiation from lightning . . . . . E. L. Kosarev, Yu. G. Serezhkin

GENERAL

234 (372) Properties of underexpanded and overexpanded supersonic gas jets . . . . . A. V. Antsupov
239 (380) Gas-kinetic removal of neutral molecules from an ion beam . . . . . V. P. Ivanov
243 (387) Electron-microscope and x-ray study of thermionic emitters made from Mo–Pt alloys . . . . . B. B. Shishkin, R. S. Bakhtiyarov
251 (400) Analysis of the cathode spot in a vacuum arc . . . . . I. I. Beilis
257 (411) Emission processes at the cathode of an electric arc . . . . . I. I. Beilis
261 (419) Time dependence of ion currents produced through surface ionization. Ionization of Ba on the (111) face of iridium . . . . . É. Ya. Zandberg, E. V. Rut'kov, A. Ya. Tontegode
264 (424) Efficient ion source . . . . . D. Kh. Abdrashitova, V. G. Babaev, M. B. Guseva
267 (429) Measurement of statistical parameters of scattering particles in laminar flow by Doppler spectroscopy . . . . . A. P. Ivanov, A. Ya. Khairullina, A. P. Chaikovskii
271 (435) Condensation of a dense vapor flow . . . . . V. G. Dneprovskii, B. A. Osadin, N. V. Rusakov
275 (442) Effect of focusing conditions on the morphology of surface films produced with a laser . . . . . V. G. Dneprovskii, B. A. Osadin
278 (447) Thermophoresis and diffusophoresis of small, volatile aerosol particles . . . . . Yu. I. Yalamov, E. R. Shchukin

280 (451) Electron spectrometer for electric excitation of nuclei in a storage ring . . . . D. M. Nikolenko, S. G. Popov
284 (457) Strobe unit for measuring luminescence in the range 10^{-7}–$2 \cdot 10^{-10}$ sec . . . . V. A. Bonch-Bruevich, N. A. Tolstoi
287 (463) Optical characteristics of K-8 glass subject to radiation from a neodymium laser . . . . A. M. Bonch-Bruevich, Ya. A. Imas, V. S. Salyadinov, A. V. Shatilov

BRIEF COMMUNICATIONS

290 (468) Electron energy distribution in a high-frequency discharge in an axial magnetic field. . . . . S. D. Vagner, V. A. Virolainen, Yu. M. Kagan, T. A. Kalmykova
292 (470) Line shape of a quadrupole mass spectrometer . . . . G. I. Slobodenyuk
294 (472) Investigating prebreakdown fields in water by means of the Kerr effect. . . . . I. T. Ovchinnikov, K. V. Yanshin, É. V. Yanshin
296 (474) New method for obtaining probe characteristics. . . . . Yu. I. Osipov
299 (477) Condensation of an erosion plasma . . . . B. A. Osadin, N. V. Rusakov

Soviet Physics – Technical Physics Vol. 19, No. 3, September 1974

(Russian original: Zh. Tekh. Fiz., Vol. 44, No. 3, pp. 481-688 March 1974)

THEORETICAL AND MATHEMATICAL PHYSICS

301 (481) Energy resolution of quadrupole lenses for charge-particle beams . . . . V. S. Siksin
308 (491) Radiating discharges confined by walls . . . . A. F. Aleksandrov, I. S. Marshak, A. A. Rukhadze
315 (502) Nonlinear statistical theory of a condensate of plasmons. II. Stochastic heating of plasma ions by large-scale Langmuir turbulence . . . . F. Kh. Khakimov

PLASMA

319 (508) Surface waves in a magnetized plasma in a radio-frequency field . . . . E. E. Lovetskii, A. N. Starodub
323 (514) Magnetic field in a θ pinch with an axial conductor. . . . . . . Ya. F. Volkov, V. G. Dyatlov, N. I. Mitina
326 (519) Damping of ion-acoustic waves in a bounded plasma . . . . . A. N. Kondratenko, V. M. Kuklin,
329 (525) Forces in a Hall plasma accelerator . . . . O. N. Mironov
335 (536) Theory of the positive column in neon . . . . Yu. B. Golubovskii, Yu. M. Kagan, R. I. Lyagushchenko
340 (544) Similitude in Hall-current plasma accelerators. . . . . A. I. Morozov, I. V. Melikov
343 (549) Equilibrium flow in a Hall-current plasma accelerator. . . I. V. Melikov
347 (556) Focusing of a neutralized ion beam by a plasma-optics system. . . . . I. I. Demidenko, N. S. Lomino, A. I. Morozov, V. G. Padalka
351 (564) Fast electrons and x rays from nanosecond gas discharges at 0.1-760 torr. . . . . L. V. Tarasova, L. N. Khudyakova, T. V. Loiko, V. A. Tsukerman
354 (569) Electron energy distribution in helium, nitrogen, and their mixtures. . . . . K. D. Asvadurov, I. A. Vasil'eva, V. M. Torchinskii

QUANTUM ELECTRONICS

358 (575) Use of plasma accelerator for optical pumping of lasers. . N. P. Kozlov, Yu. S. Protasov
361 (580) Efficiency of light-beam conversion by dynamic three-dimensional phase holograms . . . . D. I. Stasel'ko, V. G. Sidorovich

ACCELERATORS

366 (588) Beam focusing in an accelerator with inductive energy storage . . . . V. A. Glukhikh, O. A. Gusev, E. G. Komar, V. S. Kuznetsov, M. P. Svin'in, R. P. Fidel'skaya
368 (591) High-current pulsed electron accelerator with an annular beam . . . . M. I. Avramenko, V. A. Glukhikh, O. A. Gusev, E. G. Komar, O. L. Komarov, V. S. Kuznetsov, A. S. Perlin, M. P. Svin'in

PHYSICAL ELECTRONICS

371 (596) Stability of field-emission beams in nanosecond discharges . . . . L. P. Babich
373 (599) Optimum dimensions of a coaxial thermionic converter . . V. V. Sinyavskii
378 (606) End current in a magnetron with a secondary-emission cathode . . . . G. G. Sominskii, S. A. Fridrikhov, O. Yu. Tsybin, A. P. Karizhskii
382 (612) Excitation collisions between magnesium ions and inert gas atoms. . . . . V. L. Ovchinnikov, O. B. Shpenik, I. P. Zapesochnyi
385 (617) Surface-ionization determination of the electron affinities of silver and gold . . . . E. Ya. Zandberg, A. G. Kamenev, V. I. Paleev
390 (625) Effect of ion microfields on emission of an arc cathode . . A. M. Dorodnov, V. B. Davydov, A. V. Kozyrev, Ya. A. Pomelov
394 (632) Simulation of ion scattering on diatomic molecules . . . . . M. L. Aleksandrov, N. S. Pliss, A. P. Shcherbakov

GENERAL

396 (635) Rate for evaporation of a liquid into vacuum . . . . A. P. Andreev, M. A. Gurevich

402 (644) Multiple reflection of light in a shock tube . . . . V. D. Mironov, V. I. Selyakov

BRIEF COMMUNICATIONS

405 (649) Nonlinear instability of a helicon packet in an anisotropic plasma. . . . . Ya. N. Istomin, V. I. Karpman
407 (651) Optimization of the paraxial asymptotic electric field in electron-optical systems. . . . . V. E. Ginzburg, V. N. Danilov
410 (655) Long-wave cyclotron instability in a plasma in an inhomogeneous magnetic field . . . . A. S. Kukushkin
412 (658) Transmission of a high-current relativistic beam through a gas . . . . Yu. V. Tkach, I. I. Magda, G. V. Skachek, S. S. Pushkarev, I. P. Panchenko
414 (660) Radar sounding of sea ice . . . . V. V. Bogorodskii, V. P. Tripol'nikov
416 (662) Two-section solenoid with internal "equally-loaded" section; power as a function of the length of the internal section . . . . G. S. Veisig, A. P. Doroshenko, P. P. Rybin
419 (666) Optical radiation from nanosecond discharges in dense gases. . . . . L. P. Babich
421 (668) Plasma density in a magnetoplasma compressor. . . . . . . A. K. Vinogradova, V. P. Vinogradov, A. I. Morozov, A. A. Sergeev
424 (671) Investigation of spatial distributions in a laser-produced plasma by Hα absorption. . . . . G. V. Ostrovskaya, N. A. Pobedonostseva
427 (674) Two-omegatron study of the pumping characteristics of an NÉM-300 magnetic-discharge pump for a mixture of gases . . . . M. K. Bulgakov, V. G. Rogozinskii
429 (677) Possible use of the schlieren method to measure characteristics of turbulence. V. G. Ivanov
432 (680) Titanium-pump system for hydrogen. . . . . K. G. Mirzoev, V. G. Rogozinskii, V. L. Ushkov
434 (682) Temperature dependence of trace diffusion coefficients of certain gases. . . . . A. É. Loiko, B. A. Ivakin, P. E. Suetin

Soviet Physics — Technical Physics Vol. 19, No. 4, October 1974

(Russian original: Zh. Tekh. Fiz., Vol. 44, No. 4, pp. 689-896, April 1974)

THEORETICAL AND MATHEMATICAL PHYSICS

435 (689) Charged-particle motion in a dipole magnetic field ..... L. G. Glikman

PLASMA

441 (698) Excitation of acoustic waves by ion-acoustic turbulence .. Kh. O. Abdulloev, F. Kh. Khakimov, V V. G. Makhan'kov
446 (706) Plasma acceleration in crossed electric and magnetic fields ..... V. I. Aref'ev
455 (723) Conversion of regular charge-density waves in an inhomogeneous plasma ..... S. S. Kalmykova, A. P. Tolstoluzhskii
459 (729) Role of collisions in plasma absorption of electromagnetic waves near the lower hybrid ..... B. V. Galaktionov, V. V. D'yachenko, M. M. Larionov, O. N. Shcherbinin
463 (735) Distributed systems for feedback control of a tokamak plasma ..... V. F. Gubarev, Yu. I. Samoilenko
468 (743) Plasma diffusion in the Tornado device ..... A. N. Kozyrev, B. P. Peregud
475 (754) Electron density in an argon afterglow ..... O. P. Bochkova, R. I. Lyagushchenko, É. A. Sukiasyan, Yu. A. Tolmachev
478 (759) Supersonic plasma jet from a high-power pulsed discharge ..... M. A. Sultanov
483 (766) Experimental investigation of microwave radiation produced by hypersonic flows ..... V. A. Lyutomskii, V. M. Polyakov, V. G. Testov

QUANTUM ELECTRONICS

486 (770) Parasitic amplitude modulation of a stabilized Nd^{3+}:YAG laser ..... N. N. Galaktionova, A. A. Mak, A. P. Khyuppenen
491 (778) Thermal effect of continuous laser radiation on optically transparent media ..... N. S. Bardina, A. I. Portnyagin, M. Yu. Sklyarov, A. A. Churin
495 (784) Quenching in the CF$_3$I photodissociation laser ..... G. A. Skorobogatov, V. M. Tret'yak, V. S. Komarov
499 (791) Energy input in electrical ionization lasers ..... Yu. I. Bychkov, Yu. D. Korolev, Yu. A. Kurbatov, G. A. Mesyats
503 (797) Pulsed neodymium-glass laser with periodic Q switching ..... T. A. Kuzovkova, E. V. Nilov, V. A. Rusov, I. N. Semenov, A. A. Chertkov
506 (803) Characteristics of the electrical ionization CO$_2$ laser ..... Yu. I. Bychkov, Yu. A. Kurbatov, V. V. Savin

ACCELERATORS

509 (808) Linear accelerator for beam injection into a slowly rising magnetic field ..... D. G. Borisov, A. I. Gryzlov, V. M. Levin, A. V. Ryabtsov

GENERAL

511 (812) Use of the distribution function to describe free molecular beams ..... I. G. Neudachin, B. T. Porodnov, P. E. Suetin
515 (818) Flow of low-density gases in a capillary grid ..... B. T. Porodnov, V. D. Akin'shin, V. I. Kichaev, S. F. Borisov, P. E. Suetin
519 (824) Transient molecular effusion characteristics ..... Yu. N. Lyubitov, V. Z. Belen'kii
523 (830) A transaxial lens ..... V. M. Kel'man, L. M. Nazarenko, E. M. Yakushev
526 (835) Differential electromagnetic characteristics at the interface between ice and water in the ocean ..... V. V. Bogorodskii, V. P. Tripol'nikov

BRIEF COMMUNICATIONS

529 (839) Evolution of monochromatic whistler and plasma-wave packets in a collisionless plasma ..... Ya. N. Istomin
531 (841) Diffraction of a plane electromagnetic wave by a conducting plane with a projection ..... A. A. Zilbergleit

533 (844) Reflection of electromagnetic waves by a moving plasma . V. I. Miroshnichenko
535 (848) A useful function in the thermodynamics of irreversible processes. . . . . A. V. Pamfilov, A. I. Lopushanskaya, L. B. Tsvetkova
538 (851) Effect of ion current on the measurement of the electron energy distribution function by the second-derivative method. . . . . V. A. Dovzhenko, A. P. Ershov, G. S. Solntsev
540 (854) Energy dependence of the focusing of ions by crystals . . . E. S. Mashkova, V. A. Molchanov, A. D. Pavlova
541 (855) Steady-state study of the temperature dependence of the mutual-diffusion coefficients of certain gases. . . . . N. D. Kosov, B. P. Solonitsyn
543 (857) Statistical characteristics of the turbulent wake behind a supersonic sphere . . . . V. G. Ivanov, G. I. Mishin, S. N. Palkin
546 (861) Gas focusing of a negative-ion beam . . . . M. D. Gabovich, A. P. Naida, I. M. Protsenko, L. S. Simonenko, I. A. Soloshenko
548 (863) Time characteristics of the near radiation field of the injection laser. . . . . Zh. I. Alferov, V. N. Deryagin, L. E. Marasin, Yu. V. Popov, E. L. Portnoi
549 (864) Frequency-doubling single-mode laser for picosecond pulses . . . . A. M. Bonch-Bruevich, A. M. Tkachuk, A. A. Fedorov
552 (868) Unidirectional cw oscillation in a solid state ring laser with a return mirror . . . . A. A. Mak, V. I. Ustyugov, V. A. Fromzel', M. M. Khaleev
554 (870) Measurement of plasma ion temperature by a thin probe with $T_i \gg T_e$. . . . . B. I. Kanaev, E. E. Yushmanov
556 (873) Effect of instrumental noise on a system with two spin oscillators using Cs^{133} and He^3. . . . . R. A. Zhitnikov, V. V. Semenov, P. A. Klyushkin
558 (875) Method for determining the absolute characteristics of CF_3I laser emission . . . . V. S. Komarov, V. G. Seleznev, G. A. Skorobogatov
561 (878) Electrostatic analyzer for wide beams. . . . . V. G. Kovalenko, B. V. Polenov
563 (881) Vacuum-UV and soft x-ray emission in a magnetoplasma compressor . . . . P. E. Kovrov, L. G. Tokarev
565 (883) Multiple recording and erasure of optical information in certain glassy chalcogenides . . . . V. V. Korsakov, V. I. Nalivaiko, V. G. Remesnik, V. G. Tsukerman
567 (886) Temperature dependence of the dielectric permittivity of single-crystal TiO_2 in the submillimeter range . . . . . A. A. Volkov, N. A. Irisova, G. V. Kozlov
569 (888) Low-voltage gun with a resonator for formation of electron bunches in a linear accelerator. . . . . V. A. Boiko, R. M. Voronkov, V. A. Danilichev
572 (891) Parametric excitation of surface waves in a spatially modulated electron beam. . . . . A. I. Pasynok, N. S. Repalov

THEORETICAL AND MATHEMATICAL PHYSICS

711 (1121) The magnetostatic problem for thin closed shells...... I. P. Krasnov
713 (1125) Microwave propagation in a low-loss dielectric....... L. É. Rikenglaz
715 (1129) Maximum current of a beam with finite phase volume... G. I. Trubnikov, V. S. Kuznetsov

PLASMA

717 (1133) Symmetry of high-frequency plasma motions......... A. A. Zhmudskii, V. B. Taranov
719 (1137) Aperiodic instability in a plasma with external feedback........................... A. N. Igritskii
722 (1143) Magnetodrift waves in a finite-β plasma............ N. M. Ryzhov, V. L. Sizonenko, V. A. Suprunenko, E. A. Sukhomlin, Yu. V. Gutarev
726 (1151) Wave interaction in a thin plasma sheath............ A. V. Pashchenko, B. N. Rutkevich
732 (1161) Generation of drift waves by an rf field near the lower hybrid frequency......................... Yu. F. Baranov, D. G. Bulyginskii, M. I. Vil'dzhyunas, B. V. Galaktionov, N. V. Shustova
736 (1168) Coaxial plasma injector with programmed injection.... V. A. Burtsev, V. N. Litunovskii, M. P. Nadgornaya
741 (1176) Conversion of neutral hydrogen into protons in dense plasmas............................. T. A. Bazilevskaya, L. I. Krupnik, N. G. Shulika
745 (1183) Model for the low-voltage arc. I. Stationary solution... Yu. Yu. Abramov, G. G. Gladush
748 (1188) Model for the low-voltage arc. II. Stability......... Yu. Yu. Abramov, G. G. Gladush
751 (1193) Interferometer measurement of the neutral cesium distribution in a short low-voltage arc............ Yu. L. Serov, I. P. Yavor
755 (1200) Formation of a narrow gas jet in vacuum............ G. I. Dimov, V. Ya. Savkin
759 (1206) Electron-beam excited crossed-field discharge....... V. A. Saenko, M. M. Kasumov

ACCELERATORS

762 (1210) Extraction of synchrotron radiation from a cyclic electron accelerator with a strong magnetic field..... V. I. Kvochka, V. S. Panasyuk, V. F. Romanovskii, L. N. Samoilov, A. A. Sokolov, B. M. Stepanov, Yu. M. Tereshkin
767 (1218) Resonator with azimuthally varying end plates........ M. F. Vorogushin, V. I. Petrunin
770 (1222) Azimuthal and vertical motion in an accelerator with azimuthally varying electric field............... M. F. Vorogushin, V. I. Petrunin
773 (1228) Spatial and energy parameters of the relativistic electron beam of the Rius-5 accelerator........... A. T. Altyntsev, V. I. Koroteev

GENERAL

775 (1232) Kinetics of gasdynamic lasers. Effect of nozzle geometry on inversion........................ A. S. Biryukov, L. A. Shelepin
782 (1244) Photochemical waves in a medium with a branch-chain conversion mechanism....................... A. N. Oraevskii, V. P. Pimenov, V. A. Shcheglov
787 (1253) Direct and cascade four-photon parametric scattering of light in $LiIO_3$ crystals..................... S. M. Arakelyan, V. G. Tunkin, A. I. Kholodnykh, A. S. Chirkin
793 (1262) Vaporization and boiling of liquid metal in an exploding wire................................. M. M. Martynyuk
798 (1271) Approximate similarity relations in the electrical explosions of underwater conductors............ E. V. Krivitskii, V. K. Sholom
802 (1277) Breakdown caused by electron bombardment of the surface of an alloy electrode.................. N. V. Belan, G. I. Kostyuk, V. A. Pimkin
804 (1280) Emission characteristics of an explosive gallium cathode.............................. G. N. Fursei, V. M. Zhukov
808 (1287) Atomic recombination on a solid surface........... V. P. Pinchuk, A. N. Gorban', V. G. Kornich
811 (1292) Absorption of bismuth on tungsten. I. Steady-state processes.............................. M. A. Mittsev

815 (1298) Effects of cleaning on adsorption by germanium single crystals . . . . . Yu. I. Belyakov, M. P. Volkov, T. N. Kompaniets
817 (1302) Monte Carlo analysis of ion scattering in a mass spectrometer . . . . . M. L. Aleksandrov, L. N. Gall', N. S. Pliss
820 (1306) Behavior of molten salts in strong electric fields . . . . . A. Z. Éfendiev, O. M. Shabanov, S. M. Gadzhiev S. M. Tagirov
824 (1312) Shielding properties of superconducting shields . . . . . S. I. Bondarenko, S. S. Vinogradov, G. A. Gogadze, S. S. Perepelkin, V. I. Sheremet

1116 (1788) Plasma decay instability in crossed fields — V. I. Farenik, V. V. Vlasov, A. M. Rozhkov, A. A. Kozharin

1118 (1790) Titanium adsorption on tungsten — Yu. K. Ustinov, S. V. Fedichev

1120 (1792) Effect of the radiation density on ion drift velocity in a cadmium–helium laser — G. N. Tolmachev, E. L. Latush, V. S. Mikhalevskii

1122 (1795) Dielectric strength of a vacuum gap with electrodes irradiated with He^+ and H^+ ions — A. P. Solodovnikov, Yu. M. Khirnyi

1123 (1796) Hydrodynamic stability of the Uragan stellarator — V. M. Zalkind, Yu. K. Kuznetsov, V. K. Pashnev, V. M. Tonkopryad

1126 (1799) Equations and boundary conditions for a three-dimensional quasistationary field — V. I. Yurchenko

1129 (1802) Steady-state operation of a surface-ionization thermionic converter — N. V. Volkov, Yu. K. Gus'kov, Yu. I. Kostikov, V. P. Pashchenko

1131 (1804) Transient thermionic-field emission from a point cathode — E. A. Litvinov, A. F. Shubin

Soviet Physics – Technical Physics Vol. 19, No. 9, March 1975

(Russian original: Zh. Tekh. Fiz., Vol. 44, No. 9, pp. 1809-2032, September 1974)

1133 (1809) Recent developments in surface ionization (review) É. Ya. Zandberg

PLASMA

1145 (1829) Transverse-current plasma instability D. G. Lominadze, V. L. Sizonenko
1150 (1839) Plasma instability due to an anisotropic electron distribution D. G. Lominadze, V. L. Sizonenko
1154 (1846) Stochastic acceleration of electrons in nanosecond discharges L. P. Babich
1157 (1852) Nonlinear interaction between a monochromatic ion-acoustic wave and a plasma V. P. Indykul
1160 (1857) High-frequency instabilities in an inhomogeneous, anisotropic finite-β plasma V. D. Egorenkov, A. I. Pyatak
1163 (1862) Modulation of microwaves by density fluctuations in a plasma L. A. Dushin, A. V. Serikov, A. I. Skibenko, E. V. Krivorukov, I. P. Fomin
1168 (1871) Measurement of plasma density distribution with a rectangular microwave cavity I. N. Moskalev
1171 (1877) Diffusion of quasistationary helical magnetic fields into the interior of cylindrical chambers. II V. F. Aleksin, S. S. Romanov

QUANTUM ELECTRONICS

1174 (1883) Solid-state laser with externally forced Q switching N. M. Galaktionova, A. A. Mak, A. P. Khyuppenen
1177 (1889) Aberrations in systems with plane and spherical detection apertures V. V. Izokh, A. V. Sergeev, I. Yu. Shmidov
1181 (1896) Correlation analysis of fine-structure images A. A. Kolesnikov, N. V. Lapteva

ACCELERATORS

1185 (1903) Coherent instability of a beam in a vacuum chamber with an irregular boundary E. S. Masunov
1188 (1909) Magnetic-field transport of a high-current electron beam A. V. Agafonov, V. S. Voronin, A. N. Lebedev, K. N. Pazin

ELECTRONICS

1193 (1917) Electron energy spectrum in a high-current vacuum diode S. P. Bugaev, V. I. Koshelev, M. N. Timofeev
1196 (1922) Multiphase, uniform, secondary-emission microwave discharge at a solid surface G. S. Luk'yanchikov
1200 (1929) Discharge in a cylindrical diode with surface ionization V. P. Osoka, A. V. Potarov
1205 (1938) Kinetic energy of ions produced by surface ionization. I. Distribution over the velocity components L. V. Sumin
1210 (1946) Dielectric strength of spark gaps following strong current pulses E. P. Bel'kov
1214 (1952) Electrical conductivity of a pseudoliquefied layer in an electric field V. V. Gal', V. I. Knov, K. A. Nikitin
1216 (1955) Multiple scattering of a focused beam of monoenergetic electrons G. N. Vyalov
1219 (1961) Double focusing in a system of 1/r electric and magnetic fields V. V. Zashkvara, V. N. Demin
1221 (1964) Numerical experiments on electron bombardment in crossed fields P. V. Romanov, A. S. Roshal'
1224 (1969) Effect of a high-current relativistic electron beam on a metal B. I. Dmitrenko, L. V. Leskov, G. P. Maksimov, S. L. Nedoseev, V. V. Savichev, V. P. Smirnov, A. M. Spektor

1337 (2159)	Thermionic emission properties of zirconium, hafnium, and titanium nitrides in cesium vapor	M. A. Eremeev, V. S. Neshpor, A. B. Novikov, E. M. Stefanovskaya, V. P. Fedorinov
1342 (2168)	Electron energy spectrum in high-energy nanosecond accelerators	V. V. Kremnev, G. A. Mesyats, V. P. Reznikov

ELECTRONICS

1345 (2174)	Shot noise in a thermionic cathode	A. F. Golubentsev, A. S. Shapovalov
1347 (2178)	Use of a field-emission microscope to measure the pressure of pump oil	V. Ya. Pliskovskii, M. S. Sukonnik, V. A. Shishkin
1352 (2186)	Emission parameters of a field-emission cathode	G. N. Freiberg
1355 (2192)	Composition of adsorbing and desorbing fluxes	Yu. A. Gel'man, V. I. Mikhailov, V. F. Vinogradov, Yu. N. Lyubitov
1359 (2198)	Radial distribution of density and potential in a glow discharge in CO_2 and water	A. I. Maksimov, V. F. Sokolov
1362 (2203)	High-frequency modulation of atomic beams for plasma diagnostics	P. A. Demchenko, L. I. Krupnik, K. A. Leontovich, E. S. Lyangner
1367 (2211)	Doppler profile of an atomic line to the differential excitation cross section	É. S. Parilis, V. Kh. Ferleger

GENERAL

1371 (2217)	Distortion of single turn solenoids in ultrahigh magnetic fields	G. A. Shneerson
1378 (2229)	Dependence of the basic parameters of $Al_xGa_{1-x}As$—GaAs solar converters on temperature and optical intensity	E. B. Vinogradova, M. B. Kagan, N. S. Koroleva, T. L. Lyubashevskaya, T. A. Nuller

1382 (2235) **Excitation of thermoelastic vibrations of a thin plate by a beam of fast charged particles** — **A. I. Kalinichenko, V. T. Lazurik-Él'tsufin**

Soviet Physics – Technical Physics Vol. 19, No. 11, May 1975

(Russian original: Zh. Tekh. Fiz., Vol. 44, No. 11, pp. 2241-2448, November 1974)

THEORETICAL AND MATHEMATICAL PHYSICS

1385 (2241)	Diffraction of electromagnetic waves by a dielectric wedge	A. A. Aleksandrova, N. A. Khizhnyak
1390 (2250)	Propagation of shock waves in inhomogeneous media	R. A. Glatman
1393 (2255)	Ponderomotive forces on a rotating conducting sphere in a time-varying inhomogeneous magnetic field	R. V. Lin'kov, Yu. M. Urman
1399 (2265)	Electromagnetic levitation of a liquid metal droplet with strong skin effect (surface shape and internal pressure)	A. N. Tverdokhlebov, A. L. Shuster
1403 (2272)	Fifth-order spherical aberration in focusing and correcting quadrupole–octupole systems	Ya. G. Lyubchik, T. Ya. Fishkova

PLASMA

1408 (2280)	Mechanism for plasma loss from a magnetic trap	V. I. Volosov
1412 (2286)	Measurement of ion density by the dispersion relation for an ion-beam plasma	M. D. Gabovich, L. P. Katsubo, I. A. Soloshenko
1414 (2290)	Axially symmetric neutralized electron beam	G. N. Vyalov, V. N. Evteev, Yu. M. Zolotaikin, K. N. Ul'yanov
1418 (2296)	Plasma synthesis by injection of an electron beam through an ion source	V. F. Virko, M. D. Gabovich, G. S. Kirichenko, O. K. Nazarenko
1421 (2302)	Measurement of plasma electron temperature with a sinusoidal probe potential	B. I. Kanaev, V. V. Piterskii, E. E. Yushmanov
1424 (2307)	Atomic density in the low-voltage arc in a cesium diode	F. G. Baksht, A. A. Kostin, Yu. L. Serov, I. P. Yavor
1426 (2311)	Free expansion of plasma jets	P. A. Demchenko, L. I. Krupnik, E. S. Lyangner
1429 (2317)	Laser-initiated vacuum discharge	V. P. Kovalenko, A. A. Makarevich, V. A. Rodichkin, A. M. Timonin
1432 (2322)	Effects due to streamer shape	É. D. Lozanskii, D. B. Pontekorvo
1434 (2326)	Electrical breakdown of vacuum gaps under superhigh voltage pulses	I. I. Kalyatskii, G. M. Kassirov, G. S. Smirnov
1436 (2329)	Volt–ampere characteristic of the low-voltage arc. I. Recombination model	P. P. Shcherbinin
1442 (2340)	Gasdynamic model of the spark discharge	Yu. K. Bobrov
1447 (2348)	Development of an inhibited glow discharge	Yu. A. Bystrov, S. A. Ivanov, Yu. F. Radchenko
1449 (2352)	Resistance and inductance of a gas arc	S. I. Barannik, S. B. Vasserman, A. N. Lukin
1454 (2360)	Electrical explosion of the metastable liquid phases of zinc, cadmium, and lead	M. M. Martynyuk, I. Karimkhodzhaev
1458 (2367)	Resistance and enthalpy of refractory exploding wires	M. M. Martynyuk, I. Karimkhodzhaev, V. I. Tsapkov

ELECTRONICS

1462 (2374)	Ion-optical system for shaping high-current ion beams	S. D. Grishin, V. F. Kuzovlev, R. V. Orlov, S. N. Ogorodnikov
1465 (2378)	Elimination of carbon impurities from platinum by heating in an oxygen atmosphere	L. P. Rekova, V. V. Mozgin, L. N. Zvyagintseva, V. N. Bondarenko, Ya. M. Fogel'
1468 (2383)	Radiation yield of ions in liquid dielectrics as a function of temperature and radiation energy	V. I. Ivanov, E. D. Kleshchenko, Yu. P. Sukhanovskii, V. V. Frolov
1471 (2388)	Steady-state electron density in photoionization of aerosol particles	G. V. Karachevtsev, A. A. Fridman

GENERAL

1474 (2393)	Surface evaporation of a solid transparent dielectric under the action of laser radiation	A. M. Bonch-Bruevich, Ya. A. Imas, A. A. Kovalev, P. S. Kondratenko, B. I. Makshantsev
1477 (2398)	Interaction of intense laser radiation with solid targets	L. V. Dubovoi, V. D. Dyatlov, V. I. Kryzhanovskii, A. A. Mak, R. N. Medvedev, A. N. Popytaev, V. A. Serebryakov, V. N. Sizov, A. D. Starikov

BRIEF COMMUNICATIONS

1480 (2404)	Laser compensation for thermal distortion in optical pumping	V. K. Zaitsev, V. A. Il'inskii, A. M. Marugin, V. M. Ovchinnikov
1482 (2405)	Theory of nonequilibrium shock waves	R. A. Glatman, I. V. Ioffe
1484 (2407)	Radio-frequency absorption in a plasma coinfined by rf plugs	K. S. Golovanivskii, V. D. Dougar-Jabon, L. A. Pokhmel'nykh
1486 (2410)	Motion of stable aerosol particles	O. A. Barsegyan, Yu. I. Yalamov
1488 (2412)	Motion of charged particles in a nonneutral plasma	E. N. Agafonova, L. I. Grechikhin
1490 (2414)	Initial stage of a high-current discharge in air	A. F. Aleksandrov, V. V. Perebeinos, A. T. Savichev, I. B. Timofeev
1492 (2416)	Electron energy distribution in a constricted, low-pressure hydrogen discharge	M. A. Abroyan, Yu. M. Kagan, N. B. Kolokolov, B. P. Lavrov
1494 (2417)	Spectral narrowing of a single-mode beam oscillator	V. A. Buts, V. I. Kurilko
1496 (2419)	Stabilization of two-stream instabilities	V. A. Buts
1498 (2421)	Acceleration of plasma electrons in strong electric fields	Z. A. Al'bikov, M. I. Ivanov, V. I. Kazacha, O. V. Kozlov, V. D. Rusanov, S. S. Sobolev,
1500 (2423)	Two modes of operation of an arc plasma source in an external magnetic field	A. G. Korsun, S. A. Meshcheryakov
1502 (2425)	Loss of neutralization for a stable neutralized ion beam	M. D. Gabovich
1504 (2428)	Analysis of magnetic deflection systems	O. M. Vovk, O. Ya. Popov
1505 (2430)	Nonlinear behavior of monochromatic surface waves excited by a beam	A. B. Kitsenko, I. M. Pankratov, K. N. Stepanov
1507 (2432)	Electron lifetimes in atmosphere at high pressure	V. N. Kapinos, Yu. A. Medvedev, N. N. Morozov, B. M. Stepanov
1508 (2433)	Low-frequency helical instability in a high-frequency electric field	V. S. Paverman, D. D. Tskhakaya
1510 (2436)	Method for optical modulation of an electron beam	V. I. Sotnikov
1512 (2438)	Liquid metal droplet with high surface tension in an axially-symmetric electromagnetic field (strong skin effect)	A. N. Tverdokhlebov, A. L. Shuster
1514 (2441)	Solution of the Stefan problem	A. M. Tsybin
1516 (2444)	Stigmatic sectored magnetic analyzer for a multiple-beam mass spectrometer	G. Kh. Chedzhemov

Soviet Physics – Technical Physics Vol. 19, No. 12, June 1975

(Russian original: Zh. Tekh. Fiz., Vol. 44, No. 12, pp. 2449-2692, December 1974)

THEORETICAL AND MATHEMATICAL PHYSICS

1519 (2449)	Rotation of Poynting vector for ultralow-frequency ion waves in an inhomogeneous plasma	Ya. L. Al'pert, R. N. Kaufman
1522 (2454)	Anomalous resistivity of a transverse plasma current at electron-cyclotron harmonics	V. I. Aref'ev, A. A. Chernov
1529 (2467)	Anomalous ion heating in a parametrically unstable plasma	I. S. Baikov, V. P. Silin
1534 (2476)	Transformation of nonlinear MHD waves	G. M. Zaslavskii, S. S. Moiseev, V. V. Mukhin
1538 (2483)	Two-stream flow in a thin plasma slab	A. V. Pashchenko, B. N. Rutkevich

PLASMA

1541 (2489)	Energy balance in Tokamaks in the "plateau–banana" transition	Yu. N. Dnestrovskii, D. P. Kostomarov
1543 (2493)	Anisotropic plasma heating near the lower hybrid frequency	V. M. Glagolev, V. V. Martynenko, Yu. V. Skosyrev
1547 (2500)	Interaction of a hollow electron beam with a plasma	N. M. Zemlyanskii, A. K. Berezin, Ya. B. Fainberg, L. I. Bolotin, S. S. Krivulya
1549 (2504)	Low-pressure self-maintained discharge with suppressed electron drift. I	V. K. Kalashnikov, Yu. V. Sanochkin
1554 (2512)	Low-pressure self-maintained discharge with suppressed electron drift. II	Yu. V. Sanochkin, V. K. Kalashnikov
1558 (2519)	Formation of a plasma focus in a plasma erosion accelerator. II. Energy characteristics of the dense plasma focus	N. P. Kozlov, L. V. Leskov, Yu. S. Protasov, V. I. Khvesyuk
1560 (2523)	Effect of rf ionization on a Hall-current plasma accelerator	I. I. Demidenko, N. S. Lomino, A. I. Morozov, V. G. Padalka
1564 (2529)	Analytic model for the arc regime and the thermionic converter	V. D. Bondarenko, A. I. Loshkarev
1569 (2537)	Dielectric breakdown of detonation products	V. L. Korol'kov, M. A. Mel'nikov, A. P. Tsyplenko
1571 (2539)	Anomalous high emission of a nonevaporating thermionic cathode in an arc	B. Ya. Moizhes, V. A. Nemchinskii
1577 (2548)	High-pressure hot-cathode arc without forced cooling	V. A. Nemchinskii
1579 (2551)	Hot probe measurements in a rarefied streaming plasma	E. M. Netsvetailov, L. V. Nosachev, V. V. Skvortsov
1584 (2559)	Wave excitation at half the gyrofrequency in counterstreaming electron beams	A. P. Timoshenko, D. V. Iremashvili, Yu. K. Udovichenko

QUANTUM ELECTRONICS

1587 (2563)	Mass spectrum of secondary ions ejected from the surface of a single crystal of gallium arsenide by argon ions	A. G. Koval', V. V. Bobkov, Yu. A. Klimovskii, S. S. Strel'chenko, V. V. Shubina, V. V. Lebedev, Ya. M. Fogel'
1590 (2568)	Coherent Compton effect in crystals	V. A. Bushuev, R. N. Kuz'min

GENERAL

1593 (2572)	Transformation of light beams by dynamic correctors using three-dimensional displacement phase holograms	V. G. Sidorovich, D. I. Stasel'ko
1598 (2580)	Electroluminescence spectra of the red luminescent diodes $p\text{-Al}_x\text{Ga}_{1-x}\text{As}-n\text{-Al}_y\text{Ga}_{1-y}\text{As}$ $(y > x)$	V. M. Busov, D. Z. Garbuzov, A. T. Gorelenok, D. S. Kop'ev

BRIEF COMMUNICATIONS

1601 (2585)	Gas temperature in the positive column of a medium-β helium discharge	Yu. M. Kagan, K. K. Paskalev
1604 (2588)	Temperature and electron density in the positive column of a medium-pressure helium discharge	Yu. M. Kagan, K. K. Paskalev
1606 (2591)	Direct current in a metal–selenium–metal structure bounded by an rf plasma	A. D. Andreev, S. I. Lubinskii
1608 (2594)	Measurement of transverse relaxation time T_2 of optically oriented He^4 with an oscillator magnetometer	N. A. Dovator, R. A. Zhitnikov, P. P. Kuleshov
1610 (2595)	Current-convective instability in a three-component plasma	E. Z. Meilikhov

1612 (2598) Effect of a magnetic field on spontaneous mode-locking in a He−Ne laser ($\Lambda = 0.63\ \mu$) — V. Yu. Petrun'kin, V. M. Nikolaev, O. I. Kotov, B. V. L'vov
1614 (2600) Exact solutions of the nonlinear electrodynamic equations — N. G. Puchkova, A. F. Kulish
1616 (2602) Streamer propagation after the voltage termination in a streamer chamber — N. S. Rudenko, V. I. Smetanin
1618 (2604) Electron-optical properties of postdeflection quadrupole lenses — T. Ya. Fishkova
1620 (2607) Frequency locking in a 3.39 μ laser — E. Yu. Andreeva, S. N. Gulyaev, D. K. Terekhin
1622 (2609) Efficiency of the scattering of "unstable" charged particles in quadrupole mass spectrometers — É. P. Sheretov, B. I. Kolotilin, M. P. Safonov
1625 (2613) Reflection of a high-current relativistic electron beam from a conducting surface — A. N. Didenko, A. I. Ryabchikov, V. A. Tuzov, Yu. P. Usov
1627 (2615) Thermal diffusion in a mixture of cesium vapor and helium — E. S. Bekmukhambetov, V. A. Donov
1629 (2617) Parametric excitation of helicon waves in a plasma by modulated radio frequency waves — V. S. Paverman, D. D. Tskhakaya
1631 (2620) Electrical strength of nitrogen and hydrogen at high pressures — É. A. Avilov, I. V. Belkin
1633 (2622) Coherent phase oscillations of electrons in a synchrotron — M. M. Nikitin
1635 (2623) Neutral particles from the interaction of laser radiation with a solid target — Yu. A. Bykovskii, N. M. Vasil'ev, I. D. Laptev, V. N. Nevolin
1636 (2625) Certain integral relations in the kinetic theory of gases — S. P. Bakanov
1639 (2629) Connection of magnetic lines of force in a neutral layer — A. T. Altyntsev, V. I. Krasov
1641 (2632) Correction to the paper "Resonant properties of a pulsating dielectric sphere" — A. G. Nerukh, N. A. Khizhnyak

ANNUAL INDEX

1643 Analytic subject index to volume 19
1664 Author index to volume 19

SUBJECT INDEX TO VOLUME 19

Papers are arranged in ascending page number order.

---

1. COMMUNICATION, EDUCATION, HISTORY, AND PHILOSOPHY

Correction to the paper "Resonant properties of a pulsating dielectric sphere" —A. G. Nerukh and N. A. Khizhnyak. 19(12), 1641 (Jun. 1975); CPM-7508X0515

2. MATHEMATICAL METHODS IN PHYSICS

Solution of the Stefan problem —A. M. Tsybin. 19(11), 1514–5 (May 1975); CPM-7506X1268

Monte Carlo analysis of ion scattering in a mass spectrometer —M. L. Aleksandrov, L. N. Gall', and N. S. Pliss. 19(6), 817–9 (Dec. 1974); CPM-7501X0817

3. CLASSICAL AND QUANTUM PHYSICS; MECHANICS AND FIELDS

3.50.– Classical electrodynamics and classical field theory

Resonance properties of a pulsating dielectric sphere —A. G. Nerukh and N. A. Khizhnyak. 19(2), 166–8 (Aug. 1974); CPM-7408X1430

Potential factors for an inhomogeneous ellipsoid —M. L. Levin and R. Z. Muratov. 19(2), 169–70 (Aug. 1974); CPM-7408X1433

Resonator with azimuthally varying end plates —M. F. Vorogushin and V. I. Petrunin. 19(6), 767–9 (Dec. 1974); CPM-7501X0767

Diffusion of quasistationary helical magnetic fields into the interior of cylindrical chambers. II. —V. F. Aleksin and S. S. Romanov. 19 (9), 1171–3 (Mar. 1975); CPM-7505X0593

Ponderomotive forces on a rotating conducting sphere in a time-varying inhomogeneous magnetic field —R. V. Lin'kov and Yu. M. Urman. 19(11), 1393–8 (May 1975); CPM-7506X1147

3.50.C Classical field theory

Charged-particle motion in a dipole magnetic field —L. G. Glikman. 19(4), 435–40 (Oct. 1974); CPM-7412X0219

Rectangular conducting wedge in a moving electromagnetic field —I. D. Maergoiz and L. P. Nizhnik. 19(10), 1281–6 (Apr. 1975); CPM-7506X0215

Exact solutions of the nonlinear electrodynamic equations —N. G. Puchkova and A. F. Kulish. 19(12), 1614–5 (Jun. 1975); CPM-7508X0488

Correction to the paper "Resonant properties of a pulsating dielectric sphere" —A. G. Nerukh and N. A. Khizhnyak. 19(12), 1641 (Jun. 1975); CPM-7508X0515

3.50.F Electrostatics and magnetostatics

The magnetostatic problem for thin closed shells —I. P. Krasnov. 19 (6), 711–2 (Dec. 1974); CPM-7501X0711

Computer calculation of quasistationary pulsed magnetic fields —V. I. Yurchenko. 19(8), 1025–30 (Feb. 1975); CPM-7504X1449

Flux loss in the production of ultrastrong fields by rapid compression of conducting shells —V. I. Yurchenko. 19(8), 1031–3 (Feb. 1975); CPM-7504X1455

Equations and boundary conditions for a three-dimensional quasistationary field —V. I. Yurchenko. 19(8), 1126–8 (Feb. 1975); CPM-7504X1550

Graphical methods for constructing trajectories of small particles in electrostatic fields —N. I. Shtepa. 19(9), 1253–5 (Mar. 1975); CPM-7505X0675

Magnetic topography of toroidal systems —M. N. Skoblik, V. E. Ziser, A. V. Georgievskii, and V. G. Peletminskaya. 19(10), 1277–80 (Apr. 1975); CPM-7506X0211

Electromagnetic levitation of a liquid metal droplet with strong skin effect (surface shape and internal pressure) —A. N. Tverdokhlebov and A. L. Shuster. 19(11), 1399–402 (May 1975); CPM-7506X1153

Liquid metal droplet with high surface tension in an axially-symmetric electromagnetic field (strong skin effect) —A. N. Tverdokhlebov and A. L. Shuster. 19(11), 1512–3 (May 1975); CPM-7506X1266

3.50.J Electromagnetic wave theory

Round metal–optical waveguide filled with a two-layer dielectric —V. A. Pruzhanovskii. 19(1), 3–8 (Jul. 1974); CPM-7407X1515

Diffraction of a plane electromagnetic wave by a conducting plane with a projection —A. A. Zilbergleit. 19(4), 531–2 (Oct. 1974); CPM-7412X0315

Two-dimensional diffraction on a system of straight segments (shields) —G. A. Grinberg. 19(5), 581–5 (Nov. 1974); CPM-7501X0375

Radiation from a charged particle moving close to an anisotropic dielectric —A. I. Plis and N. M. Safikhodzhaev. 19(7), 865–7 (Jan. 1975); CPM-7503X0753

Radiation emitted by charged particles trapped by plane electromagnetic waves —V. Ya. Davydovskii and A. S. Ukolov. 19 (8), 1057–60 (Feb. 1975); CPM-7504X1481

Radiation of electromagnetic waves by a modulated electron beam —S. G. Pankratov. 19(9), 1248–50 (Mar. 1975); CPM-7505X0670

Skin effect in a constant magnetic field —Z. K. Yankauskas, V. I. Chesonis, and V. G. Skripnik. 19(9), 1251–2 (Mar. 1975); CPM-7505X0673

Electromagnetic pulse radiated by a moving charged bunch in matter —N. A. Zvonnikov. 19(10), 1290–2 (Apr. 1975); CPM-7506X0224

Diffraction of electromagnetic waves by a dielectric wedge —A. A. Aleksandrova and N. A. Khizhnyak. 19(11), 1385–9 (May 1975); CPM-7506X1139

3.80.+ General theory of scattering

Microwave propagation in a low-loss dielectric —L. É. Rikenglaz. 19 (6), 713–4 (Dec. 1974); CPM-7501X0713

Diffraction of electromagnetic waves by a dielectric wedge —A. A. Aleksandrova and N. A. Khizhnyak. 19(11), 1385–9 (May 1975); CPM-7506X1139

5. STATISTICAL PHYSICS AND THERMODYNAMICS

5.60.– Transport processes, theory

Fundamentals of heat-pipe theory and design —M. M. Levitan and T. L. Perel'man. 19(8), 983–95 (Feb. 1975); CPM-7504X1407

Heat transport problems with time-varying boundary conditions or moving boundaries (Stefan problem) —G. A. Grinberg. 19(10), 1267–72 (Apr. 1975); CPM-7506X0201

Stefan problem with motion of the phase-transition surface described by $y(\tau)=\sqrt{A\tau^2+B\tau+h^2}$ —O. M. Chekmareva. 19(10), 1273–6 (Apr. 1975); CPM-7506X0207

5.90.+ Other topics in statistical physics and thermodynamics

A useful function in the thermodynamics of irreversible processes —A. V. Pamfilov, A. I. Lopushanskaya, and L. B. Tsvetkova. 19(4), 535–7 (Oct. 1974); CPM-7412X0319

Theory of nonequilibrium shock waves —R. A. Glatman and I. V. Ioffe. 19(11), 1482–3 (May 1975); CPM-7506X1236

Certain integral relations in the kinetic theory of gases —S. P. Bakanov. 19(12), 1636–8 (Jun. 1975); CPM-7508X0510

6. MEASUREMENT SCIENCE, GENERAL LABORATORY TECHNIQUES, AND INSTRUMENTATION SYSTEMS

Distributed systems for feedback control of a tokamak plasma —V. F. Gubarev and Yu. I. Samoilenko. 19(4), 463–7 (Oct. 1974); CPM-7412X0247

Effect of instrumental noise on a system with two spin oscillators using Cs^{133} and He^3 —R. A. Zhitnikov, V. V. Semenov, and P. A. Klyushkin. 19(4), 556–7 (Oct. 1974); CPM-7412X0340

Direct and cascade four-photon parametric scattering of light in $LiIO_3$ crystals —S. M. Arakelyan, V. G. Tunkin, A. I. Kholodnykh, and A. S. Chirkin. 19(6), 787–92 (Dec. 1974); CPM-7501X0787

7. SPECIFIC INSTRUMENTATION OF GENERAL USE IN PHYSICS

7.30.– Vacuum production and techniques

Two-omegatron study of the pumping characteristics of an NÉM-300 magnetic discharge pump for a mixture of gases —M. K. Bulgakov and V. G. Rogozinskii. 19(3), 427–8 (Sep. 1974); CPM-7412X1113

Titanium-pump system for hydrogen —K. G. Mirzoev, V. G. Rogozinskii, and V. L. Ushkov. 19(3), 432–3 (Sep. 1974); CPM-7412X1118

NÉM-1T magnetic-discharge pumps in the vacuum system of the 1–100 linear accelerator —O. N. Krokhina and K. G. Mirzoev. 19 (5), 698–9 (Nov. 1974); CPM-7501X0492

7.72.+ Particle beam production and handling, targets

Efficiency of internal targets in the accelerator at the Institute of High-Energy Physics —V. I. Gridasov, K. P. Myznikov, and V. N. Chepegin. 19(7), 922–5 (Jan. 1975); CPM-7503X0810

Multiple-aperture ion source for electromagnetic mass separator —S. V. Lebedev. 19(7), 968 (Jan. 1975); CPM-7503X0856

Cell for forming electron beams of arbitrary shape in a high-voltage gaseous discharge —I. V. Vagner, É. I. Bolgov, V. F. Grakun, V. L. Gokhfel'd, and V. A. Kudlai. 19(8), 1042–5 (Feb. 1975); CPM-7504X1466

Pulsed ion beams from a high-current plasma diode —B. A. Tskhadaya, A. A. Plyutto, and K. V. Suladze. 19(8), 1108–9 (Feb. 1975); CPM-7504X1532

Ion-optical system for shaping high-current ion beams —S. D. Grishin, V. F. Kuzovlev, R. V. Orlov, and S. N. Ogorodnikov. 19 (11), 1462–4 (May 1975); CPM-7506X1216

7.75.+ Mass spectrometers and mass spectrometry techniques

Line shape of a quadrupole mass spectrometer —G. I. Slobodenyuk. 19(2), 292–3 (Aug. 1974); CPM-7408X1556

Monte Carlo analysis of ion scattering in a mass spectrometer —M. L. Aleksandrov, L. N. Gall', and N. S. Pliss. 19(6), 817–9 (Dec. 1974); CPM-7501X0817

Multiple-aperture ion source for electromagnetic mass separator —S. V. Lebedev. 19(7), 968 (Jan. 1975); CPM-7503X0856

Double focusing in a system of $1/r$ electric and magnetic fields —V. V. Zashkvara and V. N. Demin. 19(9), 1219–20 (Mar. 1975); CPM-7505X0641

Stigmatic sectored magnetic analyzer for a multiple-beam mass spectrometer —G. Kh. Chedzhemov. 19(11), 1516–7 (May 1975); CPM-7506X1270

Efficiency of the scattering of "unstable" charged particles in quadrupole mass spectrometers —É. P. Sheretov, B. I. Kolotilin, and M. P. Safonov. 19(12), 1622–4 (Jun. 1975); CPM-7508X0496

7.90.+ Other topics in specialized instrumentation

Measurement of statistical parameters of scattering particles in laminar flow by Doppler spectroscopy —A. P. Ivanov, A. Ya. Khairullina, and A. P. Chaikovski. 19(2), 267–70 (Aug. 1974); CPM-7408X1531

Strobe unit for measuring luminescence in the range 10^{-7}–$2\cdot10^{-10}$ sec —V. A. Bonch-Bruevich and N. A. Tolstoi. 19(2), 284–6 (Aug. 1974); CPM-7408X1548

Sign of the change in optical path length in a laser interferometer with feedback —I. M. Belousova and A. F. Zapryagaev. 19(6), 829–30 (Dec. 1974); CPM-7501X0829

Hologram interferometry for vibration analysis —V. S. Listovets and Yu. I. Ostrovskii. 19(7), 847–60 (Jan. 1975); CPM-7503X0735

Fundamentals of heat-pipe theory and design —M. M. Levitan and T. L. Perel'man. 19(8), 983–95 (Feb. 1975); CPM-7504X1407

Use of a field-emission microscope to measure the pressure of pump oil —V. Ya. Pliskovskii, M. S. Sukonnik, and V. A. Shishkin. 19 (10), 1347–51 (Apr. 1975); CPM-7506X0281

Measurement of transverse relaxation time T_2 of optically oriented He^4 with an oscillator magnetometer–N. A. Dovator, R. A. Zhitnikov, and P. P. Kuleshov. 19(12), 1608–9 (Jun. 1975); CPM-7508X0482

28. NUCLEAR ENGINEERING AND NUCLEAR POWER STUDIES

Impossibility of shielding against the rf radiation of a thermonuclear reactor with a cold-plasma sheath —A. S. Chikhachev. 19(5), 685 (Nov. 1974); CPM-7501X0479

Energy balance in Tokamaks in the "plateau—banana" transition region —Yu. N. Dnestrovskii and D. P. Kostomarov. 19(12), 1541–2 (Jun. 1975); CPM-7508X0415

29. EXPERIMENTAL METHODS AND INSTRUMENTATION FOR ELEMENTARY-PARTICLE AND NUCLEAR PHYSICS

29.15.+ Electrostatic and linear particle accelerators

Multiple-section linear electron accelerator with synchronized oscillators —V. F. Vikulov, V. A. Volodin, and O. S. Milovanov. 19(7), 930–1 (Jan. 1975); CPM-7503X0818

Control of output energy in linear electron accelerators —V. N. Golovin and N. P. Sobenin. 19(7), 932–4 (Jan. 1975); CPM-7503X0820

Self-excited waveguide buncher —N. M. Gavrilov and A. V. Nesterovich. 19(8), 1085–6 (Feb. 1975); CPM-7504X1509

29.20.– Cyclic accelerators

Aberrations in a straight ion-optical accelerator —E. I. Gerasimov, A. I. Solnyshkov, and G. V. Tarvid. 19(1), 131–3 (Jul. 1974); CPM-7407X1643

High-power nanosecond electron accelerator with inductive storage —B. M. Koval'chuk, Yu. A. Kotov, and G. A. Mesyats. 19(1), 136–7 (Jul. 1974); CPM-7407X1648

Beam focusing in an accelerator with inductive energy storage —V. A. Glukhikh, O. A. Gusev, E. G. Komar, V. S. Kuznetsov, M. P. Svin'in, and R. P. Fidel'skaya. 19(3), 366–7 (Sep. 1974); CPM-7412X1052

High-current pulsed electron accelerator with an annular beam —M. I. Avramenko, V. A. Glukhikh, O. A. Gusev, E. G. Komar, O. L. Komarov, V. S. Kuznetsov, A. S. Perlin, and M. P. Svin'in. 19(3), 368–70 (Sep. 1974); CPM-7412X1054

Transmission of a high-current relativistic beam through a gas —Yu. V. Tkach, I. I. Magda, G. V. Skachek, S. S. Pushkarev, and I. P. Panchenko. 19(3), 412–3 (Sep. 1974); CPM-7412X1098

Linear accelerator for beam injection into a slowly rising magnetic field —D. G. Borisov, A. I. Gryzlov, V. M. Levin, and A. V. Ryabtsov. 19(4), 509–10 (Oct. 1974); CPM-7412X0293

Low-voltage gun with a resonator for formation of electron bunches in a linear accelerator —V. A. Boiko, R. M. Voronkov, and V. A. Danilichev. 19(4), 569–71 (Oct. 1974); CPM-7412X0353

Inductive energy storage in pulsed accelerators —V. A. Glukhikh, O. A. Gusev, E. G. Komar, and M. P. Svin'in. 19(5), 660–1 (Nov. 1974); CPM-7501X0454

Shaping of voltage pulses by discharging an inductive storage bank with a charged-particle beam —O. A. Gusev, E. G. Komar, V. B. Markov, and E. M. Mellekh. 19(5), 662–3 (Nov. 1974); CPM-7501X0456

Maximum current of a beam with finite phase volume —G. I. Trubnikov and V. S. Kuznetsov. 19(6), 715–6 (Dec. 1974); CPM-7501X0715

Extraction of synchroton radiation from a cyclic electron accelerator with a strong magnetic field —V. I. Kvochka, V. S. Panasyuk, V. F. Romanovskii, L. N. Samoilov, A. A. Sokolov, B. M. Stepanov, and Yu. M. Tereshkin. 19(6), 762–6 (Dec. 1974); CPM-7501X0762

Resonator with azimuthally varying end plates —M. F. Vorogushin and V. I. Petrunin. 19(6), 767–9 (Dec. 1974); CPM-7501X0767

Azimuthal and vertical motion in an accelerator with azimuthally varying electric field —M. F. Vorogushin and V. I. Petrunin. 19(6), 770–2 (Dec. 1974); CPM-7501X0770

Spatial and energy parameters of the relativistic electron beam of the Rius-5 accelerator —A. T. Altyntsev and V. I. Koroteev. 19(6), 773–4 (Dec. 1974); CPM-7501X0773

Phase motion of particles in an accelerator with an azimuthally varying electric field —M. F. Vorogushin and V. I. Petrunin. 19(7), 926–9 (Jan. 1975); CPM-7503X0814

29.20.D Storage rings

Coherent instability of a beam in a vacuum chamber with an irregular boundary —E. S. Masunov. 19(9), 1185–7 (Mar. 1975); CPM-7505X0607

29.20.L Synchrotrons

Coherent phase oscillations of electrons in a synchrotron —M. M. Nikitin. 19(12), 1633–4 (Jun. 1975); CPM-7508X0507

29.25.– Particle sources and targets, preparation and technology

Production of an ion beam by a magnetic system with opposed fields —V. B. Glasko, A. G. Sveshnikov, and N. N. Semashko. 19(2), 201–5 (Aug. 1974); CPM-7408X1465

Efficient ion source —D. Kh. Abdrashitova, V. G. Babaev, and M. B. Guseva. 19(2), 264–6 (Aug. 1974); CPM-7408X1528

Efficiency of internal targets in the accelerator at the Institute of High-Energy Physics —V. I. Gridasov, K. P. Myznikov, and V. N. Chepegin. 19(7), 922–5 (Jan. 1975); CPM-7503X0810

Energy spectra of scattered particles in proton bombardment of a metal target —G. I. Zhabrev, V. A. Kurnaev, and V. G. Tel'kovskii. 19(7), 978–9 (Jan. 1975); CPM-7503X0866

Ion energy spectra and collective effects in a Penning ion source —V. I. Farenik, V. V. Vlasov, A. M. Rozhkov, and A. A. Kozharin. 19 (9), 1258–9 (Mar. 1975); CPM-7505X0680

29.90.+ Other topics in high-energy and nuclear experimental methods and instrumentation

Proton extraction from the 70-GeV accelerator for the Ludmila liquid-hydrogen chamber (extraction system S) —A. A. Aseev, A. I. Drozhdin, B. A. Zelenov, É. A. Merker, L. L. Moizhes, K. P. Myznikov, A. A. Roshchin, V. M. Tatarenko, M. A. Kholodenko, A. D. Artemov, L. N. Vaulin, V. I. Gordin, I. I. Kovalevskii, V. N. Rozhkov, M. M. Suvorov, A. S. Sudarushkin, and V. I. Chuiko. 19 (1), 70–6 (Jul. 1974); CPM-7407X1582

Electron spectrometer for electric excitation of nuclei in a storage ring —D. M. Nikolenko and S. G. Popov. 19(2), 280–3 (Aug. 1974); CPM-7408X1544

NÉM-1T magnetic-discharge pumps in the vacuum system of the 1-100 linear accelerator —O. N. Krokhina and K. G. Mirzoev. 19 (5), 698–9 (Nov. 1974); CPM-7501X0492

Self-acceleration of an intense electron beam —I. A. Grishaev, A. N. Dedik, V. V. Zakutin, I. I. Magda, Yu. V. Tkach, and A. M. Shenderovich. 19(8), 1087–9 (Feb. 1975); CPM-7504X1511

Parallel-plate capacitor as a charged-particle spectrometer —Yu. D. Kornyushkin. 19(8), 1110–2 (Feb. 1975); CPM-7504X1534

Effects due to streamer shape —É. D. Lozanskii and D. B. Pontekorvo. 19(11), 1432–3 (May 1975); CPM-7506X1186

Streamer propagation after the voltage termination in a streamer chamber —N. S. Rudenko and V. I. Smetanin. 19(12), 1616–7 (Jun. 1975); CPM-7508X0490

32. ATOMIC AND MOLECULAR INTERACTIONS WITH RADIATION, SPECTROSCOPY

32.10.– Atomic spectroscopy

Dynamic magnetic-resonance phenomena —P. S. Kuts and V. S. Mel'nik. 19(1), 110–4 (Jul. 1974); CPM-7407X1622

Surface-ionization determination of the electron affinities of silver and gold —É. Ya. Zandberg, A. G. Kamenev, and V. I. Paleev. 19(3), 385–9 (Sep. 1974); CPM-7412X1071

Doppler profile of an atomic line to the differential excitation cross section —É. S. Parilis and V. Kh. Ferleger. 19(10), 1367–70 (Apr. 1975); CPM-7506X0301

32.20.– Molecular spectroscopy (measurement and phenomenology)

X-ray fluorescence of oxygen in H_2O —L. A. Smirnov. 19(5), 702 (Nov. 1974); CPM-7501X0496

Electromagnetic pulse radiated by a moving charged bunch in matter —N. A. Zvonnikov. 19(10), 1290–2 (Apr. 1975); CPM-7506X0224

33. MAGNETIC RESONANCES AND RELAXATION IN MOLECULES; NQR, MÖSSBAUER EFFECT

Dynamic magnetic-resonance phenomena —P. S. Kuts and V. S. Mel'nik. 19(1), 110–4 (Jul. 1974); CPM-7407X1622

34. ATOMIC AND MOLECULAR COLLISION PROCESSES AND INTERACTIONS

34.50.– Inelastic scattering of atoms and molecules

Conversion of neutral hydrogen into protons in dense plasmas —T. A. Bazilevskaya, L. I. Krupnik, and N. G. Shulika. 19(6), 741–4 (Dec. 1974); CPM-7501X0741

Energy spectra of scattered particles in proton bombardment of a metal target —G. I. Zhabrev, V. A. Kurnaev, and V. G. Tel'kovskii. 19(7), 978–9 (Jan. 1975); CPM-7503X0866

Doppler profile of an atomic line to the differential excitation cross section —É. S. Parilis and V. Kh. Ferleger. 19(10), 1367–70 (Apr. 1975); CPM-7506X0301

34.60.+ Charge transfer

Excitation collisions between magnesium ions and inert gas atoms —V. L. Ovchinnikov, O. B. Shpenik, and I. P. Zapesochnyi. 19(3), 382–4 (Sep. 1974); CPM-7412X1068

Simulation of ion scattering on diatomic molecules —M. L. Aleksandrov, N. S. Pliss, and A. P. Shcherbakov. 19(3), 394–5 (Sep. 1974); CPM-7412X1080

Formation of molecular ions in an alkali discharge —V. N. Paslen and A. M. Przhonskii. 19(5), 705–6 (Nov. 1974); CPM-7501X0499

Scattering of He^+ ions by the core of the He atom —Z. Z. Latypov and A. A. Shaporenko. 19(7), 976–7 (Jan. 1975); CPM-7503X0864

34.90.+ Other topics in atomic and molecular collision processes and interactions

Effect of electron-atom collisions on electron motion in a gas diode —V. I. Babanin and A. Ya. Énder. 19(1), 60–5 (Jul. 1974); CPM-7407X1572

Excitation collisions between magnesium ions and inert gas atoms —V. L. Ovchinnikov, O. B. Shpenik, and I. P. Zapesochnyi. 19(3), 382–4 (Sep. 1974); CPM-7412X1068

Simulation of ion scattering on diatomic molecules —M. L. Aleksandrov, N. S. Pliss, and A. P. Shcherbakov. 19(3), 394–5 (Sep. 1974); CPM-7412X1080

Flow of low-density gases in a capillary grid —B. T. Porodnov, V. D. Akin'shin, V. I. Kichaev, S. F. Borisov, and P. E. Suetin. 19(4), 515–8 (Oct. 1974); CPM-7412X0299

Energy exchange between electrons and molecular vibrational states in resonance collisions —A. Kh. Mnatsakanyan and G. V. Naidis. 19 (8), 1113–5 (Feb. 1975); CPM-7504X1537

35. EXPERIMENTALLY DERIVED INFORMATION ON ATOMS AND MOLECULES

Determination of ionization potentials and electron affinities of certain elements by extrapolation —A. G. Kamenev, É. Ya. Zandberg, and V. I. Paleev. 19(7), 940–1 (Jan. 1975); CPM-7503X0828

42. OPTICS

42.10.– Propagation and transmission in homogeneous media

Time characteristics of the near radiation field of the injection laser —Zh. I. Alferov, V. N. Deryagin, L. E. Marasin, Yu. V. Popov, and E. L. Portnoi. 19(4), 548 (Oct. 1974); CPM-7412X0332

Reflection of finite amplitude electromagnetic waves from a semiconductor plasma —Yu. F. Filippov. 19(5), 603–6 (Nov. 1974); CPM-7501X0397

Extraction of synchroton radiation from a cyclic electron accelerator with a strong magnetic field —V. I. Kvochka, V. S. Panasyuk, V. F. Romanovskii, L. N. Samoilov, A. A. Sokolov, B. M. Stepanov, and Yu. M. Tereshkin. 19(6), 762–6 (Dec. 1974); CPM-7501X0762

Diffraction of electromagnetic waves by a dielectric wedge —A. A. Aleksandrova and N. A. Khizhnyak. 19(11), 1385–9 (May 1975); CPM-7506X1139

Surface evaporation of a solid transparent dielectric under the action of laser radiation —A. M. Bonch-Bruevich, Ya. A. Imas, A. A. Kovalev, P. S. Kondratenko, and B. I. Makshantsev. 19(11), 1474–6 (May 1975); CPM-7506X1228

Laser compensation for thermal distortion in optical pumping —V. K. Zaitsev, V. A. Il'inskii, A. M. Marugin, and V. M. Ovchinnikov. 19(11), 1480–1 (May 1975); CPM-7506X1234

42.30.– Optical information, image formation and analysis

Nonlinear spherical aberrations and thermoelastic stresses in thermal self-focusing —A. A. Vigasin, Yu. A. Gorokhov, A. P. Sukhorukov, and A. M. Khachatryan. 19(5), 673–5 (Nov. 1974); CPM-7501X0467

Electron-scanning transformation of the potential distribution on an electrostatic target —V. L. Lentsman. 19(5), 678–9 (Nov. 1974); CPM-7501X0472

Optical simulation of a radiator aperture with arbitrary amplitude—phase distribution —M. M. Butusov and Sh. V. Yurevichyus. 19 (6), 833–4 (Dec. 1974); CPM-7501X0833

Correction of third-order angular aberration in a system with two electrostatic mirrors —V. V. Zashkvara. 19(7), 961–2 (Jan. 1975); CPM-7503X0849

Achromatic plasma-lens system —A. I. Morozov and S. V. Lebedev. 19(7), 967 (Jan. 1975); CPM-7503X0855

Aberrations in systems with plane and spherical detection apertures —V. V. Izokh, A. V. Sergeev, and I. Yu. Shmidov. 19(9), 1177–80 (Mar. 1975); CPM-7505X0599

Correlation analysis of fine-structure images —A. A. Kolesnikov and N. V. Lapteva. 19(9), 1181–4 (Mar. 1975); CPM-7505X0603

Fifth-order spherical aberration in focusing and correcting quadrupole—octupole systems —Ya. G. Lyubchik and T. Ya. Fishkova. 19 (11), 1403–7 (May 1975); CPM-7506X1157

42.40.– Holography

Imaging properties of traveling intensity waves in the recording of dynamic three-dimensional holograms —Yu. N. Denisyuk. 19(1), 77–80 (Jul. 1974); CPM-7407X1589

Reversibility of chalcogenide materials in holography —S. B. Gurevich, N. N. Il'yashenko, B. T. Kolomiets, V. M. Lyubin, and M. V. Sukharev. 19(1), 152–3 (Jul. 1974); CPM-7407X1664

Efficiency of light-beam conversion by dynamic three-dimensional phase holograms —D. I. Stasel'ko and V. G. Sidorovich. 19(3), 361–5 (Sep. 1974); CPM-7412X1047

Multiple recording and erasure of optical information in certain glassy chalcogenides —V. V. Korsakov, V. I. Nalivaiko, V. G. Remesnik, and V. G. Tsukerman. 19(4), 565–6 (Oct. 1974); CPM-7412X0349

Holography of raster objects —Sh. D. Kakichashvili. 19(5), 696–7 (Nov. 1974); CPM-7501X0490

Optical simulation of a radiator aperture with arbitrary amplitude—phase distribution —M. M. Butusov and Sh. V. Yurevichyus. 19 (6), 833–4 (Dec. 1974); CPM-7501X0833

Hologram interferometry for vibration analysis —V. S. Listovets and Yu. I. Ostrovskii. 19(7), 847–60 (Jan. 1975); CPM-7503X0735

Transformation of light beams by dynamic correctors using three-dimensional displacement phase holograms —V. G. Sidorovich and D. I. Stasel'ko. 19(12), 1593–7 (Jun. 1975); CPM-7508X0467

42.55.+ Masers

Microwave maser with nonrelativistic electrons —A. S. Dement'ev and Yu. G. Pavlenko. 19(5), 694–5 (Nov. 1974); CPM-7501X0488

42.60.– Lasers

Use of plasma accelerator for optical pumping of lasers —N. P. Kozlov and Yu. S. Protasov. 19(3), 358–60 (Sep. 1974); CPM-7412X1044

42.60.C Gas lasers

Ionization and recombination coefficients in a discharge excited by fast electrons —Yu. I. Bychkov, Yu. D. Korolev, and A. P. Khuzeev. 19(1), 140–1 (Jul. 1974); CPM-7407X1652

Quenching in the CF_3I photodissociation laser —G. A. Skorobogatov, V. M. Tret'yak, and V. S. Komarov. 19(4), 495–8 (Oct. 1974); CPM-7412X0279

Energy input in electrical ionization lasers —Yu. I. Bychkov, Yu. D. Korolev, Yu. A. Kurbatov, and G. A. Mesyats. 19(4), 499–502 (Oct. 1974); CPM-7412X0283

Characteristics of the electrical ionization CO_2 laser —Yu. I. Bychkov, Yu. A. Kurbatov, and V. V. Savin. 19(4), 506–8 (Oct. 1974); CPM-7412X0290

Method for determining the absolute characteristics of CF_3I laser emission —V. S. Komarov, V. G. Seleznev, and G. A. Skorobogatov. 19(4), 558–60 (Oct. 1974); CPM-7412X0342

Nonlinear polarizability of a gaseous medium in a longitudinal magnetic field —V. A. Sokolov and L. M. Khayutin. 19(5), 589–91 (Nov. 1974); CPM-7501X0383

Infrared nitrogen laser using a transverse discharge —V. F. Tarasenko and Yu. I. Bychkov. 19(5), 693 (Nov. 1974); CPM-7501X0487

Kinetics of gasdynamic lasers. Effect of nozzle geometry on inversion —A. S. Biryukov and L. A. Shelepin. 19(6), 775–81 (Dec. 1974); CPM-7501X0775

N_2O–N_2–He gasdynamic laser —Yu. I. Grin' and V. G. Testov. 19(7), 975 (Jan. 1975); CPM-7503X0863

Plasma dynamic lasers —S. A. Reshetnyak and L. A. Shelepin. 19(8), 1076–80 (Feb. 1975); CPM-7504X1500

Effect of plasma parameters on emission in an ion laser —I. E. Sakharov, V. V. Ermolin, and S. V. Shatalin. 19(8), 1081–4 (Feb. 1975); CPM-7504X1505

Effect of the radiation density on ion drift velocity in a cadmium-helium laser —G. N. Tolmachev, E. L. Latush, and V. S. Mikhalevskii. 19(8), 1120–1 (Feb. 1975); CPM-7504X1544

Absolute-photometry determination of the rate constant of the gas-phase reaction of the radical compound C_3F_7 and $I(^2P_{3/2})$ —G. A. Skorobogatov, V. S. Komarov, and V. G. Seleznev. 19(9), 1239–41 (Mar. 1975); CPM-7505X0661

Effect of a magnetic field on spontaneous mode-locking in a He—Ne laser ($\Lambda = 0.63\mu$) —V. Yu. Petrun'kin, V. M. Nikolaev, O. I. Kotov, and B. V. L'vov. 19(12), 1612–3 (Jun. 1975); CPM-7508X0486

42.60.G Solid lasers

Parasitic amplitude modulation of a stabilized Nd^{3+}:YAG laser —N. M. Galaktionova, A. A. Mak, and A. P. Khyuppenen. 19(4), 486–90 (Oct. 1974); CPM-7412X0270

Pulsed neodymium–glass laser with periodic Q switching —T. A. Kuzovkova, E. V. Nilov, V. A. Rusov, I. N. Semenov, and A. A. Chertkov. 19(4), 503–5 (Oct. 1974); CPM-7412X0287

Frequency–doubling single–mode laser for picosecond pulses —A. M. Bonch–Bruevich, A. M. Tkachuk, and A. A. Fedorov. 19(4), 549–51 (Oct. 1974); CPM-7412X0333

Unidirectional cw oscillation in a solid state ring laser with a return mirror —A. A. Mak, V. I. Ustyugov, V. A. Fromzel', and M. M. Khaleev. 19(4), 552–3 (Oct. 1974); CPM-7412X0336

Spontaneous mode locking in a laser with a multifaceted element —E. I. Kamenskii and V. V. Kozlov. 19(6), 831–2 (Dec. 1974); CPM-7501X0831

Lasing properties of Yb^{3+} and Er^{3+} glass laser pumped by a laser —V. N. Kalinin, A. A. Mak, D. S. Prilezhaev, and V. A. Fromzel'. 19 (6), 835–6 (Dec. 1974); CPM-7501X0835

Solid-state laser with externally forced *Q* switching —N. M. Galaktionova, A. A. Mak, and A. P. Khyuppenen. 19(9), 1174–6 (Mar. 1975); CPM-7505X0596

42.60.J Semiconductor lasers

Time characteristics of the near radiation field of the injection laser —Zh. I. Alferov, V. N. Deryagin, L. E. Marasin, Yu. V. Popov, and E. L. Portnoi. 19(4), 548 (Oct. 1974); CPM-7412X0332

42.60.L Laser resonators, cavities, and modulators

Parasitic amplitude modulation of a stabilized Nd^{3+}:YAG laser —N. M. Galaktionova, A. A. Mak, and A. P. Khyuppenen. 19(4), 486–90 (Oct. 1974); CPM-7412X0270

Polarization of a cavity with a thermally deformed active element —I. B. Vitrishchak, L. N. Soms, and A. A. Tarasov. 19(5), 664–8 (Nov. 1974); CPM-7501X0458

Sign of the change in optical path length in a laser interferometer with feedback —I. M. Belousova and A. F. Zapryagaev. 19(6), 829–30 (Dec. 1974); CPM-7501X0829

Spontaneous mode locking in a laser with a multifaceted element —E. I. Kamenskii and V. V. Kozlov. 19(6), 831–2 (Dec. 1974); CPM-7501X0831

Solid-state laser with externally forced *Q* switching —N. M. Galaktionova, A. A. Mak, and A. P. Khyuppenen. 19(9), 1174–6 (Mar. 1975); CPM-7505X0596

Effect of a magnetic field on spontaneous mode-locking in a He—Ne laser ($\Lambda=0.63\mu$) —V. Yu. Petrun'kin, V. M. Nikolaev, O. I. Kotov, and B. V. L'vov. 19(12), 1612–3 (Jun. 1975); CPM-7508X0486

42.60.N Laser beam interactions and properties

Nonradiative electron transitions and thermal effects in laser–irradiated transparent dielectrics —B. I. Makshantsev, A. A. Kovalev, R. K. Leonov, and P. A. Yampol'skii. 19(1), 98–102 (Jul. 1974); CPM-7407X1610

Optical characteristics of K–8 glass subject to radiation from a neodymium laser —A. M. Bonch–Bruevich, Ya. A. Imas, V. S. Salyadinov, and A. V. Shatilov. 19(2), 287–9 (Aug. 1974); CPM-7408X1551

Quenching in the CF$_3$I photodissociation laser —G. A. Skorobogatov, V. M. Tret'yak, and V. S. Komarov. 19(4), 495–8 (Oct. 1974); CPM-7412X0279

Gas cooling in transmission of high–power CO$_2$ laser radiation through the atmosphere —B. F. Gordiets, A. I. Osipov, and R. V. Khokhlov. 19(5), 669–72 (Nov. 1974); CPM-7501X0463

Nonlinear spherical aberrations and thermoelastic stresses in thermal self–focusing —A. A. Vigasin, Yu. A. Gorokhov, A. P. Sukhorukov, and A. M. Khachatryan. 19(5), 673–5 (Nov. 1974); CPM-7501X0467

Surface evaporation of a solid transparent dielectric under the action of laser radiation —A. M. Bonch-Bruevich, Ya. A. Imas, A. A. Kovalev, P. S. Kondratenko, and B. I. Makshantsev. 19(11), 1474–6 (May 1975); CPM-7506X1228

Interaction of intense laser radiation with solid targets —L. V. Dubovoi, V. D. Dyatlov, V. I. Kryzhanovskii, A. A. Mak, R. N. Medvedev, A. N. Popytaev, V. A. Serebryakov, V. N. Sizov, and A. D. Starikov. 19(11), 1477–9 (May 1975); CPM-7506X1231

Frequency locking in a 3.39μ laser —E. Yu. Andreeva, S. N. Gulyaev, and D. K. Terekhin. 19(12), 1620–1 (Jun. 1975); CPM-7508X0494

Neutral particles from the interaction of laser radiation with a solid target —Yu. A. Bykovskii, N. M. Vasil'ev, I. D. Laptev, and V. N. Nevolin. 19(12), 1635 (Jun. 1975); CPM-7508X0509

42.60.Q Laser beam applications

Effect of focusing conditions on the morphology of surface films produced with a laser —V. G. Dneprovskii and B. A. Osadin. 19 (2), 275–7 (Aug. 1974); CPM-7408X1539

Investigation of spatial distributions in a laser–produced plasma by Hα absorption —G. V. Ostrovskaya and N. A. Pobedonostseva. 19(3), 424–6 (Sep. 1974); CPM-7412X1110

Crystal defects of heterostructures of AlAs–GaAs solid solutions and effect on the characteristics of injection lasers —L. V. Druzhinina, V. T. Bublik, L. M. Dolginov, P. G. Eliseev, M. P. Kerbelev, V. B. Osvenskii, I. Z. Pinsker, and M. G. Shumskii. 19(7), 935–9 (Jan. 1975); CPM-7503X0823

Laser compensation for thermal distortion in optical pumping —V. K. Zaitsev, V. A. Il'inskii, A. M. Marugin, and V. M. Ovchinnikov. 19(11), 1480–1 (May 1975); CPM-7506X1234

42.65.– Nonlinear optics

Second–harmonic generation and emission in wave conversion at a plasma boundary —A. N. Kondratenko, V. G. Shaptala, and V. M. Kuklin. 19(1), 22–4 (Jul. 1974); CPM-7407X1534

Parasitic amplitude modulation of a stabilized Nd^{3+}:YAG laser —N. M. Galaktionova, A. A. Mak, and A. P. Khyuppenen. 19(4), 486–90 (Oct. 1974); CPM-7412X0270

Thermal effect of continuous laser radiation on optically transparent media —N. S. Bardina, A. I. Portnyagin, M. Yu. Sklyarov, and A. A. Churin. 19(4), 491–4 (Oct. 1974); CPM-7412X0275

Reflection of finite amplitude electromagnetic waves from a semiconductor plasma —Yu. F. Filippov. 19(5), 603–6 (Nov. 1974); CPM-7501X0397

Direct and cascade four–photon parametric scattering of light in LiIO$_3$ crystals —S. M. Arakelyan, V. G. Tunkin, A. I. Kholodnykh, and A. S. Chirkin. 19(6), 787–92 (Dec. 1974); CPM-7501X0787

Interaction of intense laser radiation with solid targets —L. V. Dubovoi, V. D. Dyatlov, V. I. Kryzhanovskii, A. A. Mak, R. N. Medvedev, A. N. Popytaev, V. A. Serebryakov, V. N. Sizov, and A. D. Starikov. 19(11), 1477–9 (May 1975); CPM-7506X1231

Transformation of light beams by dynamic correctors using three–dimensional displacement phase holograms —V. G. Sidorovich and D. I. Stasel'ko. 19(12), 1593–7 (Jun. 1975); CPM-7508X0467

Parametric excitation of helicon waves in a plasma by modulated radio frequency waves —V. S. Paverman and D. D. Tskhakya. 19 (12), 1629–30 (Jun. 1975); CPM-7508X0503

42.70.– Optical materials

Nonlinear spherical aberrations and thermoelastic stresses in thermal self–focusing —A. A. Vigasin, Yu. A. Gorokhov, A. P. Sukhorukov, and A. M. Khachatryan. 19(5), 673–5 (Nov. 1974); CPM-7501X0467

42.75.– Optical measurements and instrumentation

Effect of instrumental noise on a system with two spin oscillators using Cs^{133} and He^3 —R. A. Zhitnikov, V. V. Semenov, and P. A. Klyushkin. 19(4), 556–7 (Oct. 1974); CPM-7412X0340

Method for determining the absolute characteristics of CF$_3$I laser emission —V. S. Komarov, V. G. Seleznev, and G. A. Skorobogatov. 19(4), 558–60 (Oct. 1974); CPM-7412X0342

Extraction of synchroton radiation from a cyclic electron accelerator with a strong magnetic field —V. I. Kvochka, V. S. Panasyuk, V. F. Romanovskii, L. N. Samoilov, A. A. Sokolov, B. M. Stepanov, and Yu. M. Tereshkin. 19(6), 762–6 (Dec. 1974); CPM-7501X0762

42.78.– Optical lens and mirror systems

Focusing of an astigmatic beam by a doublet and a symmetric triplet of quadrupole lenses —V. I. Chetvertkov. 19(1), 1–2 (Jul. 1974); CPM-7407X1513

A transaxial lens —V. M. Kel'man, L. M. Nazarenko, and E. M. Yakushev. 19(4), 523–5 (Oct. 1974); CPM-7412X0307

42.80.– Optical devices, techniques, and applications

Round metal–optical waveguide filled with a two–layer dielectric —V. A. Pruzhanovskii. 19(1), 3–8 (Jul. 1974); CPM-7407X1515

Characteristics of diffraction gratings obtained by photoetching of semiconductor surfaces —L. V. Belyakov, D. N. Goryachev, M. N. Mizerov, and E. L. Portnoi. 19(6), 837–8 (Dec. 1974); CPM-7501X0837

42.90.+ Other topics in optics

Strobe unit for measuring luminescence in the range 10^{-7}–$2\cdot10^{-10}$ sec —V. A. Bonch–Bruevich and N. A. Tolstoi. 19(2), 284–6 (Aug. 1974); CPM-7408X1548

43. ACOUSTICS

Magnetoacoustic transducer based on the domain structure of a ferromagnetic material —G. L. Gurevich and G. A. Vul'gal'ter. 19 (1), 154–5 (Jul. 1974); CPM-7407X1666

Optical simulation of a radiator aperture with arbitrary amplitude—phase distribution —M. M. Butusov and Sh. V. Yurevichyus. 19 (6), 833–4 (Dec. 1974); CPM-7501X0833

Thermoacoustic waves in conducting gases and liquids —P. A. Andreev. 19(6), 845–6 (Dec. 1974); CPM-7501X0845

45. FLUID DYNAMICS

45.30.– Turbulence, convection, and heat transfer

Possible use of the schlieren method to measure characteristics of turbulence —V. G. Ivanov. 19(3), 429–31 (Sep. 1974); CPM-7412X1115

Statistical characteristics of the turbulent wake behind a supersonic sphere —V. G. Ivanov, G. I. Mishin, and S. N. Palkin. 19(4), 543–5 (Oct. 1974); CPM-7412X0327

Convection in a liquid dielectric in a longitudinal electric field —I. V. Ioffe and N. V. Kalinin. 19(5), 692 (Nov. 1974); CPM-7501X0486

45.40.– Compressible flows; shock and detonation phenomena

Properties of underexpanded and overexpanded supersonic gas jets —A. V. Antsupov. 19(2), 234–8 (Aug. 1974); CPM-7408X1498

Experimental investigation of microwave radiation produced by hypersonic flows —V. A. Lyutomskii, V. M. Polyakov, and V. G. Testov. 19(4), 483–5 (Oct. 1974); CPM-7412X0267

Statistical characteristics of the turbulent wake behind a supersonic sphere —V. G. Ivanov, G. I. Mishin, and S. N. Palkin. 19(4), 543–5 (Oct. 1974); CPM-7412X0327

Kinetics of gasdynamic lasers. Effect of nozzle geometry on inversion —A. S. Biryukov and L. A. Shelepin. 19(6), 775–81 (Dec. 1974); CPM-7501X0775

Propagation of shock waves in inhomogeneous media —R. A. Glatman. 19(11), 1390–2 (May 1975); CPM-7506X1144

Theory of nonequilibrium shock waves —R. A. Glatman and I. V. Ioffe. 19(11), 1482–3 (May 1975); CPM-7506X1236

45.45.– Rarefied gas dynamics

Condensation of a dense vapor flow —V. G. Dneprovskii, B. A. Osadin, and N. V. Rusakov. 19(2), 271–4 (Aug. 1974); CPM-7408X1535

Use of the distribution function to describe free molecular beams —I. G. Neudachin, B. T. Porodnov, and P. E. Suetin. 19(4), 511–4 (Oct. 1974); CPM-7412X0295

Flow of low–density gases in a capillary grid —B. T. Porodnov, V. D. Akin'shin, V. I. Kichaev, S. F. Borisov, and P. E. Suetin. 19(4), 515–8 (Oct. 1974); CPM-7412X0299

Composition of adsorbing and desorbing fluxes —Yu. A. Gel'man, V. I. Mikhailov, V. F. Vinogradov, and Yu. N. Lyubitov. 19(10), 1355–8 (Apr. 1975); CPM-7506X0289

45.50.– External flows, waves, instabilities, and cavitation

Properties of underexpanded and overexpanded supersonic gas jets —A. V. Antsupov. 19(2), 234–8 (Aug. 1974); CPM-7408X1498

Statistical characteristics of the turbulent wake behind a supersonic sphere —V. G. Ivanov, G. I. Mishin, and S. N. Palkin. 19(4), 543–5 (Oct. 1974); CPM-7412X0327

Local–potential study of the Bénard problem in a homogeneous magnetic field —A. I. Lopushanskaya and V. N. Kapranov. 19(5), 612–4 (Nov. 1974); CPM-7501X0406

Current–driven instability in a conducting fluid —A. M. Kovnatskii. 19(5), 691 (Nov. 1974); CPM-7501X0485

Formation of a narrow gas jet in vacuum —G. I. Dimov and V. Ya. Savkin. 19(6), 755–8 (Dec. 1974); CPM-7501X0755

Photochemical waves in a medium with a branch–chain conversion mechanism —A. N. Oraevskii, V. P. Pimenov, and V. A. Shcheglov. 19(6), 782–6 (Dec. 1974); CPM-7501X0782

Free expansion of plasma jets —P. A. Demchenko, L. I. Krupnik, and E. S. Lyangner. 19(11), 1426–8 (May 1975); CPM-7506X1180

45.55.+ Conducting fluids, magnetohydrodynamics, and electrohydrodynamics

Stabilization of MHD instabilities by a high–frequency current in a straight system —V. P. Fedyakova. 19(1), 16–9 (Jul. 1974); CPM-7407X1528

Radiating discharges confined by walls —A. F. Aleksandrov, I. S. Marshak, and A. A. Rukhadze. 19(3), 308–14 (Sep. 1974); CPM-7412X0994

Local–potential study of the Bénard problem in a homogeneous magnetic field —A. I. Lopushanskaya and V. N. Kapranov. 19(5), 612–4 (Nov. 1974); CPM-7501X0406

Possible electrohydrodynamic effects in electrolytes —E. Z. Gak, É. Kh. Rokhinson, and N. F. Bondarenko. 19(5), 676–7 (Nov. 1974); CPM-7501X0470

Current–driven instability in a conducting fluid —A. M. Kovnatskii. 19(5), 691 (Nov. 1974); CPM-7501X0485

Magnetohydrodynamic channel flow in a tapered magnetic field —S. A. Regirer. 19(7), 874–7 (Jan. 1975); CPM-7503X0762

Nonstationary magnetohydrodynamic flow and wave propagation —M. Ya. Antimirov and Yu. Ya. Boguslavskii. 19(7), 878–9 (Jan. 1975); CPM-7503X0766

45.65.– Nonhomogeneous flows

Measurement of statistical parameters of scattering particles in laminar flow by Doppler spectroscopy —A. P. Ivanov, A. Ya. Khairullina, and A. P. Chaikovski. 19(2), 267–70 (Aug. 1974); CPM-7408X1531

Condensation of a dense vapor flow —V. G. Dneprovskii, B. A. Osadin, and N. V. Rusakov. 19(2), 271–4 (Aug. 1974); CPM-7408X1535

Thermophoresis and diffusophoresis of small, volatile aerosol particles —Yu. I. Yalamov and E. R. Shchukin. 19(2), 278–9 (Aug. 1974); CPM-7408X1542

Motion of stable aerosol particles —O. A. Barsegyan and Yu. I. Yalamov. 19(11), 1486–7 (May 1975); CPM-7506X1240

45.80.+ Fluid-dynamic measurements and instrumentation

Measurement of statistical parameters of scattering particles in laminar flow by Doppler spectroscopy —A. P. Ivanov, A. Ya. Khairullina, and A. P. Chaikovski. 19(2), 267–70 (Aug. 1974); CPM-7408X1531

Possible use of the schlieren method to measure characteristics of turbulence —V. G. Ivanov. 19(3), 429–31 (Sep. 1974); CPM-7412X1115

Use of a field-emission microscope to measure the pressure of pump oil —V. Ya. Pliskovskii, M. S. Sukonnik, and V. A. Shishkin. 19 (10), 1347–51 (Apr. 1975); CPM-7506X0281

45.90.+ Other topics in fluid dynamics

Gas–kinetic removal of neutral molecules from an ion beam —V. P. Ivanov. 19(2), 239–42 (Aug. 1974); CPM-7408X1503

Measurement of statistical parameters of scattering particles in laminar flow by Doppler spectroscopy —A. P. Ivanov, A. Ya. Khairullina, and A. P. Chaikovski. 19(2), 267–70 (Aug. 1974); CPM-7408X1531

Radiating discharges confined by walls —A. F. Aleksandrov, I. S. Marshak, and A. A. Rukhadze. 19(3), 308–14 (Sep. 1974); CPM-7412X0994

Kinetics of gasdynamic lasers. Effect of nozzle geometry on inversion —A. S. Biryukov and L. A. Shelepin. 19(6), 775–81 (Dec. 1974); CPM-7501X0775

State of a gas moving near a solid surface —S. P. Bakanov and B. M. Markeev. 19(10), 1293–4 (Apr. 1975); CPM-7506X0227

51. THE PHYSICS OF FLUIDS

51.20.+ Viscosity and diffusion, experimental

Temperature dependence of trace diffusion coefficients of certain gases —A. É. Loiko, B. A. Ivakin, and P. E. Suetin. 19(3), 434 (Sep. 1974); CPM-7412X1120

Plasma diffusion in the Tornado device —A. N. Kozyrev and B. P. Peregud. 19(4), 468–74 (Oct. 1974); CPM-7412X0252

Steady-state study of the temperature dependence of the mutual–diffusion coefficients of certain gases —N. D. Kosov and B. P. Solonitsyn. 19(4), 541–2 (Oct. 1974); CPM-7412X0325

Thermal diffusion in a mixture of cesium vapor and helium —E. S. Bekmukhambetov and V. A. Donov. 19(12), 1627–8 (Jun. 1975); CPM-7508X0501

51.30.+ Thermal properties of gases

Gas cooling in transmission of high–power CO_2 laser radiation through the atmosphere —B. F. Gordiets, A. I. Osipov, and R. V. Khokhlov. 19(5), 669–72 (Nov. 1974); CPM-7501X0463

Gas temperature in the positive column of a medium-β helium discharge —Yu. M. Kagan and K. K. Paskalev. 19(12), 1601–3 (Jun. 1975); CPM-7508X0475

Temperature and electron density in the positive column of a medium-pressure helium discharge —Yu. M. Kagan and K. K. Paskalev. 19(12), 1604–5 (Jun. 1975); CPM-7508X0478

51.50.+ Electrical phenomena in gases

Extrapolation of the Langmuir S–curve to cesium pressures of 10–100 torr —V. E. Dubinskii and S. Ya. Lebedev. 19(1), 81–3 (Jul. 1974); CPM-7407X1593

Ionization of a gas–discharge gap by fast electrons —O. B. Evdokimov and A. P. Yalovets. 19(1), 138–9 (Jul. 1974); CPM-7407X1650

Production of an ion beam by a magnetic system with opposed fields —V. B. Glasko, A. G. Sveshnikov, and N. N. Semashko. 19(2), 201–5 (Aug. 1974); CPM-7408X1465

Physical properties of an electrodeless pulsed discharge in a gas–filled glass cell —Yu. I. Chutov, N. S. Baranchuk, M. R. Lozovich, and V. G. Danilov. 19(2), 224–8 (Aug. 1974); CPM-7408X1488

Fast electrons and x rays from nanosecond gas discharges at 0.1–760 torr —L. V. Tarasova, L. N. Khudyakova, T. V. Loiko, and V. A. Tsukerman. 19(3), 351–3 (Sep. 1974); CPM-7412X1037

Electron energy distribution in helium, nitrogen, and their mixtures —K. D. Asvadurov, I. A. Vasil'eva, and V. M. Torchinskii. 19(3), 354–7 (Sep. 1974); CPM-7412X1040

Stability of field–emission beams in nonsecond discharges —L. P. Babich. 19(3), 371–2 (Sep. 1974); CPM-7412X1057

Transmission of a high–current relativistic beam through a gas —Yu. V. Tkach, I. I. Magda, G. V. Skachek, S. S. Pushkarev, and I. P. Panchenko. 19(3), 412–3 (Sep. 1974); CPM-7412X1098

Optical radiation from nanosecond discharges in dense gases —L. P. Babich. 19(3), 419–20 (Sep. 1974); CPM-7412X1105

Nonlinear polarizability of a gaseous medium in a longitudinal magnetic field —V. A. Sokolov and L. M. Khayutin. 19(5), 589–91 (Nov. 1974); CPM-7501X0383

Stability of ball lightning —I. P. Stakhanov. 19(7), 861–4 (Jan. 1975); CPM-7503X0749

High–frequency discharge in a mercury—helium mixture —S. D. Vagner, Yu. M. Kagan, A. I. Konstantinov, and I. S. Niskonen. 19 (7), 898–900 (Jan. 1975); CPM-7503X0786

Effect of loss on electron avalanches in optical breakdown —V. I. Fisher. 19(8), 1050–2 (Feb. 1975); CPM-7504X1474

Dielectric strength of spark gaps following strong current pulses —E. P. Bel'kov. 19(9), 1210–3 (Mar. 1975); CPM-7505X0632

Effects due to streamer shape —É. D. Lozanskii and D. B. Pontekorvo. 19(11), 1432–3 (May 1975); CPM-7506X1186

Loss of neutralization for a stable neutralized ion beam —M. D. Gabovich. 19(11), 1502–3 (May 1975); CPM-7506X1256

Gas temperature in the positive column of a medium-β helium discharge —Yu. M. Kagan and K. K. Paskalev. 19(12), 1601–3 (Jun. 1975); CPM-7508X0475

Temperature and electron density in the positive column of a medium-pressure helium discharge —Yu. M. Kagan and K. K. Paskalev. 19(12), 1604–5 (Jun. 1975); CPM-7508X0478

Electrical strength of nitrogen and hyrodgen at high pressures —É. A. Avilov and N. V. Belkin. 19(12), 1631–2 (Jun. 1975); CPM-7508X0505

51.90.+ Other topics in the physics of fluids

Gas focusing of a negative–ion beam —M. D. Gabovich, A. P. Naida, I. M. Protsenko, L. S. Simonenko, and I. A. Soloshenko. 19(4), 546–7 (Oct. 1974); CPM-7412X0330

Photochemical waves in a medium with a branch–chain conversion mechanism —A. N. Oraevskii, V. P. Pimenov, and V. A. Shcheglov. 19(6), 782–6 (Dec. 1974); CPM-7501X0782

Thermoacoustic waves in conducting gases and liquids —P. A. Andreev. 19(6), 845–6 (Dec. 1974); CPM-7501X0845

Viscous momentum transport in a gaseous mixture —B. M. Markeev. 19(7), 969–70 (Jan. 1975); CPM-7503X0857

State of a gas moving near a solid surface —S. P. Bakanov and B. M. Markeev. 19(10), 1293–4 (Apr. 1975); CPM-7506X0227

Measurement of transverse relaxation time T_2 of optically oriented He^4 with an oscillator magnetometer–N. A. Dovator, R. A. Zhitnikov, and P. P. Kuleshov. 19(12), 1608–9 (Jun. 1975); CPM-7508X0482

52. THE PHYSICS OF PLASMAS AND ELECTRIC DISCHARGES

52.20.- Elementary processes in plasma

Expansion of a recombining plasma in vacuum —E. E. Lovetskii, A. N. Polyanichev, and V. S. Fetisov. 19(5), 647–50 (Nov. 1974); CPM-7501X0441

Effect of a high–frequency electric field on the energy loss of a charged particle in a medium —Zh. M. Diasamidze. 19(5), 687–8 (Nov. 1974); CPM-7501X0481

Conversion of neutral hydrogen into protons in dense plasmas —T. A. Bazilevskaya, L. I. Krupnik, and N. G. Shulika. 19(6), 741–4 (Dec. 1974); CPM-7501X0741

Acceleration of plasma electrons in strong electric fields —Z. A. Al'bikov, M. I. Ivanov, V. I. Kazacha, O. V. Kozlov, V. D. Rusanov, and S. S. Sobolev. 19(11), 1498–9 (May 1975); CPM-7506X1252

Loss of neutralization for a stable neutralized ion beam —M. D. Gabovich. 19(11), 1502–3 (May 1975); CPM-7506X1256

52.25.- Plasma basic properties

52.25.D Plasma kinetic equations

Recombination in an expanding plasma —Yu. A. Bykovskii, N. N. Degtyarenko, V. F. Elesin, V. E. Kondrashov, E. E. Lovetskii, A. N. Polyanichev, and V. S. Fetisov. 19(1), 43–8 (Jul. 1974); CPM-7407X1555

Microwave discharge in argon —E. V. Belousov, A. S. Bryukhovetskii, and A. V. Prokopov. 19(1), 53–6 (Jul. 1974); CPM-7407X1565

Symmetry of high–frequency plasma motions —A. A. Zhmudskii and V. B. Taranov. 19(6), 717–8 (Dec. 1974); CPM-7501X0717

Linear transient response of a fully ionized plasma in a pulsed electric field —V. V. Istomin, S. P. Sher, and S. P. Dovgopol. 19(7), 963–4 (Jan. 1975); CPM-7503X0851

Energy of charged particles accelerated by electromagnetic waves in a plasma with a spatially decreasing density —V. Ya. Davydovskii and A. S. Ukolov. 19(10), 1303–7 (Apr. 1975); CPM-7506X0237

Anisotropic plasma heating near the lower hybrid frequency —V. M. Glagolev, V. V. Martynenko, and Yu. V. Skosyrev. 19(12), 1543–6 (Jun. 1975); CPM-7508X0417

52.25.F Transport properties

Conductivity of a medium with inhomogeneous inclusions in a magnetic field —Yu. P. Emets. 19(5), 586–8 (Nov. 1974); CPM-7501X0380

Ion-acoustic instability of a fully ionized ultrarelativistic plasma in an electric field —D. I. Dzhavakhishvili. 19(7), 959–60 (Jan. 1975); CPM-7503X0847

Power spectrum of potential fluctuations in a moving magnetoactive plasma —V. M. Kostin. 19(8), 1053–6 (Feb. 1975); CPM-7504X1477

Measurement of ion density by the dispersion relation for an ion-beam plasma —M. D. Gabovich, L. P. Katsubo, and I. A. Soloshenko. 19(11), 1412–3 (May 1975); CPM-7506X1166

Anomalous resistivity of transverse plasma current at electron-cyclotron harmonics —V. I. Aref'ev and A. A. Chernov. 19(12), 1522–8 (Jun. 1975); CPM-7508X0396

52.25.G Fluctuation phenomena

Linear theory for the low-frequency electromagnetic properties of an isotropic turbulent plasma —K. Komilov, F. Kh. Khakimov, and V. N. Tsytovich. 19(5), 615–7 (Nov. 1974); CPM-7501X0409

52.25.K Thermodynamics of plasmas

Measurement of plasma electron temperature with a sinusoidal probe potential —B. I. Kanaev, V. V. Piterskii, and E. E. Yushmanov. 19 (11), 1421–3 (May 1975); CPM-7506X1175

52.25.M Dielectric properties

Dielectric breakdown of detonation products —V. L. Korol'kov, M. A. Mel'nikov, and A. P. Tsyplenko. 19(12), 1569–70 (Jun. 1975); CPM-7508X0443

52.25.P Emission, absorption, and scattering of radiation

Emission of waves from a plasma layer —T. A. Davydova and A. A. Zhmudskii. 19(1), 12–5 (Jul. 1974); CPM-7407X1524

Second-harmonic generation and emission in wave conversion at a plasma boundary —A. N. Kondratenko, V. G. Shaptala, and V. M. Kuklin. 19(1), 22–4 (Jul. 1974); CPM-7407X1534

Conversion of an electromagnetic wave into an ion-acoustic wave in an inhomogeneous plasma —A. N. Kondratenko and V. M. Kuklin. 19(1), 25–7 (Jul. 1974); CPM-7407X1537

Reflecting properties of an inhomogeneous anisotropic plasma layer —V. A. Zhivulin and G. I. Makarov. 19(1), 123 (Jul. 1974); CPM-7407X1635

Kinetic theory for wave reflection from a moving plasma —Yu. V. Bogomolov. 19(2), 190–2 (Aug. 1974); CPM-7408X1454

Scattering of high-frequency electromagnetic waves by ion-acoustic oscillations in a bounded plasma —V. G. Shaptala. 19(2), 193–6 (Aug. 1974); CPM-7408X1457

Role of collisions in plasma absorption of electromagnetic waves near the lower hybrid —B. V. Galaktionov, V. V. D'yachenko, M. M. Larionov, and O. N. Shcherbinin. 19(4), 459–62 (Oct. 1974); CPM-7412X0243

Experimental investigation of microwave radiation produced by hypersonic flows —V. A. Lyutomskii, V. M. Polyakov, and V. G. Testov. 19(4), 483–5 (Oct. 1974); CPM-7412X0267

Evolution of monochromatic whistler and plasma-wave packets in a collisionless plasma —Ya. N. Istomin. 19(4), 529–30 (Oct. 1974); CPM-7412X0313

Reflection of electromagnetic waves by a moving plasma —V. I. Miroshnichenko. 19(4), 533–4 (Oct. 1974); CPM-7412X0317

Reflection of finite amplitude electromagnetic waves from a semiconductor plasma —Yu. F. Filippov. 19(5), 603–6 (Nov. 1974); CPM-7501X0397

Impossibility of shielding against the rf radiation of a thermonuclear reactor with a cold-plasma sheath —A. S. Chikhachev. 19(5), 685 (Nov. 1974); CPM-7501X0479

Generation of drift waves by an rf field near the lower hybrid frequency —Yu. F. Baranov, D. G. Bulyginskii, M. I. Vil'dzhyunas, B. V. Galaktionov, and N. V. Shustova. 19(6), 732–5 (Dec. 1974); CPM-7501X0732

Electromagnetic fields outside a synthesized plasma jet —E. V. Bogdanov, G. M. Mantrova, and M. N. Yakovleva. 19(7), 919–21 (Jan. 1975); CPM-7503X0807

Radio-frequency absorption in a plasma confined by rf plugs —K. S. Golovanivskii, V. D. Dougar-Jabon, and L. A. Pokhmel'nykh. 19 (11), 1484–5 (May 1975); CPM-7506X1238

Rotation of Poynting vector for ultralow-frequency ion waves in an inhomogeneous plasma —Ya. L. Al'pert and R. N. Kaufman. 19 (12), 1519–21 (Jun. 1975); CPM-7508X0393

Anomalous ion heating in a parametrically unstable plasma —I. S. Baikov and V. P. Silin. 19(12), 1529–33 (Jun. 1975); CPM-7508X0403

52.30.+ Plasma flow; magnetohydrodynamics

Stability of field-emission beams in nonsecond discharges —L. P. Babich. 19(3), 371–2 (Sep. 1974); CPM-7412X1057

Plasma diffusion in the Tornado device —A. N. Kozyrev and B. P. Peregud. 19(4), 468–74 (Oct. 1974); CPM-7412X0252

Supersonic plasma jet from a high-power pulsed discharge —M. A. Sultanov. 19(4), 478–82 (Oct. 1974); CPM-7412X0262

Cerenkov instabilities of a relativistic beam in a periodic plasma-filled waveguide —V. I. Kurilko, Yu. V. Tkach, and V. A. Shendrik. 19 (5), 607–11 (Nov. 1974); CPM-7501X0401

Coaxial plasma injector with programmed injection —V. A. Burtsev, V. N. Litunovskii, and M. P. Nadgornaya. 19(6), 736–40 (Dec. 1974); CPM-7501X0736

Magnetohydrodynamic channel flow in a tapered magnetic field —S. A. Regirer. 19(7), 874–7 (Jan. 1975); CPM-7503X0762

Nonstationary magnetohydrodynamic flow and wave propagation —M. Ya. Antimirov and Yu. Ya. Boguslavskii. 19(7), 878–9 (Jan. 1975); CPM-7503X0766

Lagrange problem in magnetohydrodynamics —P. V. Zagorskii and Yu. P. Lun'kin. 19(8), 1009–11 (Feb. 1975); CPM-7504X1433

Magnetohydrodynamic stability of a neutral current layer in a plasma —S. V. Bulanov. 19(9), 1246–7 (Mar. 1975); CPM-7505X0668

Free expansion of plasma jets —P. A. Demchenko, L. I. Krupnik, and E. S. Lyangner. 19(11), 1426–8 (May 1975); CPM-7506X1180

Analysis of magnetic deflection systems —O. M. Vovk and O. Ya. Popov. 19(11), 1504 (May 1975); CPM-7506X1258

Two-stream flow in a thin plasma slab —A. V. Pashchenko and B. N. Rutkevich. 19(12), 1538–40 (Jun. 1975); CPM-7508X0412

Formation of a plasma focus in a plasma erosion accelerator. II. Energy characteristics of the dense plasma focus —N. P. Kozlov, L. V. Leskov, Yu. S. Protasov, and V. I. Khvesyuk. 19(12), 1558–9 (Jun. 1975); CPM-7508X0432

Hot probe measurements in a rarefied streaming plasma —E. M. Netsvetailov, L. V. Nosachev, and V. V. Skvortsov. 19(12), 1579–83 (Jun. 1975); CPM-7508X0453

52.35.– Waves, oscillations, and instabilities in plasma

Kinetic plasma instabilities excited by a monoenergetic beam —A. I. Ranyuk and V. L. Sizonenko. 19(5), 628–9 (Nov. 1974); CPM-7501X0422

Instabilities in a finite-β plasma with transverse current. I —A. I. Pyatak and V. L. Sizonenko. 19(5), 635–9 (Nov. 1974); CPM-7501X0429

Instabilities in a finite-β plasma with transverse current. II —A. I. Pyatak and V. L. Sizonenko. 19(5), 640–4 (Nov. 1974); CPM-7501X0434

Generation of drift waves by an rf field near the lower hybrid frequency —Yu. F. Baranov, D. G. Bulyginskii, M. I. Vil'dzhyunas, B. V. Galaktionov, and N. V. Shustova. 19(6), 732–5 (Dec. 1974); CPM-7501X0732

52.35.C Linear waves and oscillations

Excitation of Alfvén waves in decay instabilities —A. G. Elfimov and F. M. Nekrasov. 19(1), 9–11 (Jul. 1974); CPM-7407X1521

Emission of waves from a plasma layer —T. A. Davydova and A. A. Zhmudskii. 19(1), 12–5 (Jul. 1974); CPM-7407X1524

Stabilization of MHD instabilities by a high-frequency current in a straight system —V. P. Fedyakova. 19(1), 16–9 (Jul. 1974); CPM-7407X1528

Nonmonoenergetic relativistic electron beam in a bounded collisional plasma —V. P. Grigor'ev and N. S. Shulaev. 19(1), 20–1 (Jul. 1974); CPM-7407X1532

Conversion of an electromagnetic wave into an ion-acoustic wave in an inhomogeneous plasma —A. N. Kondratenko and V. M. Kuklin. 19(1), 25–7 (Jul. 1974); CPM-7407X1537

Nonlinear plasma waves and ion–acoustic waves in an isotropic plasma —V. Sh. Livadonov and S. M. Fainshtein. 19(1), 28–30 (Jul. 1974); CPM-7407X1540
Ionization discontinuity in large–amplitude striations —A. V. Nedospasov and V. G. Petrov. 19(1), 31–4 (Jul. 1974); CPM-7407X1543
Longitudinal oscillations in an ultrarelativistic electron plasma —D. I. Dzhavakhishvili. 19(1), 115 (Jul. 1974); CPM-7407X1627
Effect of cathode emission on the threshold for striations —N. A. Vorob'eva, Yu. M. Kagan, V. M. Milenin, and A. Kh. Muradov. 19(1), 117–8 (Jul. 1974); CPM-7407X1629
Ionization oscillations in a plasma in the presence of ionizing radiation —B. V. Vainer. 19(1), 119–20 (Jul. 1974); CPM-7407X1631
Parametric plasma instabilities excited by the sudden application of an electric field —A. B. Kitsenko and K. N. Stepanov. 19(1), 127–8 (Jul. 1974); CPM-7407X1639
Generation of Bernstein modes in beam–plasma system —V. N. Fedorenko. 19(2), 171–4 (Aug. 1974); CPM-7408X1435
Excitation of electromagnetic ion cyclotron waves by fast ions —T. D. Kaladze, D. G. Lominadze, and K. N. Stepanov. 19(2), 175–6 (Aug. 1974); CPM-7408X1439
Parametric instability of an electron beam in a magnetic field —A. I. Pasynok and N. S. Repalov. 19(2), 177–80 (Aug. 1974); CPM-7408X1441
Scattering by ion–acoustic waves in a rectangular waveguide —S. V. Troitskii. 19(2), 181–4 (Aug. 1974); CPM-7408X1445
Scattering of high–frequency electromagnetic waves by ion–acoustic oscillations in a bounded plasma —V. G. Shaptala. 19(2), 193–6 (Aug. 1974); CPM-7408X1457
Surface waves in a magnetized plasma in a radio–frequency field —E. E. Lovetskii and A. N. Starodub. 19(3), 319–22 (Sep. 1974); CPM-7412X1005
Damping of ion–acoustic waves in a bounded plasma —A. N. Kondratenko and V. M. Kuklin. 19(3), 326–8 (Sep. 1974); CPM-7412X1012
Nonlinear instability of a helicon packet in an anisotropic plasma —Ya. N. Istomin and V. I. Karpman. 19(3), 405–6 (Sep. 1974); CPM-7412X1091
Long–wave cyclotron instability in a plasma in an inhomogeneous magnetic field —A. S. Kukushkin. 19(3), 410–1 (Sep. 1974); CPM-7412X1096
Linear theory for the low–frequency electromagnetic properties of an isotropic turbulent plasma —K. Komilov, F. Kh. Khakimov, and V. N. Tsytovich. 19(5), 615–7 (Nov. 1974); CPM-7501X0409
Excitation of surface electromagnetic waves in a plasma cylinder surrounded by a hollow electron beam —O. V. Dolzhenko, A. V. Zosimov, and A. A. Rukhadze. 19(5), 618–21 (Nov. 1974); CPM-7501X0412
Quasilinear theory of beam–generated surface waves in a plasma —V. I. Pakhomov and V. L. Sizonenko. 19(5), 630–4 (Nov. 1974); CPM-7501X0424
Absolute decay instability of low–frequency waves in an inhomogeneous plasma —A. D. Piliya and V. I. Fedorov. 19(5), 686 (Nov. 1974); CPM-7501X0480
Current–driven instability in a conducting fluid —A. M. Kovnatskii. 19(5), 691 (Nov. 1974); CPM-7501X0485
Symmetry of high–frequency plasma motions —A. A. Zhmudskii and V. B. Taranov. 19(6), 717–8 (Dec. 1974); CPM-7501X0717
Magnetodrift waves in a finite–β plasma —N. M. Ryzhov, V. L. Sizonenko, V. A. Suprunenko, E. A. Sukhomlin, and Yu. V. Gutarev. 19(6), 722–5 (Dec. 1974); CPM-7501X0722
Nonstationary magnetohydrodynamic flow and wave propagation —M. Ya. Antimirov and Yu. Ya. Boguslavskii. 19(7), 878–9 (Jan. 1975); CPM-7503X0766
Surface waves in periodic plasma systems —V. F. Dryakhlushin and Yu. A. Romanov. 19(7), 883–6 (Jan. 1975); CPM-7503X0771
Solitary waves in anisotropic plasma waveguide —V. I. Kurilko and A. P. Tolstoluzhskii. 19(7), 887–90 (Jan. 1975); CPM-7503X0775
Low–frequency oscillations in counter–streaming high–current electron beams —A. F. Timoshenko, D. V. Iremashvili, and Yu. K. Udovichenko. 19(8), 1038–41 (Feb. 1975); CPM-7504X1462
Power spectrum of potential fluctuations in a moving magnetoactive plasma —V. M. Kostin. 19(8), 1053–6 (Feb. 1975); CPM-7504X1477
Stochastic acceleration of electrons in nanosecond discharges —L. P. Babich. 19(9), 1154–6 (Mar. 1975); CPM-7505X0576
Modulation of microwaves by density fluctuations in a plasma —L. A. Dushin, A. V. Serikov, A. I. Skibenko, E. V. Krivorukov, and I. P. Fomin. 19(9), 1163–7 (Mar. 1975); CPM-7505X0585
Wave excitation at half the gyrofrequency in counterstreaming electron beams —A. P. Timoshenko, D. V. Iremashvili, and Yu. K. Udovichenko. 19(12), 1584–6 (Jun. 1975); CPM-7508X0458

52.35.E Plasma instabilities

Parametric instability of a spatially moderated electron beam in a magnetic field —N. S. Repalov and V. F. Tyrnov. 19(7), 871–3 (Jan. 1975); CPM-7503X0759
Ion–acoustic instability of a fully ionized ultrarelativistic plasma in an electric field —D. I. Dzhavakhishvili. 19(7), 959–60 (Jan. 1975); CPM-7503X0847
Hydrodynamic stability of the Uragan stellarator —V. M. Zalkind, Yu. K. Kuznetsov, V. K. Pashnev, and V. M. Tonkopryad. 19(8), 1123–5 (Feb. 1975); CPM-7504X1547
Transverse-current plasma instability —D. G. Lominadze and V. L. Sizonenko. 19(9), 1145–9 (Mar. 1975); CPM-7505X0567
Plasma instability due to an anisotropic electron distribution —D. G. Lominadze and V. L. Sizonenko. 19(9), 1150–3 (Mar. 1975); CPM-7505X0572
High-frequency instabilities in an inhomogeneous, anisotropic finite-β plasma —V. D. Egorenkov and A. I. Pyatak. 19(9), 1160–2 (Mar. 1975); CPM-7505X0582
Magnetohydrodynamic stability of a neutral current layer in a plasma —S. V. Bulanov. 19(9), 1246–7 (Mar. 1975); CPM-7505X0668
Ion energy spectra and collective effects in a Penning ion source —V. I. Farenik, V. V. Vlasov, A. M. Rozhkov, and A. A. Kozharin. 19 (9), 1258–9 (Mar. 1975); CPM-7505X0680
Turbulent plasma heating and the Buneman instability —V. L. Sizonenko. 19(9), 1260–1 (Mar. 1975); CPM-7505X0682
Drift instability in a weakly ionized plasma —S. V. Putvinskii and A. V. Timofeev. 19(10), 1295–9 (Apr. 1975); CPM-7506X0229
Nonlinear effects for the "kink" instability in an electron-ion ring —G. P. Berman. 19(10), 1312–6 (Apr. 1975); CPM-7506X0246
Instabilities in interpenetrating electron and ion beams —I. A. Soloshenko and L. P. Katsubo. 19(10), 1317–20 (Apr. 1975); CPM-7506X0251
Mechanism for plasma loss from a magnetic trap —V. I. Volosov. 19 (11), 1408–11 (May 1975); CPM-7506X1162
Stabilization of two-stream instabilities —V. A. Buts. 19(11), 1496–7 (May 1975); CPM-7506X1250
Low-frequency helical instability in a high-frequency electric field —V. S. Paverman and D. D. Tskhakaya. 19(11), 1508–9 (May 1975); CPM-7506X1262
Anomalous resistivity of transverse plasma current at electron-cyclotron harmonics —V. I. Aref'ev and A. A. Chernov. 19(12), 1522–8 (Jun. 1975); CPM-7508X0396
Interaction of a hollow electron beam with a plasma —N. M. Zemlyanskii, A. K. Berezin, Ya. B. Fainberg, L. I. Bolotin, and S. S. Krivulya. 19(12), 1547–8 (Jun. 1975); CPM-7508X0421
Current-convective instability in a three-component plasma —E. Z. Meilikhov. 19(12), 1610–1 (Jun. 1975); CPM-7508X0484
Connection of magnetic lines of force in a neutral layer —A. T. Altyntsev and V. I. Krasov. 19(12), 1639–40 (Jun. 1975); CPM-7508X0513

52.35.G Nonlinear waves and nonlinear interactions

Excitation of Alfvén waves in decay instabilities —A. G. Elfimov and F. M. Nekrasov. 19(1), 9–11 (Jul. 1974); CPM-7407X1521
Emission of waves from a plasma layer —T. A. Davydova and A. A. Zhmudskii. 19(1), 12–5 (Jul. 1974); CPM-7407X1524
Stabilization of MHD instabilities by a high–frequency current in a straight system —V. P. Fedyakova. 19(1), 16–9 (Jul. 1974); CPM-7407X1528
Nonmonoenergetic relativistic electron beam in a bounded collisional plasma —V. P. Grigor'ev and N. S. Shulaev. 19(1), 20–1 (Jul. 1974); CPM-7407X1532
Conversion of an electromagnetic wave into an ion–acoustic wave in an inhomogeneous plasma —A. N. Kondratenko and V. M. Kuklin. 19(1), 25–7 (Jul. 1974); CPM-7407X1537
Nonlinear plasma waves and ion–acoustic waves in an isotropic plasma —V. Sh. Livadonov and S. M. Fainshtein. 19(1), 28–30 (Jul. 1974); CPM-7407X1540
Ionization discontinuity in large–amplitude striations —A. V. Nedospasov and V. G. Petrov. 19(1), 31–4 (Jul. 1974); CPM-7407X1543

Longitudinal oscillations in an ultrarelativistic electron plasma —D. I. Dzhavakhishvili. 19(1), 115 (Jul. 1974); CPM-7407X1627

Effect of cathode emission on the threshold for striations —N. A. Vorob'eva, Yu. M. Kagan, V. M. Milenin, and A. Kh. Muradov. 19(1), 117–8 (Jul. 1974); CPM-7407X1629

Ionization oscillations in a plasma in the presence of ionizing radiation —B. V. Vainer. 19(1), 119–20 (Jul. 1974); CPM-7407X1631

Parametric plasma instabilities excited by the sudden application of an electric field —A. B. Kitsenko and K. N. Stepanov. 19(1), 127–8 (Jul. 1974); CPM-7407X1639

Generation of Bernstein modes in beam–plasma system —V. N. Fedorenko. 19(2), 171–4 (Aug. 1974); CPM-7408X1435

Excitation of electromagnetic ion cyclotron waves by fast ions —T. D. Kaladze, D. G. Lominadze, and K. N. Stepanov. 19(2), 175–6 (Aug. 1974); CPM-7408X1439

Parametric instability of an electron beam in a magnetic field —A. I. Pasynok and N. S. Repalov. 19(2), 177–80 (Aug. 1974); CPM-7408X1441

Scattering by ion–acoustic waves in a rectangular waveguide —S. V. Troitskii. 19(2), 181–4 (Aug. 1974); CPM-7408X1445

Multimode parametric interactions in a plasma with low–frequency pumping —Yu. M. Sorokin and N. S. Stepanov. 19(2), 185–9 (Aug. 1974); CPM-7408X1449

Scattering of high–frequency electromagnetic waves by ion–acoustic oscillations in a bounded plasma —V. G. Shaptala. 19(2), 193–6 (Aug. 1974); CPM-7408X1457

Surface waves in a magnetized plasma in a radio–frequency field —E. E. Lovetskii and A. N. Starodub. 19(3), 319–22 (Sep. 1974); CPM-7412X1005

Damping of ion–acoustic waves in a bounded plasma —A. N. Kondratenko and V. M. Kuklin. 19(3), 326–8 (Sep. 1974); CPM-7412X1012

Nonlinear instability of a helicon packet in an anisotropic plasma —Ya. N. Istomin and V. I. Karpman. 19(3), 405–6 (Sep. 1974); CPM-7412X1091

Long–wave cyclotron instability in a plasma in an inhomogeneous magnetic field —A. S. Kukushkin. 19(3), 410–1 (Sep. 1974); CPM-7412X1096

Launching and propagation of regular nonlinear waves in an anisotropic plasma–filled waveguide —V. I. Kurilko, A. P. Tols–toluzhskii, and Ya. B. Fainberg. 19(5), 622–7 (Nov. 1974); CPM-7501X0416

Quasilinear theory of beam–generated surface waves in a plasma —V. I. Pakhomov and V. L. Sizonenko. 19(5), 630–4 (Nov. 1974); CPM-7501X0424

Absolute decay instability of low–frequency waves in an inhomogeneous plasma —A. D. Piliya and V. I. Fedorov. 19(5), 686 (Nov. 1974); CPM-7501X0480

Aperiodic instability in a plasma gap with external feedback —A. N. Igritskii. 19(6), 719–21 (Dec. 1974); CPM-7501X0719

Wave interaction in a thin plasma sheath —A. V. Pashchenko and B. N. Rutkevich. 19(6), 726–31 (Dec. 1974); CPM-7501X0726

Propagation and stability of large amplitude ionization waves —M. S. Gorelik and L. D. Tsendin. 19(7), 880–2 (Jan. 1975); CPM-7503X0768

Plasma decay instability in crossed fields —V. I. Farenik, V. V. Vlasov, A. M. Rozhkov, and A. A. Kozharin. 19(8), 1116–7 (Feb. 1975); CPM-7504X1540

Nonlinear interaction between a monochromatic ion-acoustic wave and a plasma —V. P. Indykul. 19(9), 1157–9 (Mar. 1975); CPM-7505X0579

Nonlinear statistical theory for condensation of Langmuir plasmons. III. Energy flux for plasma turbulence —F. Kh. Khakimov and V. N. Tsytovich. 19(10), 1300–2 (Apr. 1975); CPM-7506X0234

Nonlinear effects for the "kink" instability in an electron-ion ring —G. P. Berman. 19(10), 1312–6 (Apr. 1975); CPM-7506X0246

Motion of charged particles in a nonneutral plasma —E. N. Agafonova and L. I. Grechikhin. 19(11), 1488–9 (May 1975); CPM-7506X1242

Nonlinear behavior of monochromatic surface waves excited by a beam —A. B. Kitsenko, I. M. Pankratov, and K. N. Stepanov. 19 (11), 1505–6 (May 1975); CPM-7506X1259

Transformation of nonlinear MHD waves —G. M. Zaslavskii, S. S. Moiseev, and V. V. Mukhin. 19(12), 1534–7 (Jun. 1975); CPM-7508X0408

52.35.J Plasma turbulence

Nonlinear statistical theory of a condensate of plasmons. II. Stochastic heating of plasma ions by large–scale Langmuir turbulence —F. Kh. Khakimov. 19(3), 315–8 (Sep. 1974); CPM-7412X1001

Possible use of the schlieren method to measure characteristics of turbulence —V. G. Ivanov. 19(3), 429–31 (Sep. 1974); CPM-7412X1115

Excitation of acoustic waves by ion–acoustic turbulence —Kh. O. Abdulloev, F. Kh. Khakimov, and V. G. Makhan'kov. 19(4), 441–5 (Oct. 1974); CPM-7412X0225

Plasma acceleration in crossed electric and magnetic fields —V. I. Aref'ev. 19(4), 446–54 (Oct. 1974); CPM-7412X0230

Linear theory for the low–frequency electromagnetic properties of an isotropic turbulent plasma —K. Komilov, F. Kh. Khakimov, and V. N. Tsytovich. 19(5), 615–7 (Nov. 1974); CPM-7501X0409

Optical investigation of a turbulent plasma —Ya. F. Volkov, V. G. Dyatlov, and N. I. Mitina. 19(7), 905–8 (Jan. 1975); CPM-7503X0793

Turbulent plasma heating and the Buneman instability —V. L. Sizonenko. 19(9), 1260–1 (Mar. 1975); CPM-7505X0682

Nonlinear statistical theory for condensation of Langmuir plasmons. III. Energy flux for plasma turbulence —F. Kh. Khakimov and V. N. Tsytovich. 19(10), 1300–2 (Apr. 1975); CPM-7506X0234

Anomalous ion heating in a parametrically unstable plasma —I. S. Baikov and V. P. Silin. 19(12), 1529–33 (Jun. 1975); CPM-7508X0403

52.35.L Shock waves

Multiple reflection of light in a shock tube —V. D. Mironov and V. I. Selyakov. 19(3), 402–4 (Sep. 1974); CPM-7412X1088

Investigation of ionization processes behind strong shock waves using an electrical conductivity probe —V. A. Tishchenko, N. V. Khandurov, and É. K. Chekalin. 19(5), 651–3 (Nov. 1974); CPM-7501X0445

Propagation of shock waves in inhomogeneous media —R. A. Glatman. 19(11), 1390–2 (May 1975); CPM-7506X1144

52.40.– Plasma interactions

Pulsed ion beams from a high-current plasma diode —B. A. Tskhadaya, A. A. Plyutto, and K. V. Suladze. 19(8), 1108–9 (Feb. 1975); CPM-7504X1532

52.40.D Electromagnetic wave propagation in plasma

Effect of ionization and excitation on the penetration of an electromagnetic wave into a weakly ionized plasma —A. G. Boev and A. V. Prokopov. 19(7), 901–4 (Jan. 1975); CPM-7503X0789

Modulation of microwaves by density fluctuations in a plasma —L. A. Dushin, A. V. Serikov, A. I. Skibenko, E. V. Krivorukov, and I. P. Fomin. 19(9), 1163–7 (Mar. 1975); CPM-7505X0585

Energy of charged particles accelerated by electromagnetic waves in a plasma with a spatially decreasing density —V. Ya. Davydovskii and A. S. Ukolov. 19(10), 1303–7 (Apr. 1975); CPM-7506X0237

Parametric excitation of helicon waves in a plasma by modulated radio frequency waves —V. S. Paverman and D. D. Tskhakya. 19 (12), 1629–30 (Jun. 1975); CPM-7508X0503

52.40.F Antennas in plasma; plasma-filled wave guides

Surface waves in periodic plasma systems —V. F. Dryakhlushin and Yu. A. Romanov. 19(7), 883–6 (Jan. 1975); CPM-7503X0771

Solitary waves in anisotropic plasma waveguide —V. I. Kurilko and A. P. Tolstoluzhskii. 19(7), 887–90 (Jan. 1975); CPM-7503X0775

Electromagnetic fields outside a synthesized plasma jet —E. V. Bogdanov, G. M. Mantrova, and M. N. Yakovleva. 19(7), 919–21 (Jan. 1975); CPM-7503X0807

Electron lifetimes in atmosphere at high pressure —V. N. Kapinos, Yu. A. Medvedev, N. N. Morozov, and B. M. Stepanov. 19(11), 1507 (May 1975); CPM-7506X1261

52.40.H Solid-plasma interactions

Direct current in a metal—selenium—metal structure boundary by an rf plasma —A. D. Andreev and S. I. Lubinskii. 19(12), 1606–7 (Jun. 1975); CPM-7508X0480

52.40.K Sheaths

Surface waves in a magnetized plasma in a radio–frequency field —E. E. Lovetskii and A. N. Starodub. 19(3), 319–22 (Sep. 1974); CPM-7412X1005

Damping of ion–acoustic waves in a bounded plasma —A. N. Kondratenko and V. M. Kuklin. 19(3), 326–8 (Sep. 1974); CPM-7412X1012

Resonant amplification of an image potential by an electromagnetic wave —Yu. I. Balkarei and É. M. Épshtein. 19(6), 843–4 (Dec. 1974); CPM-7501X0843

Diffusion regime for electrostatic probes as singular-perturbation problem —I. B. Chekmarev. 19(10), 1287–9 (Apr. 1975); CPM-7506X0221

Nonmonotonic potential distribution in the electrode region —A. I. Loshkarev. 19(10), 1308–11 (Apr. 1975); CPM-7506X0242

Low-pressure self-maintained discharge with suppressed electron drift. I —V. K. Kalashnikov and Yu. V. Sanochkin. 19(12), 1549–53 (Jun. 1975); CPM-7508X0423

Low-pressure self-maintained discharge with suppressed electron drift. II —Yu. V. Sanochkin and V. K. Kalashnikov. 19(12), 1554–8 (Jun. 1975); CPM-7508X0428

52.40.M Beam interactions in plasma

Nonmonoenergetic relativistic electron beam in a bounded collisional plasma —V. P. Grigor'ev and N. S. Shulaev. 19(1), 20–1 (Jul. 1974); CPM-7407X1532

Spatial characteristics and loss of plasma produced by an electron beam in a magnetic trap —M. Yu. Bredikhin, A. I. Maslov, A. I. Skibenko, E. I. Skibenko, I. P. Fomin, and V. B. Yuferov. 19(1), 49–52 (Jul. 1974); CPM-7407X1561

Excitation of electromagnetic ion cyclotron waves by fast ions —T. D. Kaladze, D. G. Lominadze, and K. N. Stepanov. 19(2), 175–6 (Aug. 1974); CPM-7408X1439

Parametric instability of an electron beam in a magnetic field —A. I. Pasynok and N. S. Repalov. 19(2), 177–80 (Aug. 1974); CPM-7408X1441

Conversion of regular charge–density waves in a inhomogeneous plasma —S. S. Kalmykova and A. P. Tolstoluzhskii. 19(4), 455–8 (Oct. 1974); CPM-7412X0239

Excitation of surface electromagnetic waves in a plasma cylinder surrounded by a hollow electron beam —O. V. Dolzhenko, A. V. Zosimov, and A. A. Rukhadze. 19(5), 618–21 (Nov. 1974); CPM-7501X0412

Kinetic plasma instabilities excited by a monoenergetic beam —A. I. Ranyuk and V. L. Sizonenko. 19(5), 628–9 (Nov. 1974); CPM-7501X0422

Quasilinear theory of beam–generated surface waves in a plasma —V. I. Pakhomov and V. L. Sizonenko. 19(5), 630–4 (Nov. 1974); CPM-7501X0424

Electron–beam excited crossed–field discharge —V. A. Saenko and M. M. Kasumov. 19(6), 759–61 (Dec. 1974); CPM-7501X0759

Parametric instability of a spatially moderated electron beam in a magnetic field —N. S. Repalov and V. F. Tyrnov. 19(7), 871–3 (Jan. 1975); CPM-7503X0759

Design of axisymmetric plasma lenses —A. I. Morozov and S. V. Lebedev. 19(8), 996–1000 (Feb. 1975); CPM-7504X1420

Low-frequency oscillations in counter-streaming high-current electron beams —A. F. Timoshenko, D. V. Iremashvili, and Yu. K. Udovichenko. 19(8), 1038–41 (Feb. 1975); CPM-7504X1462

Scattering of an electron beam in a straight *dc* turbulent plasma —Yu. P. Golovanov, L. P. Zakatov, A. S. Kingsep, and A. G. Plakhov. 19(8), 1046–9 (Feb. 1975); CPM-7504X1470

Instabilities in interpenetrating electron and ion beams —I. A. Soloshenko and L. P. Katsubo. 19(10), 1317–20 (Apr. 1975); CPM-7506X0251

Measurement of ion density by the dispersion relation for an ion-beam plasma —M. D. Gabovich, L. P. Katsubo, and I. A. Soloshenko. 19(11), 1412–3 (May 1975); CPM-7506X1166

Rotation of Poynting vector for ultralow-frequency ion waves in an inhomogeneous plasma —Ya. L. Al'pert and R. N. Kaufman. 19 (12), 1519–21 (Jun. 1975); CPM-7508X0393

Interaction of a hollow electron beam with a plasma —N. M. Zemlyanskii, A. K. Berezin, Ya. B. Fainberg, L. I. Bolotin, and S. S. Krivulya. 19(12), 1547–8 (Jun. 1975); CPM-7508X0421

52.50.– Plasma production and heating

Distributed systems for feedback control of a tokamak plasma —V. F. Gubarev and Yu. I. Samoilenko. 19(4), 463–7 (Oct. 1974); CPM-7412X0247

52.50.D Plasma sources

Investigation of spatial distributions in a laser–produced plasma by Hα absorption —G. V. Ostrovskaya and N. A. Pobedonostseva. 19(3), 424–6 (Sep. 1974); CPM-7412X1110

Supersonic plasma jet from a high–power pulsed discharge —M. A. Sultanov. 19(4), 478–82 (Oct. 1974); CPM-7412X0262

Electron–beam excited crossed–field discharge —V. A. Saenko and M. M. Kasumov. 19(6), 759–61 (Dec. 1974); CPM-7501X0759

Low pressure discharge with high–energy electrons —R. A. Demirkhanov, Yu. V. Kursanov, and L. P. Skripal'. 19(7), 891–4 (Jan. 1975); CPM-7503X0779

Plasma synthesis by injection of an electron beam through an ion source —V. F. Virko, M. D. Gabovich, G. S. Kirichenko, and O. K. Nazarenko. 19(11), 1418–20 (May 1975); CPM-7506X1172

Two modes of operation of an arc plasma source in an external magnetic field —A. G. Korsun and S. A. Meshcheryakov. 19(11), 1500–1 (May 1975); CPM-7506X1254

52.50.G Plasma heating

Nonlinear statistical theory of a condensate of plasmons. II. Stochastic heating of plasma ions by large–scale Langmuir turbulence —F. Kh. Khakimov. 19(3), 315–8 (Sep. 1974); CPM-7412X1001

Expansion of a recombining plasma in vacuum —E. E. Lovetskii, A. N. Polyanichev, and V. S. Fetisov. 19(5), 647–50 (Nov. 1974); CPM-7501X0441

Spatial and energy parameters of the relativistic electron beam of the Rius–5 accelerator —A. T. Altyntsev and V. I. Koroteev. 19(6), 773–4 (Dec. 1974); CPM-7501X0773

Linear transient response of a fully ionized plasma in a pulsed electric field —V. V. Istomin, S. P. Sher, and S. P. Dovgopol. 19(7), 963–4 (Jan. 1975); CPM-7503X0851

Turbulent plasma heating and the Buneman instability —V. L. Sizonenko. 19(9), 1260–1 (Mar. 1975); CPM-7505X0682

Anisotropic plasma heating near the lower hybrid frequency —V. M. Glagolev, V. V. Martynenko, and Yu. V. Skosyrev. 19(12), 1543–6 (Jun. 1975); CPM-7508X0417

52.50.J Plasma production and heating by laser beams

Laser-initiated vacuum discharge —V. P. Kovalenko, A. A. Makarevich, V. A. Rodichkin, and A. M. Timonin. 19(11), 1429–31 (May 1975); CPM-7506X1183

52.55.– Plasma equilibrium and confinement

52.55.D General theory

Mechanism for plasma loss from a magnetic trap —V. I. Volosov. 19 (11), 1408–11 (May 1975); CPM-7506X1162

52.55.F Closed-confinement configurations

Magnetic field in a θ pinch with an axial conductor —Ya. F. Volkov, V. G. Dyatlov, and N. I. Mitina. 19(3), 323–5 (Sep. 1974); CPM-7412X1009

Stabilization of the major radius of toroidal pinch by a feedback system —V. V. Arsenin. 19(7), 895–7 (Jan. 1975); CPM-7503X0783

Optical investigation of a turbulent plasma —Ya. F. Volkov, V. G. Dyatlov, and N. I. Mitina. 19(7), 905–8 (Jan. 1975); CPM-7503X0793

Equilibrium in a tokamak with noncircular cross section —L. E. Zakharov. 19(8), 1005–8 (Feb. 1975); CPM-7504X1429

Plasma equilibrium and confinement in a poloidal heliotron configuration. I —V. G. Zykov, V. I. Karpukhin, Yu. F. Lonin, N. N. Podteregera, N. I. Rudnev, and V. T. Tolok. 19(8), 1063–8 (Feb. 1975); CPM-7504X1487

Plasma equilibrium and confinement in a poloidal heliotron configuration. II —V. G. Zykov, V. I. Karpukhin, Yu. F. Lonin, N. N. Podteregera, N. I. Rudnev, A. Y. Skibenko, V. T. Tolok, and I. P. Fomin. 19(8), 1069–72 (Feb. 1975); CPM-7504X1493

Hydrodynamic stability of the Uragan stellarator —V. M. Zalkind, Yu. K. Kuznetsov, V. K. Pashnev, and V. M. Tonkopryad. 19(8), 1123–5 (Feb. 1975); CPM-7504X1547

Energy balance in Tokamaks in the "plateau—banana" transition region —Yu. N. Dnestrovskii and D. P. Kostomarov. 19(12), 1541–2 (Jun. 1975); CPM-7508X0415

52.55.H Open-confinement configurations

Spatial characteristics and loss of plasma produced by an electron beam in a magnetic trap —M. Yu. Bredikhin, A. I. Maslov, A. I. Skibenko, E. I. Skibenko, I. P. Fomin, and V. B. Yuferov. 19(1), 49–52 (Jul. 1974); CPM-7407X1561

Plasma confinement in a time-increasing multipole magnetic field —V. G. Padalka and N. S. Repalov. 19(1), 121–2 (Jul. 1974); CPM-7407X1633

Magnetic field in a θ pinch with an axial conductor —Ya. F. Volkov, V. G. Dyatlov, and N. I. Mitina. 19(3), 323–5 (Sep. 1974); CPM-7412X1009

Radio-frequency absorption in a plasma confined by rf plugs —K. S. Golovanivskii, V. D. Dougar-Jabon, and L. A. Pokhmel'nykh. 19(11), 1484–5 (May 1975); CPM-7506X1238

52.55.J Confinement in fusion reactors

Magnetic topography of toroidal systems —M. N. Skoblik, V. E. Ziser, A. V. Georgievskii, and V. G. Peletminskaya. 19(10), 1277–80 (Apr. 1975); CPM-7506X0211

52.60.+ Relativistic plasma

Method for optical modulation of an electron beam —V. I. Sotnikov. 19(11), 1510–1 (May 1975); CPM-7506X1264

52.70.– Plasma diagnostic techniques and instrumentation

Electron lifetimes in atmosphere at high pressure —V. N. Kapinos, Yu. A. Medvedev, N. N. Morozov, and B. M. Stepanov. 19(11), 1507 (May 1975); CPM-7506X1261

52.70.D Electric and magnetic measurements

Charge-carrier density of the plasma produced in a Penning mixture by irradiation by uranium fission fragments and reactor radiation —G. A. Batyrbekov, Yu. D. Kuznetsov, and Zh. S. Takibaev. 19(5), 645–6 (Nov. 1974); CPM-7501X0439

Diffusion regime for electrostatic probes as singular-perturbation problem —I. B. Chekmarev. 19(10), 1287–9 (Apr. 1975); CPM-7506X0221

Measurement of plasma electron temperature with a sinusoidal probe potential —B. I. Kanaev, V. V. Piterskii, and E. E. Yushmanov. 19(11), 1421–3 (May 1975); CPM-7506X1175

Resistance and inductance of a gas arc —S. I. Barannik, S. B. Vasserman, and A. N. Lukin. 19(11), 1449–53 (May 1975); CPM-7506X1203

Acceleration of plasma electrons in strong electric fields —Z. A. Al'bikov, M. I. Ivanov, V. I. Kazacha, O. V. Kozlov, V. D. Rusanov, and S. S. Sobolev. 19(11), 1498–9 (May 1975); CPM-7506X1252

Hot probe measurements in a rarefied streaming plasma —E. M. Netsvetailov, L. V. Nosachev, and V. V. Skvortsov. 19(12), 1579–83 (Jun. 1975); CPM-7508X0453

Connection of magnetic lines of force in a neutral layer —A. T. Altyntsev and V. I. Krasov. 19(12), 1639–40 (Jun. 1975); CPM-7508X0513

52.70.G Radiofrequency and microwave measurements

Experimental investigation of microwave radiation produced by hypersonic flows —V. A. Lyutomskii, V. M. Polyakov, and V. G. Testov. 19(4), 483–5 (Oct. 1974); CPM-7412X0267

Investigation of ionization processes behind strong shock waves using an electrical conductivity probe —V. A. Tishchenko, N. V. Khandurov, and É. K. Chekalin. 19(5), 651–3 (Nov. 1974); CPM-7501X0445

Electromagnetic fields outside a synthesized plasma jet —E. V. Bogdanov, G. M. Mantrova, and M. N. Yakovleva. 19(7), 919–21 (Jan. 1975); CPM-7503X0807

Measurement of plasma density distribution with a rectangular microwave cavity —I. N. Moskalev. 19(9), 1168–70 (Mar. 1975); CPM-7505X0590

52.70.K Optical measurements

Diagnostics of a laser-produced plasma by a scattering method using an electron-optical image converter —E. A. Burunov, G. M. Malyshev, G. T. Razdobarin, and V. V. Semenov. 19(1), 66–9 (Jul. 1974); CPM-7407X1578

Multiple reflection of light in a shock tube —V. D. Mironov and V. I. Selyakov. 19(3), 402–4 (Sep. 1974); CPM-7412X1088

Optical radiation from nanosecond discharges in dense gases —L. P. Babich. 19(3), 419–20 (Sep. 1974); CPM-7412X1105

Investigation of spatial distributions in a laser-produced plasma by Hα absorption —G. V. Ostrovskaya and N. A. Pobedonostseva. 19(3), 424–6 (Sep. 1974); CPM-7412X1110

Vacuum-UV and soft x-ray emission in a magnetoplasma compressor —P. E. Kovrov and L. G. Tokarev. 19(4), 563–4 (Oct. 1974); CPM-7412X0347

Optical investigation of a turbulent plasma —Ya. F. Volkov, V. G. Dyatlov, and N. I. Mitina. 19(7), 905–8 (Jan. 1975); CPM-7503X0793

Electron temperature in a high-frequency helium discharge —V. S. Voitsenya, A. Yu. Voloshko, V. G. Konovalov, and S. I. Solodovchenko. 19(7), 909–10 (Jan. 1975); CPM-7503X0797

Investigation of a plasma focus with a time-resolved laser interferometer —I. M. Zolototrubov, I. P. Skoblik, A. G. Tolstolutskii, and V. I. Privezentsev. 19(8), 1061–2 (Feb. 1975); CPM-7504X1485

Atomic density in the low-voltage arc in a cesium diode —F. G. Baksht, A. A. Kostin, Yu. L. Serov, and I. P. Yavor. 19(11), 1424–5 (May 1975); CPM-7506X1178

Gasdynamic model of the spark discharge —Yu. K. Bobrov. 19(11), 1442–6 (May 1975); CPM-7506X1196

52.70.N Particle measurements

Production of collimated beams of high-energy electrons —V. I. Nemchenko. 19(1), 91–7 (Jul. 1974); CPM-7407X1603

Electron energy distribution in the afterglow. I —A. B. Blagoev, Yu. M. Kagan, N. B. Kolokolov, and R. I. Lyagushchenko. 19(2), 211–4 (Aug. 1974); CPM-7408X1475

Electron energy distribution in the afterglow. II —A. B. Blagoev, Yu. M. Kagan, N. B. Kolokolov, and R. I. Lyagushchenko. 19(2), 215–9 (Aug. 1974); CPM-7408X1479

Electron energy distribution in a high-freqeuncy discharge in an axial magnetic field —S. D. Vagner, V. A. Virolainen, Yu. M. Kagan, and T. A. Kalmykova. 19(2), 290–1 (Aug. 1974); CPM-7408X1554

New method for obtaining probe characteristics —Yu. I. Osipov. 19(2), 296–8 (Aug. 1974); CPM-7408X1560

Electron energy distribution in helium, nitrogen, and their mixtures —K. D. Asvadurov, I. A. Vasil'eva, and V. M. Torchinskii. 19(3), 354–7 (Sep. 1974); CPM-7412X1040

Effect of ion current on the measurement of the electron energy distribution function by the second-derivative method —V. A. Dovzhenko, A. P. Ershov, and G. S. Solntsev. 19(4), 538–9 (Oct. 1974); CPM-7412X0322

Measurement of plasma ion temperature by a thin probe with $T_i \gtrsim T_e$ —B. I. Kanaev and E. E. Yushmanov. 19(4), 554–5 (Oct. 1974); CPM-7412X0338

Charge-carrier density of the plasma produced in a Penning mixture by irradiation by uranium fission fragments and reactor radiation —G. A. Batyrbekov, Yu. D. Kuznetsov, and Zh. S. Takibaev. 19(5), 645–6 (Nov. 1974); CPM-7501X0439

Conversion of neutral hydrogen into protons in dense plasmas —T. A. Bazilevskaya, L. I. Krupnik, and N. G. Shulika. 19(6), 741–4 (Dec. 1974); CPM-7501X0741

Mass and energy analysis of ions in the cathode of an anomalous glow discharge. II. Binary gas mixtures Ne+Ar and N_2+Ar —A. V. Bondarenko. 19(7), 914–8 (Jan. 1975); CPM-7503X0802

High-frequency modulation of atomic beams for plasma diagnostics —P. A. Demchenko, L. I. Krupnik, K. A. Leontovich, and E. S. Lyangner. 19(10), 1362–6 (Apr. 1975); CPM-7506X0296

Measurement of ion density by the dispersion relation for an ion-beam plasma —M. D. Gabovich, L. P. Katsubo, and I. A. Soloshenko. 19(11), 1412–3 (May 1975); CPM-7506X1166

Free expansion of plasma jets —P. A. Demchenko, L. I. Krupnik, and E. S. Lyangner. 19(11), 1426–8 (May 1975); CPM-7506X1180

52.75.- Plasma devices and applications

Radiation energy of a magnetoplasma compressor —V. I. Berkov and A. I. Morozov. 19(2), 220–3 (Aug. 1974); CPM-7408X1484
Condensation of an erosion plasma —B. A. Osadin and N. V. Rusakov. 19(2), 299–300 (Aug. 1974); CPM-7408X1563
Focusing of a neutralized ion beam by a plasma-optics system —I. I. Demidenko, N. S. Lomino, A. I. Morozov, and V. G. Padalka. 19 (3), 347–50 (Sep. 1974); CPM-7412X1033
Plasma density in a magnetoplasma compressor —A. K. Vinogradova, V. P. Vinogradov, A. I. Morozov, and A. A. Sergeev. 19(3), 421–3 (Sep. 1974); CPM-7412X1107
Plasma diffusion in the Tornado device —A. N. Kozyrev and B. P. Peregud. 19(4), 468–74 (Oct. 1974); CPM-7412X0252

52.75.D Accelerators and propulsion

Experimental investigation of anode processes in a closed electron-drift accelerator —I. V. Melikov. 19(1), 35–7 (Jul. 1974); CPM-7407X1547
Current limiting by self magnetic field in a plasma accelerator —A. G. Korsun. 19(1), 124–6 (Jul. 1974); CPM-7407X1636
Forces in a Hall plasma accelerator —O. N. Mironov. 19(3), 329–34 (Sep. 1974); CPM-7412X1015
Similitude in Hall-current plasma accelerators —A. I. Morozov and I. V. Melikov. 19(3), 340–2 (Sep. 1974); CPM-7412X1026
Equilibrium flow in a Hall-current plasma accelerator —I. V. Melikov. 19(3), 343–6 (Sep. 1974); CPM-7412X1029
Use of plasma accelerator for optical pumping of lasers —N. P. Kozlov and Yu. S. Protasov. 19(3), 358–60 (Sep. 1974); CPM-7412X1044
Plasma acceleration in crossed electric and magnetic fields —V. I. Aref'ev. 19(4), 446–54 (Oct. 1974); CPM-7412X0230
Electron energy spectrum in high-energy nanosecond accelerators —V. V. Kremnev, G. A. Mesyats, and V. P. Reznikov. 19(10), 1342–4 (Apr. 1975); CPM-7506X0276
Formation of a plasma focus in a plasma erosion accelerator. II. Energy characteristics of the dense plasma focus —N. P. Kozlov, L. V. Leskov, Yu. S. Protasov, and V. I. Khvesyuk. 19(12), 1558–9 (Jun. 1975); CPM-7508X0432
Effect of rf ionization on Hall-current plasma accelerator —I. I. Demidenko, N. S. Lomino, A. I. Morozov, and V. G. Padalka. 19 (12), 1560–3 (Jun. 1975); CPM-7508X0434

52.75.F Magnetohydrodynamic generators and thermionic convertors

Optimum dimensions of a coaxial thermionic converter —V. V. Sinyavskii. 19(3), 373–7 (Sep. 1974); CPM-7412X1059
Vacuum-UV and soft x-ray emission in a magnetoplasma compressor —P. E. Kovrov and L. G. Tokarev. 19(4), 563–4 (Oct. 1974); CPM-7412X0347
Charge-carrier density of the plasma produced in a Penning mixture by irradiation by uranium fission fragments and reactor radiation —G. A. Batyrbekov, Yu. D. Kuznetsov, and Zh. S. Takibaev. 19 (5), 645–6 (Nov. 1974); CPM-7501X0439
Model for the low-voltage arc. I. Stationary solution —Yu. Yu. Abramov and G. G. Gladush. 19(6), 745–7 (Dec. 1974); CPM-7501X0745
Model for the low-voltage arc. II. Stability —Yu. Yu. Abramov and G. G. Gladush. 19(6), 748–50 (Dec. 1974); CPM-7501X0748
Interferometer measurement of the neutral cesium distribution in a short low-voltage arc —Yu. L. Serov and I. P. Yavor. 19(6), 751–4 (Dec. 1974); CPM-7501X0751
Effect of molecular hydrogen on a cesium discharge. I —N. D. Morgulis and V. I. Klapchenko. 19(7), 911–3 (Jan. 1975); CPM-7503X0799
Steady-state operation of a surface-ionization thermionic converter —N. V. Volkov, Yu. K. Gus'kov, Yu. I. Kostikov, and V. P. Pashchenko. 19(8), 1129–30 (Feb. 1975); CPM-7504X1553
Analytic model for the arc regime and the thermionic converter —V. D. Bondarenko and A. I. Loshkarev. 19(12), 1564–8 (Jun. 1975); CPM-7508X0438
Thermal diffusion in a mixture of cesium vapor and helium —E. S. Bekmukhambetov and V. A. Donov. 19(12), 1627–8 (Jun. 1975); CPM-7508X0501

52.80.- Electric discharges

Dynamics and emission of coaxial plasma shells in air —A. F. Aleksandrov, V. V. Perebeinos, A. T. Savichev, and I. B. Timofeev. 19(1), 38–42 (Jul. 1974); CPM-7407X1550
Microwave discharge in argon —E. V. Belousov, A. S. Bryukhovetskii, and A. V. Prokopov. 19(1), 53–6 (Jul. 1974); CPM-7407X1565
Effect of cathode emission on the threshold for striations —N. A. Vorob'eva, Yu. M. Kagan, V. M. Milenin, and A. Kh. Muradov. 19(1), 117–8 (Jul. 1974); CPM-7407X1629
Ionization of a gas-discharge gap by fast electrons —O. B. Evdokimov and A. P. Yalovets. 19(1), 138–9 (Jul. 1974); CPM-7407X1650
Ionization and recombination coefficients in a discharge excited by fast electrons —Yu. I. Bychkov, Yu. D. Korolev, and A. P. Khuzeev. 19(1), 140–1 (Jul. 1974); CPM-7407X1652
Switching characteristis of a discharge in water —V. M. Kuleshov, S. L. Nedoseev, V. P. Smirnov, and A. M. Spektor. 19(1), 150–1 (Jul. 1974); CPM-7407X1662
Production of an ion beam by a magnetic system with opposed fields —V. B. Glasko, A. G. Sveshnikov, and N. N. Semashko. 19(2), 201–5 (Aug. 1974); CPM-7408X1465
Physical properties of an electrodeless pulsed discharge in a gas-filled glass cell —Yu. I. Chutov, N. S. Baranchuk, M. R. Lozovich, and V. G. Danilov. 19(2), 224–8 (Aug. 1974); CPM-7408X1488
Efficient ion source —D. Kh. Abdrashitova, V. G. Babaev, and M. B. Guseva. 19(2), 264–6 (Aug. 1974); CPM-7408X1528
Electron energy distribution in a high-freqeuncy discharge in an axial magnetic field —S. D. Vagner, V. A. Virolainen, Yu. M. Kagan, and T. A. Kalmykova. 19(2), 290–1 (Aug. 1974); CPM-7408X1554
Radiating discharges confined by walls —A. F. Aleksandrov, I. S. Marshak, and A. A. Rukhadze. 19(3), 308–14 (Sep. 1974); CPM-7412X0994
Theory of the positive column in neon —Yu. B. Golobovskii, Yu. M. Kagan, and R. I. Lyagushchenko. 19(3), 335–9 (Sep. 1974); CPM-7412X1021
Fast electrons and x rays from nanosecond gas discharges at 0.1–760 torr —L. V. Tarasova, L. N. Khudyakova, T. V. Loiko, and V. A. Tsukerman. 19(3), 351–3 (Sep. 1974); CPM-7412X1037
Stability of field-emission beams in nonsecond discharges —L. P. Babich. 19(3), 371–2 (Sep. 1974); CPM-7412X1057
Optical radiation from nanosecond discharges in dense gases —L. P. Babich. 19(3), 419–20 (Sep. 1974); CPM-7412X1105
Current density of thermionic-field emission into a plasma at moderate fields —I. N. Ostretsov, V. A. Petrosov, A. A. Porotnikov, and B. B. Rodnevich. 19(5), 707–8 (Nov. 1974); CPM-7501X0501
Electron-beam excited crossed-field discharge —V. A. Saenko and M. M. Kasumov. 19(6), 759–61 (Dec. 1974); CPM-7501X0759
Emission characteristics of an explosive gallium cathode —G. N. Fursei and V. M. Zhukov. 19(6), 804–7 (Dec. 1974); CPM-7501X0804
Ion emission into vacuum from a discharge in crossed electric and magnetic fields —V. A. Nikitinskii and A. S. Zakharov. 19(6), 839–40 (Dec. 1974); CPM-7501X0839
Cell for forming electron beams of arbitrary shape in a high-voltage gaseous discharge —I. V. Vagner, É. I. Bolgov, V. F. Grakun, V. L. Gokhfel'd, and V. A. Kudlai. 19(8), 1042–5 (Feb. 1975); CPM-7504X1466
Discharge in a cylindrical diode with surface ionization —V. P. Osoka and A. V. Potarov. 19(9), 1200–4 (Mar. 1975); CPM-7505X0622

52.80.D Conductivity and discharges (low-field and Townsend)

Continuous electron acceleration in a gas discharge —G. D. Alkhazov. 19(5), 658–9 (Nov. 1974); CPM-7501X0452
Formation of molecular ions in an alkali discharge —V. N. Paslen and A. M. Przhonskii. 19(5), 705–6 (Nov. 1974); CPM-7501X0499
Coaxial plasma injector with programmed injection —V. A. Burtsev, V. N. Litunovskii, and M. P. Nadgornaya. 19(6), 736–40 (Dec. 1974); CPM-7501X0736
Breakdown caused by electron bombardment of the surface of an alloy electrode —N. V. Belan, G. I. Kostyuk, and V. A. Pimkin. 19(6), 802–3 (Dec. 1974); CPM-7501X0802
Low pressure discharge with high-energy electrons —R. A. Demirkhanov, Yu. V. Kursanov, and L. P. Skripal'. 19(7), 891–4 (Jan. 1975); CPM-7503X0779

Effect of ionization and excitation on the penetration of an electromagnetic wave into a weakly ionized plasma —A. G. Boev and A. V. Prokopov. 19(7), 901–4 (Jan. 1975); CPM-7503X0789

Effect of molecular hydrogen on a cesium discharge. I —N. D. Morgulis and V. I. Klapchenko. 19(7), 911–3 (Jan. 1975); CPM-7503X0799

Stochastic acceleration of electrons in nanosecond discharges —L. P. Babich. 19(9), 1154–6 (Mar. 1975); CPM-7505X0576

Volt—ampere characteristic of the low-voltage arc. I. Recombination model —P. P. Shcherbinin. 19(11), 1436–41 (May 1975); CPM-7506X1190

Initial stage of a high-current discharge in air —A. F. Aleksandrov, V. V. Perebeinos, A. T. Savichev, and I. B. Timofeev. 19(11), 1490–1 (May 1975); CPM-7506X1244

Low-pressure self-maintained discharge with suppressed electron drift. I —V. K. Kalashnikov and Yu. V. Sanochkin. 19(12), 1549–53 (Jun. 1975); CPM-7508X0423

Low-pressure self-maintained discharge with suppressed electron drift. II —Yu. V. Sanochkin and V. K. Kalashnikov. 19(12), 1554–8 (Jun. 1975); CPM-7508X0428

Gas temperature in the positive column of a medium-β helium discharge —Yu. M. Kagan and K. K. Paskalev. 19(12), 1601–3 (Jun. 1975); CPM-7508X0475

Temperature and electron density in the positive column of a medium-pressure helium discharge —Yu. M. Kagan and K. K. Paskalev. 19(12), 1604–5 (Jun. 1975); CPM-7508X0478

Electrical strength of nitrogen and hyrodgen at high pressures —É. A. Avilov and N. V. Belkin. 19(12), 1631–2 (Jun. 1975); CPM-7508X0505

52.80.H Glow; corona

Electron energy distribution and electrical characteristics of the positive column in H_2 and H_2+Cl_2 —V. V. Zaitsev, A. I. Maksimov, and V. I. Svettsov. 19(1), 57–9 (Jul. 1974); CPM-7407X1569

Production of collimated beams of high-energy electrons —V. I. Nemchenko. 19(1), 91–7 (Jul. 1974); CPM-7407X1603

Effect of electron reflection on the voltage-current characteristics of a high-voltage, hollow-cathode, glow discharge —Ya. Ya. Udris, V. A. Chernov, and L. G. Guseva. 19(1), 134–5 (Jul. 1974); CPM-7407X1646

Electron energy distribution in the afterglow. I —A. B. Blagoev, Yu. M. Kagan, N. B. Kolokolov, and R. I. Lyagushchenko. 19(2), 211–4 (Aug. 1974); CPM-7408X1475

Electron energy distribution in the afterglow. II —A. B. Blagoev, Yu. M. Kagan, N. B. Kolokolov, and R. I. Lyagushchenko. 19(2), 215–9 (Aug. 1974); CPM-7408X1479

Electron density in an argon afterglow —O. P. Bochkova, R. I. Lyagushchenko, É. A. Sukiasyan, and Yu. A. Tolmachev. 19(4), 475–7 (Oct. 1974); CPM-7412X0259

Contraction of the positive column of a glow discharge due to the presence of negative ions —L. A. Mikhalev and L. N. Selin. 19(5), 689–90 (Nov. 1974); CPM-7501X0483

Mass and energy analysis of ions in the cathode of an anomalous glow discharge. II. Binary gas mixtures Ne+Ar and N_2+Ar —A. V. Bondarenko. 19(7), 914–8 (Jan. 1975); CPM-7503X0802

Mode coupling in a double-anode discharge —Yu. G. Zakharenko and V. E. Privalov. 19(7), 980–2 (Jan. 1975); CPM-7503X0868

Mass-spectrometer study of the ion composition of a glow discharge —N. P. Egorov and V. N. Komarov. 19(8), 1100–2 (Feb. 1975); CPM-7504X1524

Radial distribution of density and potential in a glow discharge in CO_2 and water —A. I. Maksimov and V. F. Sokolov. 19(10), 1359–61 (Apr. 1975); CPM-7506X0293

Development of an inhibited glow discharge —Yu. A. Bystrov, S. A. Ivanov, and Yu. F. Radchenko. 19(11), 1447–8 (May 1975); CPM-7506X1201

52.80.M Arcs; sparks

Analysis of the cathode spot in a vacuum arc —I. I. Beilis. 19(2), 251–6 (Aug. 1974); CPM-7408X1515

Emission processes at the cathode of an electric arc —I. I. Beilis. 19 (2), 257–60 (Aug. 1974); CPM-7408X1521

Theory of the positive column in neon —Yu. B. Golobovskii, Yu. M. Kagan, and R. I. Lyagushchenko. 19(3), 335–9 (Sep. 1974); CPM-7412X1021

Electron energy distribution in helium, nitrogen, and their mixtures —K. D. Asvadurov, I. A. Vasil'eva, and V. M. Torchinskii. 19(3), 354–7 (Sep. 1974); CPM-7412X1040

Effects of ion microfields on emission of an arc cathode —A. M. Dorodnov, V. B. Davydov, A. V. Kozyrev, and Ya. A. Pomelov. 19(3), 390–3 (Sep. 1974); CPM-7412X1076

Theory of the low-voltage arc in a narrow gap —F. G. Baksht, A. A. Kostin, and V. A. Nemchinskii. 19(5), 654–7 (Nov. 1974); CPM-7501X0448

Model for the low-voltage arc. I. Stationary solution —Yu. Yu. Abramov and G. G. Gladush. 19(6), 745–7 (Dec. 1974); CPM-7501X0745

Model for the low-voltage arc. II. Stability —Yu. Yu. Abramov and G. G. Gladush. 19(6), 748–50 (Dec. 1974); CPM-7501X0748

Interferometer measurement of the neutral cesium distribution in a short low-voltage arc —Yu. L. Serov and I. P. Yavor. 19(6), 751–4 (Dec. 1974); CPM-7501X0751

Stability of ball lightning —I. P. Stakhanov. 19(7), 861–4 (Jan. 1975); CPM-7503X0749

Nonequilibrium ionization in the cathode region of a high-pressure arc —S. P. Reshenov. 19(8), 1073–5 (Feb. 1975); CPM-7504X1497

Nonmonotonic potential distribution in the electrode region —A. I. Loshkarev. 19(10), 1308–11 (Apr. 1975); CPM-7506X0242

Electrical characteristics of underwater exploding wires —V. K. Sholom, E. V. Krivitskii, and V. P. Litvinenko. 19(10), 1329–31 (Apr. 1975); CPM-7506X0263

Analytic model of the cesium arc —V. P. Pashchenko, V. L. Mironovich, and I. P. Stakhanov. 19(10), 1332–6 (Apr. 1975); CPM-7506X0266

Atomic density in the low-voltage arc in a cesium diode —F. G. Baksht, A. A. Kostin, Yu. L. Serov, and I. P. Yavor. 19(11), 1424–5 (May 1975); CPM-7506X1178

Volt—ampere characteristic of the low-voltage arc. I. Recombination model —P. P. Shcherbinin. 19(11), 1436–41 (May 1975); CPM-7506X1190

Gasdynamic model of the spark discharge —Yu. K. Bobrov. 19(11), 1442–6 (May 1975); CPM-7506X1196

Resistance and inductance of a gas arc —S. I. Barannik, S. B. Vasserman, and A. N. Lukin. 19(11), 1449–53 (May 1975); CPM-7506X1203

Electron energy distribution in a constricted, low-pressure hydrogen discharge —M. A. Abroyan, Yu. M. Kagan, N. B. Kolokolov, and B. P. Lavrov. 19(11), 1492–3 (May 1975); CPM-7506X1246

Two modes of operation of an arc plasma source in an external magnetic field —A. G. Korsun and S. A. Meshcheryakov. 19(11), 1500–1 (May 1975); CPM-7506X1254

Analytic model for the arc regime and the thermionic converter —V. D. Bondarenko and A. I. Loshkarev. 19(12), 1564–8 (Jun. 1975); CPM-7508X0438

Anomalous high emission of a nonevaporating thermionic cathode in an arc —B. Ya. Moizhes and V. A. Nemchinskii. 19(12), 1571–6 (Jun. 1975); CPM-7508X0445

High-pressure hot-cathode arc without forced cooling —V. A. Nemchinskii. 19(12), 1577–8 (Jun. 1975); CPM-7508X0451

52.80.P High-frequency discharge

High-frequency discharge in a mercury—helium mixture —S. D. Vagner, Yu. M. Kagan, A. I. Konstantinov, and I. S. Niskonen. 19 (7), 898–900 (Jan. 1975); CPM-7503X0786

Electron temperature in a high-frequency helium discharge —V. S. Voitsenya, A. Yu. Voloshko, V. G. Konovalov, and S. I. Solodovchenko. 19(7), 909–10 (Jan. 1975); CPM-7503X0797

Drift instability in a weakly ionized plasma —S. V. Putvinskii and A. V. Timofeev. 19(10), 1295–9 (Apr. 1975); CPM-7506X0229

Direct current in a metal—selenium—metal structure boundary by an rf plasma —A. D. Andreev and S. I. Lubinskii. 19(12), 1606–7 (Jun. 1975); CPM-7508X0480

52.80.Q Explosions

Nanosecond x-ray pulses —G. A. Mesyats. 19(7), 948–51 (Jan. 1975); CPM-7503X0836

Simplified model for the initial stage of exploding wire phenomena —N. N. Stolovich, V. G. Maksimov, and N. S. Minitskaya. 19(10), 1321–8 (Apr. 1975); CPM-7506X0255

Electrical characteristics of underwater exploding wires —V. K. Sholom, E. V. Krivitskii, and V. P. Litvinenko. 19(10), 1329–31 (Apr. 1975); CPM-7506X0263

Electron energy spectrum in high-energy nanosecond accelerators —V. V. Kremnev, G. A. Mesyats, and V. P. Reznikov. 19(10), 1342–4 (Apr. 1975); CPM-7506X0276

Electrical explosion of the metastable liquid phases of zinc, cadmium, and lead —M. M. Martynyuk and I. Karimkhodzhaev. 19(11), 1454–7 (May 1975); CPM-7506X1208

Resistance and enthalpy of refractory exploding wires —M. M. Martynyuk, I. Karimkhodzhaev, and V. I. Tsapkov. 19(11), 1458–61 (May 1975); CPM-7506X1212

Dielectric breakdown of detonation products —V. L. Korol'kov, M. A. Mel'nikov, and A. P. Tsyplenko. 19(12), 1569–70 (Jun. 1975); CPM-7508X0443

52.80.V Discharge in vacuum

Laser-initiated vacuum discharge —V. P. Kovalenko, A. A. Makarevich, V. A. Rodichkin, and A. M. Timonin. 19(11), 1429–31 (May 1975); CPM-7506X1183

Electrical breakdown of vacuum gaps under superhigh voltage pulses —I. I. Kalyatskii, G. M. Kassirov, and G. V. Smirnov. 19(11), 1434–5 (May 1975); CPM-7506X1188

52.90.+ Other topics in plasma physics and electric discharges

Electric field and plasma structure near a large charged body —L. A. Malyavin and A. M. Moskalenko. 19(2), 197–200 (Aug. 1974); CPM-7408X1461

Structure of a perturbation near a highly charged body in a weakly ionized plasma —L. A. Malyavin and A. M. Moskalenko. 19(2), 206–10 (Aug. 1974); CPM-7408X1470

Stability of ball lightning —I. P. Stakhanov. 19(7), 861–4 (Jan. 1975); CPM-7503X0749

61. STRUCTURE OF LIQUIDS AND SOLIDS; CRYSTALLOGRAPHY

61.80.- Radiation damage and other irradiation effects

Effect of crystal structure on certain angular dependence of the ion–electron–emission yield —B. A. Brusilovskii and V. A. Molchanov. 19(1), 84–7 (Jul. 1974); CPM-7407X1596

Investigation of the work function of a tungsten cathode after bombardment by inert–gas ions —P. N. Chistyakov, R. A. Milovanova, and V. V. Lytkin. 19(1), 148–9 (Jul. 1974); CPM-7407X1660

Energy dependence of the focusing of ions by crystals —E. S. Mashkova, V. A. Molchanov, and A. D. Pavlova. 19(4), 540 (Oct. 1974); CPM-7412X0324

Dielectric strength of a vacuum gap with electrodes irradiated with He^+ and H^+ ions —A. P. Solodovnikov and Yu. M. Khirnyi. 19 (8), 1122 (Feb. 1975); CPM-7504X1546

Effect of a high-current relativistic electron beam on a metal —B. I. Dmitrenko, L. V. Leskov, G. P. Maksimov, S. L. Nedoseev, V. V. Savichev, V. P. Smirnov, and A. M. Spektor. 19(9), 1224–5 (Mar. 1975); CPM-7505X0646

61.90.+ Other topics in structure of liquids and solids

Crystal defects of heterostructures of AlAs–GaAs solid solutions and effect on the characteristics of injection lasers —L. V. Druzhinina, V. T. Bublik, L. M. Dolginov, P. G. Eliseev, M. P. Kerbelev, V. B. Osvenskii, I. Z. Pinsker, and M. G. Shumskii. 19(7), 935–9 (Jan. 1975); CPM-7503X0823

Liquid crystals in external fields —I. V. Ioffe. 19(8), 1012–5 (Feb. 1975); CPM-7504X1436

Impurities and crystal dimensions in zone refining —V. G. Glebovskii and B. M. Shipilevskii. 19(9), 1231–5 (Mar. 1975); CPM-7505X0653

Coherent Compton effect in crystals —V. A. Bushuev and R. N. Kuz'min. 19(12), 1590–2 (Jun. 1975); CPM-7508X0464

62. MECHANICAL AND ACOUSTIC PROPERTIES OF CONDENSED MATTER

Optical characteristics of K–8 glass subject to radiation from a neodymium laser —A. M. Bonch–Bruevich, Ya. A. Imas, V. S. Salyadinov, and A. V. Shatilov. 19(2), 287–9 (Aug. 1974); CPM-7408X1551

Hologram interferometry for vibration analysis —V. S. Listovets and Yu. I. Ostrovskii. 19(7), 847–60 (Jan. 1975); CPM-7503X0735

Optical methods for studying amplification of elastic surface waves in a stratified system —I. B. Yakovkin, V. V. Petrov, and S. V. Bogdanov. 19(9), 1242–5 (Mar. 1975); CPM-7505X0664

Excitation of thermoelastic vibrations of a thin plate by a beam of fast charged particles —A. I. Kalinichenko and V. T. Lazurik-Él'tsufin. 19(10), 1382–3 (Apr. 1975); CPM-7506X0316

64. EQUATIONS OF STATE, PHASE EQUILIBRIA, AND PHASE TRANSITIONS

64.70.- Phase equilibria, phase transitions, and critical points

Condensation of a dense vapor flow —V. G. Dneprovskii, B. A. Osadin, and N. V. Rusakov. 19(2), 271–4 (Aug. 1974); CPM-7408X1535

Rate for evaporation of a liquid into vacuum —A. P. Andreev and M. A. Gurevich. 19(3), 396–401 (Sep. 1974); CPM-7412X1082

Vaporization and boiling of liquid metal in an exploding wire —M. M. Martynyuk. 19(6), 793–7 (Dec. 1974); CPM-7501X0793

Electrical explosion of the metastable liquid phases of zinc, cadmium, and lead —M. M. Martynyuk and I. Karimkhodzhaev. 19(11), 1454–7 (May 1975); CPM-7506X1208

65. THERMAL PROPERTIES OF CONDENSED MATTER

Thermal effect of continuous laser radiation on optically transparent media —N. S. Bardina, A. I. Portnyagin, M. Yu. Sklyarov, and A. A. Churin. 19(4), 491–4 (Oct. 1974); CPM-7412X0275

Variational analysis of thermal breakdown of a semiconductor irradiated by light —V. L. Komolov. 19(5), 600–2 (Nov. 1974); CPM-7501X0394

Vaporization and boiling of liquid metal in an exploding wire —M. M. Martynyuk. 19(6), 793–7 (Dec. 1974); CPM-7501X0793

Excitation of thermoelastic vibrations of a thin plate by a beam of fast charged particles —A. I. Kalinichenko and V. T. Lazurik-Él'tsufin. 19(10), 1382–3 (Apr. 1975); CPM-7506X0316

66. TRANSPORT PROPERTIES OF CONDENSED MATTER (NONELECTRONIC)

66.30.- Diffusion in solids

Behavior of molten salts in strong electric fields —A. Z. Éfendiev, O. M. Shabanov, S. M. Gadzhiev, and S. M. Tagirov. 19(6), 820–3 (Dec. 1974); CPM-7501X0820

Atomic diffusion from a finite film over a solid surface —Yu. D. Kornyushkin. 19(7), 971–2 (Jan. 1975); CPM-7503X0859

Diffusion and solubility of helium in potassium chloride —A. Ya. Kupryazhkin, P. V. Volobuev, and P. E. Suetin. 19(8), 1105–7 (Feb. 1975); CPM-7504X1529

66.90.+ Other topics in nonelectronic transport properties

Thermoacoustic waves in conducting gases and liquids —P. A. Andreev. 19(6), 845–6 (Dec. 1974); CPM-7501X0845

Thermal conditions for a sandwich cold cathode —F. M. Benson, P. E. Troyan, and Yu. B. Yankelevich. 19(7), 946–7 (Jan. 1975); CPM-7503X0834

Atomic diffusion from a finite film over a solid surface —Yu. D. Kornyushkin. 19(7), 971–2 (Jan. 1975); CPM-7503X0859

68. SURFACES AND INTERFACES; THIN FILMS AND WHISKERS

68.40.– Chemical reactions and surface treatment

Preservation of semiconductor field–emission cathodes —N. V. Egorov, G. N. Fursei, and M. K. El'Nimr. 19(5), 709 (Nov. 1974); CPM-7501X0503

Effects of cleaning on adsorption by germanium single crystals —Yu. I. Belyakov, M. P. Volkov, and T. N. Kompaniets. 19(6), 815–6 (Dec. 1974); CPM-7501X0815

Characteristics of diffraction gratings obtained by photoetching of semiconductor surfaces —L. V. Belyakov, D. N. Goryachev, M. N. Mizerov, and E. L. Portnoi. 19(6), 837–8 (Dec. 1974); CPM-7501X0837

68.90.+ Other topics in the structure and nonelectronic properties of surfaces and thin films

Method for studying gas creep along a solid surface —B. M. Markeev. 19(5), 700–1 (Nov. 1974); CPM-7501X0494

Atomic recombination on a solid surface —V. P. Pinchuk, A. N. Gorban', and V. G. Kornich. 19(6), 808–10 (Dec. 1974); CPM-7501X0808

Capillary gravitational waves and the mechanogalvanic effect —E. D. Korlyakov. 19(7), 965 (Jan. 1975); CPM-7503X0853

72. ELECTRONIC TRANSPORT IN CONDENSED MATTER

72.10.– Electronic conduction in metals and alloys

Behavior of molten salts in strong electric fields —A. Z. Éfendiev, O. M. Shabanov, S. M. Gadzhiev, and S. M. Tagirov. 19(6), 820–3 (Dec. 1974); CPM-7501X0820

Effect of temperature-dependent conductivity on electromagnetic field, current, temperature, and impedance in a plane conductor. I —R. S. Kuznetskii. 19(8), 1016–9 (Feb. 1975); CPM-7504X1440

Electrical conductivity of a pseudoliquefied layer in an electric field —V. V. Gal', V. I. Konov, and K. A. Nikitin. 19(9), 1214–5 (Mar. 1975); CPM-7505X0636

72.20.– Conductivity phenomena in semiconductors and insulators

Conductivity of a medium with inhomogeneous inclusions in a magnetic field —Yu. P. Emets. 19(5), 586–8 (Nov. 1974); CPM-7501X0380

Preservation of semiconductor field–emission cathodes —N. V. Egorov, G. N. Fursei, and M. K. El'Nimr. 19(5), 709 (Nov. 1974); CPM-7501X0503

Direct current in a metal—selenium—metal structure boundary by an rf plasma —A. D. Andreev and S. I. Lubinskii. 19(12), 1606–7 (Jun. 1975); CPM-7508X0480

72.90.+ Other topics in electronic transport in condensed matter

Acousto-electric waves in conducting media —P. A. Andreev. 19(8), 1001–4 (Feb. 1975); CPM-7504X1425

Rectangular conducting wedge in a moving electromagnetic field —I. D. Maergoiz and L. P. Nizhnik. 19(10), 1281–6 (Apr. 1975); CPM-7506X0215

Shot noise in a thermionic cathode —A. F. Golubentsev and A. S. Shapovalov. 19(10), 1345–6 (Apr. 1975); CPM-7506X0279

Dependence of the basic parameters of $Al_xGa_{1-x}As$—GaAs solar converters on temperature and optical intensity —E. B. Vinogradova, M. B. Kagan, N. S. Koroleva, T. L. Lyubashevskaya, and T. A. Nuller. 19(10), 1378–81 (Apr. 1975); CPM-7506X0312

73. ELECTRONIC STRUCTURE AND ELECTRICAL PROPERTIES OF SURFACES, INTERFACES, AND THIN FILMS

73.30.+ Surface double layers, Schottky barriers, and work functions

Effect of selenium and sulfur on the work function of tungsten —N. V. Volkov, Yu. K. Gus'kov, Z. N. Kononova, and Yu. I. Kostikov. 19(1), 144–5 (Jul. 1974); CPM-7407X1656

Investigation of the work function of a tungsten cathode after bombardment by inert–gas ions —P. N. Chistyakov, R. A. Milovanova, and V. V. Lytkin. 19(1), 148–9 (Jul. 1974); CPM-7407X1660

Resonant amplification of an image potential by an electromagnetic wave —Yu. I. Balkarei and É. M. Épshtein. 19(6), 843–4 (Dec. 1974); CPM-7501X0843

73.90.+ Other topics in electrical properties of surfaces, interfaces, and thin films

Displacement of ion–current retardation curves in surface ionization in a strong field —N. I. Ionov. 19(1), 146–7 (Jul. 1974); CPM-7407X1658

Capillary gravitational waves and the mechanogalvanic effect —E. D. Korlyakov. 19(7), 965 (Jan. 1975); CPM-7503X0853

Rectangular conducting wedge in a moving electromagnetic field —I. D. Maergoiz and L. P. Nizhnik. 19(10), 1281–6 (Apr. 1975); CPM-7506X0215

Direct current in a metal—selenium—metal structure boundary by an rf plasma —A. D. Andreev and S. I. Lubinskii. 19(12), 1606–7 (Jun. 1975); CPM-7508X0480

74. SUPERCONDUCTIVITY

Shielding properties of superconducting shields —S. I. Bondarenko, S. S. Vinogradov, G. A. Gogadze, S. S. Perepelkin, and V. I. Sheremet. 19(6), 824–8 (Dec. 1974); CPM-7501X0824

Superconducting magnetic shields —S. I. Bondarenko and V. I. Sheremet. 19(7), 952–5 (Jan. 1975); CPM-7503X0840

75. MAGNETIC PROPERTIES AND MATERIALS

Magnetoacoustic transducer based on the domain structure of a ferromagnetic material —G. L. Gurevich and G. A. Vul'gal'ter. 19 (1), 154–5 (Jul. 1974); CPM-7407X1666

Distortion of single-turn solenoids in ultrahigh magnetic fields —G. A. Shneerson. 19(10), 1371–7 (Apr. 1975); CPM-7506X0305

76. MAGNETIC RESONANCES AND RELAXATION IN CONDENSED MATTER; MÖSSBAUER EFFECT

Dynamic magnetic–resonance phenomena —P. S. Kuts and V. S. Mel'nik. 19(1), 110–4 (Jul. 1974); CPM-7407X1622

77. DIELECTRIC PROPERTIES AND MATERIALS

77.20.+ Permittivity

Dielectric properties of foamed ceramics at millimeter wavelengths —N. A. Irisova, G. V. Kozlov, V. E. Mandrusov, B. S. Cherepanov, and I. M. Chernyshev. 19(1), 103–4 (Jul. 1974); CPM-7407X1615

Contribution of multiphoton processes to the linear dielectric constant —V. A. Bushuev and R. N. Kuz'min. 19(1), 116 (Jul. 1974); CPM-7407X1628

Calculation of permittivity of an inhomogeneous dielectric by a variational method —G. A. Ermakov, A. G. Fokin, and T. D. Shermergor. 19(2), 157–60 (Aug. 1974); CPM-7408X1421

Calculation of bounds for the effective permittivity of an inhomogeneous dielectric —G. A. Ermakov, A. G. Fokin, and T. D. Shermergor. 19(2), 161–5 (Aug. 1974); CPM-7408X1425

Temperature dependence of the dielectric permittivity of single–crystal TiO$_2$ in the submillimeter range —A. A. Volkov, N. A. Irisova, and G. V. Kozlov. 19(4), 567–8 (Oct. 1974); CPM-7412X0351

Dispersion of the dielectric constant of crystalline KH$_2$PO$_4$ near the "soft" mode frequency —V. V. Meriakri, Yu. M. Poplavko, and E. F. Ushatkin. 19(5), 703–4 (Nov. 1974); CPM-7501X0497

77.90.+ Other topics in dielectric properties and materials

Investigating prebreakdown fields in water by means of the Kerr effect —I. T. Ovchinnikov, K. V. Yanshin, and É. V. Yanshin. 19(2), 294–5 (Aug. 1974); CPM-7408X1558

Nonlinear polarizability of a gaseous medium in a longitudinal magnetic field —V. A. Sokolov and L. M. Khayutin. 19(5), 589–91 (Nov. 1974); CPM-7501X0383

Effect of a high–frequency electric field on the energy loss of a charged particle in a medium —Zh. M. Diasamidze. 19(5), 687–8 (Nov. 1974); CPM-7501X0481

Convection in a liquid dielectric in a longitudinal electric field —I. V. Ioffe and N. V. Kalinin. 19(5), 692 (Nov. 1974); CPM-7501X0486

Dispersion of the dielectric constant of crystalline KH$_2$PO$_4$ near the "soft" mode frequency —V. V. Meriakri, Yu. M. Poplavko, and E. F. Ushatkin. 19(5), 703–4 (Nov. 1974); CPM-7501X0497

Microwave propagation in a low–loss dielectric —L. É. Rikenglaz. 19 (6), 713–4 (Dec. 1974); CPM-7501X0713

Liquid crystals in external fields —I. V. Ioffe. 19(8), 1012–5 (Feb. 1975); CPM-7504X1436

Radiation yield of ions in liquid dielectrics as a function of temperature and radiation energy —V. I. Ivanov, E. D. Kleshchenko, Yu. P. Sukhanovskii, and V. V. Frolov. 19(11), 1468–70 (May 1975); CPM-7506X1222

Dielectric breakdown of detonation products —V. L. Korol'kov, M. A. Mel'nikov, and A. P. Tsyplenko. 19(12), 1569–70 (Jun. 1975); CPM-7508X0443

78. OPTICAL PROPERTIES AND CONDENSED-MATTER SPECTROSCOPY AND OTHER INTERACTIONS OF MATTER WITH PARTICLES AND RADIATION

78.20.– Optical properties and materials

Dielectric properties of foamed ceramics at millimeter wavelengths —N. A. Irisova, G. V. Kozlov, V. E. Mandrusov, B. S. Cherepanov, and I. M. Chernyshev. 19(1), 103–4 (Jul. 1974); CPM-7407X1615

Optical characteristics of K–8 glass subject to radiation from a neodymium laser —A. M. Bonch–Bruevich, Ya. A. Imas, V. S. Salyadinov, and A. V. Shatilov. 19(2), 287–9 (Aug. 1974); CPM-7408X1551

Investigating prebreakdown fields in water by means of the Kerr effect —I. T. Ovchinnikov, K. V. Yanshin, and É. V. Yanshin. 19(2), 294–5 (Aug. 1974); CPM-7408X1558

78.70.– Other interactions of matter with particles and radiation

X–ray fluorescence of oxygen in H$_2$O —L. A. Smirnov. 19(5), 702 (Nov. 1974); CPM-7501X0496

Microwave propagation in a low–loss dielectric —L. É. Rikenglaz. 19 (6), 713–4 (Dec. 1974); CPM-7501X0713

Coherent Compton effect in crystals —V. A. Bushuev and R. N. Kuz'min. 19(12), 1590–2 (Jun. 1975); CPM-7508X0464

78.90.+ Other topics in optical properties of condensed matter

Strobe unit for measuring luminescence in the range 10^{-7}–$2\cdot10^{-10}$ sec —V. A. Bonch–Bruevich and N. A. Tolstoi. 19(2), 284–6 (Aug. 1974); CPM-7408X1548

Variational analysis of thermal breakdown of a semiconductor irradiated by light —V. L. Komolov. 19(5), 600–2 (Nov. 1974); CPM-7501X0394

Microwave maser with nonrelativistic electrons —A. S. Dement'ev and Yu. G. Pavlenko. 19(5), 694–5 (Nov. 1974); CPM-7501X0488

Lasing properties of Yb^{3+} and Er^{3+} glass laser pumped by a laser —V. N. Kalinin, A. A. Mak, D. S. Prilezhaev, and V. A. Fromzel'. 19 (6), 835–6 (Dec. 1974); CPM-7501X0835

Radiation from a charged particle moving close to an anisotropic dielectric —A. I. Plis and N. M. Safikhodzhaev. 19(7), 865–7 (Jan. 1975); CPM-7503X0753

Electroluminescence spectra of the red luminescent diodes p–Al$_x$Ga$_{1-x}$As—n–Al$_y$Ga$_{1-y}$As($y>x$) —V. M. Busov, D. Z. Garbuzov, A. T. Gorelenok, and D. S. Kop'ev. 19(12), 1598–600 (Jun. 1975); CPM-7508X0472

79. ELECTRON AND ION EMISSION BY LIQUIDS AND SOLIDS; IMPACT PHENOMENA

79.20.– Impact phenomena, including electron spectra and sputtering

Effect of crystal structure on certain angular dependence of the ion–electron–emission yield —B. A. Brusilovskii and V. A. Molchanov. 19(1), 84–7 (Jul. 1974); CPM-7407X1596

Nonradiative electron transitions and thermal effects in laser–irradiated transparent dielectrics —B. I. Makshantsev, A. A. Kovalev, R. K. Leonov, and P. A. Yampol'skii. 19(1), 98–102 (Jul. 1974); CPM-7407X1610

Optical characteristics of K–8 glass subject to radiation from a neodymium laser —A. M. Bonch–Bruevich, Ya. A. Imas, V. S. Salyadinov, and A. V. Shatilov. 19(2), 287–9 (Aug. 1974); CPM-7408X1551

Energy losses of slow electrons reflected from molybdenum and tungsten single crystals —O. M. Artamonov, B. B. Bolotov, and M. V. Kremkov. 19(8), 1103–4 (Feb. 1975); CPM-7504X1527

Dielectric strength of a vacuum gap with electrodes irradiated with He$^+$ and H$^+$ ions —A. P. Solodovnikov and Yu. M. Khirnyi. 19 (8), 1122 (Feb. 1975); CPM-7504X1546

Kinetic energy of ions produced by surface ionization. I. Distribution over the velocity components —L. V. Sumin. 19(9), 1205–9 (Mar. 1975); CPM-7505X0627

Cumulative destruction of transparent dielectrics in repeated laser irradiation —L. D. Khazov, I. A. Fersman, and V. Yu. Bortniker. 19(9), 1256–7 (Mar. 1975); CPM-7505X0678

Interaction of intense laser radiation with solid targets —L. V. Dubovoi, V. D. Dyatlov, V. I. Kryzhanovskii, A. A. Mak, R. N. Medvedev, A. N. Popytaev, V. A. Serebryakov, V. N. Sizov, and A. D. Starikov. 19(11), 1477–9 (May 1975); CPM-7506X1231

Mass spectrum of secondary ions ejected from the surface of a single crystal of gallium arsenide by argon ions —A. G. Koval', V. V. Bobkov, Yu. A. Klimovskii, S. S. Strel'chenko, V. V. Shubina, V. V. Lebedev, and Ya. M. Fogel'. 19(12), 1587–9 (Jun. 1975); CPM-7508X0461

Neutral particles from the interaction of laser radiation with a solid target —Yu. A. Bykovskii, N. M. Vasil'ev, I. D. Laptev, and V. N. Nevolin. 19(12), 1635 (Jun. 1975); CPM-7508X0509

79.40.+ Thermionic emission

Extrapolation of the Langmuir S–curve to cesium pressures of 10–100 torr —V. E. Dubinskii and S. Ya. Lebedev. 19(1), 81–3 (Jul. 1974); CPM-7407X1593

Electron–microscope and x–ray study of thermionic emitters made from Mo–Pt alloys —B. B. Shishkin and R. S. Bakhtiyarov. 19(2), 243–50 (Aug. 1974); CPM-7408X1507

Current density of thermionic–field emission into a plasma at moderate fields —I. N. Ostretsov, V. A. Petrosov, A. A. Porotnikov, and B. B. Rodnevich. 19(5), 707–8 (Nov. 1974); CPM-7501X0501

Transient thermionic–field emission from a point cathode —E. A. Litvinov and A. F. Shubin. 19(8), 1131–2 (Feb. 1975); CPM-7504X1555

Thermionic emission properties of zirconium, hafnium, and titanium nitrides in cesium vapor —M. A. Eremeev, V. S. Neshpor, A. B. Novikov, E. M. Stefanovskaya, and V. P. Fedorinov. 19(10), 1337–41 (Apr. 1975); CPM-7506X0271

Anomalous high emission of a nonevaporating thermionic cathode in an arc —B. Ya. Moizhes and V. A. Nemchinskii. 19(12), 1571–6 (Jun. 1975); CPM-7508X0445

79.70.+ Field emission and field ionization

Ion emission into vacuum from a discharge in crossed electric and magnetic fields —V. A. Nikitinskii and A. S. Zakharov. 19(6), 839–40 (Dec. 1974); CPM-7501X0839

Transient thermionic-field emission from a point cathode —E. A. Litvinov and A. F. Shubin. 19(8), 1131–2 (Feb. 1975); CPM-7504X1555

Recent developments in surface ionization (review) —É. Ya. Zandberg. 19(9), 1133–44 (Mar. 1975); CPM-7505X0555

Multiphase, uniform, secondary-emission microwave discharge at a solid surface —G. S. Luk'yanchikov. 19(9), 1196–9 (Mar. 1975); CPM-7505X0618

Emission parameters of a field-emission cathode —G. N. Freiberg. 19 (10), 1352–4 (Apr. 1975); CPM-7506X0286

79.90.+ Other topics in emission and impact phenomena in condensed matter

Time dependence of ion currents produced through surface ionization. Ionization of Ba on the (111) face of iridium —É. Ya. Zandberg, E. V. Rut'kov, and A. Ya. Tontegode. 19(2), 261–3 (Aug. 1974); CPM-7408X1525

Breakdown caused by electron bombardment of the surface of an alloy electrode —N. V. Belan, G. I. Kostyuk, and V. A. Pimkin. 19(6), 802–3 (Dec. 1974); CPM-7501X0802

Emission characteristics of an explosive gallium cathode —G. N. Fursei and V. M. Zhukov. 19(6), 804–7 (Dec. 1974); CPM-7501X0804

Atomic recombination on a solid surface —V. P. Pinchuk, A. N. Gorban', and V. G. Kornich. 19(6), 808–10 (Dec. 1974); CPM-7501X0808

Excitation of thermoelastic vibrations of a thin plate by a beam of fast charged particles —A. I. Kalinichenko and V. T. Lazurik-Él'tsufin. 19(10), 1382–3 (Apr. 1975); CPM-7506X0316

81. MATERIALS SCIENCE AND METALLURGY

81.20.– Methods of crystal growth and purification, including film deposition techniques

Effect of focusing conditions on the morphology of surface films produced with a laser —V. G. Dneprovskii and B. A. Osadin. 19 (2), 275–7 (Aug. 1974); CPM-7408X1539

Condensation of an erosion plasma —B. A. Osadin and N. V. Rusakov. 19(2), 299–300 (Aug. 1974); CPM-7408X1563

Impurities and crystal dimensions in zone refining —V. G. Glebovskii and B. M. Shipilevskii. 19(9), 1231–5 (Mar. 1975); CPM-7505X0653

81.35.– Vacuum metallurgy

Transient molecular effusion characteristics —Yu. N. Lyubitov and V. Z. Belen'kii. 19(4), 519–22 (Oct. 1974); CPM-7412X0303

Adsorption of bismuth on tungsten. I. Steady-state processes —M. A. Mittsev. 19(6), 811–4 (Dec. 1974); CPM-7501X0811

Evaporation rates of the system $ZrC+x\%W$ for the temperature range 2300-3000°K —N. M. Karnaukhova, V. A. Luknitskii, and I. A. Maslov. 19(8), 1096–9 (Feb. 1975); CPM-7504X1520

Composition of adsorbing and desorbing fluxes —Yu. A. Gel'man, V. I. Mikhailov, V. F. Vinogradov, and Yu. N. Lyubitov. 19(10), 1355–8 (Apr. 1975); CPM-7506X0289

Elimination of carbon impurities from platinum by heating in an oxygen atmosphere —L. P. Rekova, V. V. Mozgin, L. N. Zvyagintseva, V. N. Bondarenko, and Ya. M. Fogel'. 19(11), 1465–7 (May 1975); CPM-7506X1219

81.40.+ Ceramics and refractories

Dielectric properties of foamed ceramics at millimeter wavelengths —N. A. Irisova, G. V. Kozlov, V. E. Mandrusov, B. S. Cherepanov, and I. M. Chernyshev. 19(1), 103–4 (Jul. 1974); CPM-7407X1615

82. PHYSICAL CHEMISTRY

82.30.– Chemical reactions

Quenching in the CF_3I photodissociation laser —G. A. Skorobogatov, V. M. Tret'yak, and V. S. Komarov. 19(4), 495–8 (Oct. 1974); CPM-7412X0279

Formation of molecular ions in an alkali discharge —V. N. Paslen and A. M. Przhonskii. 19(5), 705–6 (Nov. 1974); CPM-7501X0499

Gas polymerization wave excited by monochromatic light —A. I. Plis and V. A. Shcheglov. 19(9), 1262–3 (Mar. 1975); CPM-7505X0684

82.50.– Photochemistry and radiation chemistry

Photochemical waves in a medium with a branch-chain conversion mechanism —A. N. Oraevskii, V. P. Pimenov, and V. A. Shcheglov. 19(6), 782–6 (Dec. 1974); CPM-7501X0782

Gas polymerization wave excited by monochromatic light —A. I. Plis and V. A. Shcheglov. 19(9), 1262–3 (Mar. 1975); CPM-7505X0684

Radiation yield of ions in liquid dielectrics as a function of temperature and radiation energy —V. I. Ivanov, E. D. Kleshchenko, Yu. P. Sukhanovskii, and V. V. Frolov. 19(11), 1468–70 (May 1975); CPM-7506X1222

Steady-state electron density in photoionizion of aerosol particles —G. V. Karachevtsev and A. A. Fridman. 19(11), 1471–3 (May 1975); CPM-7506X1225

82.65.– Surface processes

Transient molecular effusion characteristics —Yu. N. Lyubitov and V. Z. Belen'kii. 19(4), 519–22 (Oct. 1974); CPM-7412X0303

Method for studying gas creep along a solid surface —B. M. Markeev. 19(5), 700–1 (Nov. 1974); CPM-7501X0494

Atomic recombination on a solid surface —V. P. Pinchuk, A. N. Gorban', and V. G. Kornich. 19(6), 808–10 (Dec. 1974); CPM-7501X0808

Adsorption of bismuth on tungsten. I. Steady-state processes —M. A. Mittsev. 19(6), 811–4 (Dec. 1974); CPM-7501X0811

Effects of cleaning on adsorption by germanium single crystals —Yu. I. Belyakov, M. P. Volkov, and T. N. Kompaniets. 19(6), 815–6 (Dec. 1974); CPM-7501X0815

Effect of the adsorption rate on the diffusion of deuterium through nickel —Yu. I. Belyakov, Yu. I. Zvezdin, A. A. Kurdyumov, and G. G. Nevdakha. 19(7), 956–8 (Jan. 1975); CPM-7503X0844

Titanium adsorption on tungsten —Yu. K. Ustinov and S. V. Fedichev. 19(8), 1118–9 (Feb. 1975); CPM-7504X1542

Recent developments in surface ionization (review) —É. Ya. Zandberg. 19(9), 1133–44 (Mar. 1975); CPM-7505X0555

Surface evaporation of a solid transparent dielectric under the action of laser radiation —A. M. Bonch-Bruevich, Ya. A. Imas, A. A. Kovalev, P. S. Kondratenko, and B. I. Makshantsev. 19(11), 1474–6 (May 1975); CPM-7506X1228

82.80.– Chemical analysis and related physical methods of analysis

Line shape of a quadrupole mass spectrometer —G. I. Slobodenyuk. 19(2), 292–3 (Aug. 1974); CPM-7408X1556

Formation of molecular ions in an alkali discharge —V. N. Paslen and A. M. Przhonskii. 19(5), 705–6 (Nov. 1974); CPM-7501X0499

Mass spectrum of secondary ions ejected from the surface of a single crystal of gallium arsenide by argon ions —A. G. Koval', V. V. Bobkov, Yu. A. Klimovskii, S. S. Strel'chenko, V. V. Shubina, V. V. Lebedev, and Ya. M. Fogel'. 19(12), 1587–9 (Jun. 1975); CPM-7508X0461

Neutral particles from the interaction of laser radiation with a solid target —Yu. A. Bykovskii, N. M. Vasil'ev, I. D. Laptev, and V. N. Nevolin. 19(12), 1635 (Jun. 1975); CPM-7508X0509

82.90.+ Other topics in physical chemistry

Thermophoresis and diffusophoresis of small, volatile aerosol particles —Yu. I. Yalamov and E. R. Shchukin. 19(2), 278–9 (Aug. 1974); CPM-7408X1542

Possible electrohydrodynamic effects in electrolytes —E. Z. Gak, É. Kh. Rokhinson, and N. F. Bondarenko. 19(5), 676–7 (Nov. 1974); CPM-7501X0470

Vaporization and boiling of liquid metal in an exploding wire —M. M. Martynyuk. 19(6), 793–7 (Dec. 1974); CPM-7501X0793

Approximate similarity relations in the electrical explosions of underwater conductors —E. V. Krivitskii and V. K. Sholom. 19(6), 798–801 (Dec. 1974); CPM-7501X0798

Steady-state electron density in photoionizion of aerosol particles —G. V. Karachevtsev and A. A. Fridman. 19(11), 1471–3 (May 1975); CPM-7506X1225

84. ELECTROMAGNETIC TECHNOLOGY

84.30.– Electronic circuits

Nanosecond x-ray pulses —G. A. Mesyats. 19(7), 948–51 (Jan. 1975); CPM-7503X0836

Explosion driven magnetic generator with a matched inductive load —L. S. Gerasimov. 19(9), 1226–30 (Mar. 1975); CPM-7505X0648

84.40.– Antennas, transmission lines, and propagation

Round metal–optical waveguide filled with a two–layer dielectric —V. A. Pruzhanovskii. 19(1), 3–8 (Jul. 1974); CPM-7407X1515

Differential electromagnetic characteristics at the interface between ice and water in the ocean —V. V. Bogorodskii and V. P. Tripol'nikov. 19(4), 526–8 (Oct. 1974); CPM-7412X0310

Diffraction of a plane electromagnetic wave by a conducting plane with a projection —A. A. Zilbergleit. 19(4), 531–2 (Oct. 1974); CPM-7412X0315

Reflection of electromagnetic waves by a moving plasma —V. I. Miroshnichenko. 19(4), 533–4 (Oct. 1974); CPM-7412X0317

Two–dimensional diffraction on a system of straight segments (shields) —G. A. Grinberg. 19(5), 581–5 (Nov. 1974); CPM-7501X0375

Cerenkov instabilities of a relativistic beam in a periodic plasma–filled waveguide —V. I. Kurilko, Yu. V. Tkach, and V. A. Shendrik. 19 (5), 607–11 (Nov. 1974); CPM-7501X0401

Launching and propagation of regular nonlinear waves in an anisotropic plasma–filled waveguide —V. I. Kurilko, A. P. Tols–toluzhskii, and Ya. B. Fainberg. 19(5), 622–7 (Nov. 1974); CPM-7501X0416

Phase motion of particles in an accelerator with an azimuthally varying electric field —M. F. Vorogushin and V. I. Petrunin. 19(7), 926–9 (Jan. 1975); CPM-7503X0814

Parametric interaction of a charged particle beam with a periodic system —V. I. Koroza and E. S. Sukhovskii. 19(8), 1020–4 (Feb. 1975); CPM-7504X1444

84.60.– Direct energy conversion and energy storage

Inductive energy storage in pulsed accelerators —V. A. Glukhikh, O. A. Gusev, E. G. Komar, and M. P. Svin'in. 19(5), 660–1 (Nov. 1974); CPM-7501X0454

Shaping of voltage pulses by discharging an inductive storage bank with a charged–particle beam —O. A. Gusev, E. G. Komar, V. B. Markov, and E. M. Mellekh. 19(5), 662–3 (Nov. 1974); CPM-7501X0456

Explosion driven magnetic generator with a matched inductive load —L. S. Gerasimov. 19(9), 1226–30 (Mar. 1975); CPM-7505X0648

Dependence of the basic parameters of $Al_xGa_{1-x}As$—GaAs solar converters on temperature and optical intensity —E. B. Vinogradova, M. B. Kagan, N. S. Koroleva, T. L. Lyubashevskaya, and T. A. Nuller. 19(10), 1378–81 (Apr. 1975); CPM-7506X0312

84.70.+ High-current and high-voltage technology

Switching characteristis of a discharge in water —V. M. Kuleshov, S. L. Nedoseev, V. P. Smirnov, and A. M. Spektor. 19(1), 150–1 (Jul. 1974); CPM-7407X1662

Electron energy spectrum in a high-current vacuum diode —S. P. Bugaev, V. I. Koshelev, and M. N. Timofeev. 19(9), 1193–5 (Mar. 1975); CPM-7505X0615

Hydrogen-ion mobility in a high-pressure unipolar corona —A. G. Lyapin. 19(9), 1236–8 (Mar. 1975); CPM-7505X0658

84.80.– Particle beams and particle optics

Focusing of an astigmatic beam by a doublet and a symmetric triplet of quadrupole lenses —V. I. Chetvertkov. 19(1), 1–2 (Jul. 1974); CPM-7407X1513

Energy resolution of quadrupole lenses for charged–particle beams —V. S. Siksin. 19(3), 301–7 (Sep. 1974); CPM-7412X0987

Beam focusing in an accelerator with inductive energy storage —V. A. Glukhikh, O. A. Gusev, E. G. Komar, V. S. Kuznetsov, M. P. Svin'in, and R. P. Fidel'skaya. 19(3), 366–7 (Sep. 1974); CPM-7412X1052

Symmetric multielectrode tubular electrostatic lenses —L. G. Glikman, V. M. Kel'man, and M. Sh. Nurmanov. 19(5), 680–2 (Nov. 1974); CPM-7501X0474

Maximum current of a beam with finite phase volume —G. I. Trubnikov and V. S. Kuznetsov. 19(6), 715–6 (Dec. 1974); CPM-7501X0715

Azimuthal and vertical motion in an accelerator with azimuthally varying electric field —M. F. Vorogushin and V. I. Petrunin. 19(6), 770–2 (Dec. 1974); CPM-7501X0770

Angular aberration corrector in a cylindrical mirror analyzer —V. V. Zashkavara and V. F. Tarasov. 19(6), 841–2 (Dec. 1974); CPM-7501X0841

Radiation from a charged particle moving close to an anisotropic dielectric —A. I. Plis and N. M. Safikhodzhaev. 19(7), 865–7 (Jan. 1975); CPM-7503X0753

Spectral narrowing of a single-mode beam oscillator —V. A. Buts and V. I. Kurilko. 19(11), 1494–5 (May 1975); CPM-7506X1248

84.80.D Electron beams and electron optics

Parametric instability of an electron beam in a magnetic field —A. I. Pasynok and N. S. Repalov. 19(2), 177–80 (Aug. 1974); CPM-7408X1441

High–current pulsed electron accelerator with an annular beam —M. I. Avramenko, V. A. Glukhikh, O. A. Gusev, E. G. Komar, O. L. Komarov, V. S. Kuznetsov, A. S. Perlin, and M. P. Svin'in. 19(3), 368–70 (Sep. 1974); CPM-7412X1054

Transmission of a high–current relativistic beam through a gas —Yu. V. Tkach, I. I. Magda, G. V. Skachek, S. S. Pushkarev, and I. P. Panchenko. 19(3), 412–3 (Sep. 1974); CPM-7412X1098

Energy input in electrical ionization lasers —Yu. I. Bychkov, Yu. D. Korolev, Yu. A. Kurbatov, and G. A. Mesyats. 19(4), 499–502 (Oct. 1974); CPM-7412X0283

Characteristics of the electrical ionization CO_2 laser —Yu. I. Bychkov, Yu. A. Kurbatov, and V. V. Savin. 19(4), 506–8 (Oct. 1974); CPM-7412X0290

Electrostatic analyzer for wide beams —V. G. Kovalenko and B. V. Polenov. 19(4), 561–2 (Oct. 1974); CPM-7412X0345

Low–voltage gun with a resonator for formation of electron bunches in a linear accelerator —V. A. Boiko, R. M. Voronkov, and V. A. Danilichev. 19(4), 569–71 (Oct. 1974); CPM-7412X0353

Parametric excitation of surface waves in a spatially modulated electron beam —A. I. Pasynok and N. S. Repalov. 19(4), 572–3 (Oct. 1974); CPM-7412X0356

Theory of the cathode lens. III. Derivation of equations for composite cathode lenses —V. M. Kel'man, A. A. Sapargaliev, and E. M. Yakushev. 19(5), 592–6 (Nov. 1974); CPM-7501X0386

Theory of the cathode lens. IV. Aberrations of composite cathode lens —V. M. Kel'man, A. A. Sapargaliev, and E. M. Yakushev. 19(5), 597–9 (Nov. 1974); CPM-7501X0391

Cerenkov instabilities of a relativistic beam in a periodic plasma–filled waveguide —V. I. Kurilko, Yu. V. Tkach, and V. A. Shendrik. 19 (5), 607–11 (Nov. 1974); CPM-7501X0401

Electron–scanning transformation of the potential distribution on an electrostatic target —V. L. Lentsman. 19(5), 678–9 (Nov. 1974); CPM-7501X0472

Aperiodic instability in a plasma gap with external feedback —A. N. Igritskii. 19(6), 719–21 (Dec. 1974); CPM-7501X0719
Spatial and energy parameters of the relativistic electron beam of the Rius-5 accelerator —A. T. Altyntsev and V. I. Koroteev. 19(6), 773–4 (Dec. 1974); CPM-7501X0773
Estimate of the angular divergence in intense electron beams —V. S. Kuznetsov, Yu. P. Vakhrushin, O. L. Komarov, and R. P. Fidel'skaya. 19(7), 868–70 (Jan. 1975); CPM-7503X0756
Parametric instability of a spatially moderated electron beam in a magnetic field —N. S. Repalov and V. F. Tyrnov. 19(7), 871–3 (Jan. 1975); CPM-7503X0759
Control of output energy in linear electron accelerators —V. N. Golovin and N. P. Sobenin. 19(7), 932–4 (Jan. 1975); CPM-7503X0820
Ion focusing of an electron beam in deep melting of a metal —M. D. Gabovich, V. P. Kovalenko, O. A. Metallov, O. K. Nazarenko, and S. K. Pats'ora. 19(7), 973–4 (Jan. 1975); CPM-7503X0861
Stability of the diode —V. A. Buts. 19(8), 1034–7 (Feb. 1975); CPM-7504X1458
Self-excited waveguide buncher —N. M. Gavrilov and A. V. Nesterovich. 19(8), 1085–6 (Feb. 1975); CPM-7504X1509
Self-acceleration of an intense electron beam —I. A. Grishaev, A. N. Dedik, V. V. Zakutin, I. I. Magda, Yu. V. Tkach, and A. M. Shenderovich. 19(8), 1087–9 (Feb. 1975); CPM-7504X1511
Magnetic-field transport of a high-current electron beam —A. V. Agafonov, V. S. Voronin, A. N. Lebedev, and K. N. Pazin. 19(9), 1188–92 (Mar. 1975); CPM-7505X0610
Electron energy spectrum in a high-current vacuum diode —S. P. Bugaev, V. I. Koshelev, and M. N. Timofeev. 19(9), 1193–5 (Mar. 1975); CPM-7505X0615
Multiple scattering of a focused beam of monoenergetic electrons —G. N. Vyalov. 19(9), 1216–8 (Mar. 1975); CPM-7505X0638
Luminosity of a cylindrical spectrometer with a small off-axis source —V. V. Zashkvara. 19(9), 1264–5 (Mar. 1975); CPM-7505X0686
Fifth-order spherical aberration in focusing and correcting quadrupole—octupole systems —Ya. G. Lyubchik and T. Ya. Fishkova. 19 (11), 1403–7 (May 1975); CPM-7506X1157
Axially symmetric neutralized electron beam —G. N. Vyalov, V. N. Evteev, Yu. M. Zolotaikin, and K. N. Ul'yanov. 19(11), 1414–7 (May 1975); CPM-7506X1168
Stabilization of two-stream instabilities —V. A. Buts. 19(11), 1496–7 (May 1975); CPM-7506X1250
Method for optical modulation of an electron beam —V. I. Sotnikov. 19(11), 1510–1 (May 1975); CPM-7506X1264
Wave excitation at half the gyrofrequency in counterstreaming electron beams —A. P. Timoshenko, D. V. Iremashvili, and Yu. K. Udovichenko. 19(12), 1584–6 (Jun. 1975); CPM-7508X0458
Electron-optical properties of postdeflection quadrupole lenses —T. Ya. Fishkova. 19(12), 1618–9 (Jun. 1975); CPM-7508X0492
Reflection of a high-current relativistic electron beam from a conducting surface —A. N. Didenko, A. I. Ryabchikov, V. A. Tuzov, and Yu. P. Usov. 19(12), 1625–6 (Jun. 1975); CPM-7508X0499
Coherent phase oscillations of electrons in a synchrotron —M. M. Nikitin. 19(12), 1633–4 (Jun. 1975); CPM-7508X0507

84.80.G Ion beams and ion optics

Production of an ion beam by a magnetic system with opposed fields —V. B. Glasko, A. G. Sveshnikov, and N. N. Semashko. 19(2), 201–5 (Aug. 1974); CPM-7408X1465
Gas-kinetic removal of neutral molecules from an ion beam —V. P. Ivanov. 19(2), 239–42 (Aug. 1974); CPM-7408X1503
Focusing of a neutralized ion beam by a plasma-optics system —I. I. Demidenko, N. S. Lomino, A. I. Morozov, and V. G. Padalka. 19 (3), 347–50 (Sep. 1974); CPM-7412X1033
Energy dependence of the focusing of ions by crystals —E. S. Mashkova, V. A. Molchanova, and A. D. Pavlova. 19(4), 540 (Oct. 1974); CPM-7412X0324
Gas focusing of a negative-ion beam —M. D. Gabovich, A. P. Naida, I. M. Protsenko, L. S. Simonenko, and I. A. Soloshenko. 19(4), 546–7 (Oct. 1974); CPM-7412X0330
Electrostatic analyzer for wide beams —V. G. Kovalenko and B. V. Polenov. 19(4), 561–2 (Oct. 1974); CPM-7412X0345
Correction of third-order angular aberration in a system with two electrostatic mirrors —V. V. Zashkvara. 19(7), 961–2 (Jan. 1975); CPM-7503X0849
Elimination of spherical aberration in an axial plasma lens —S. V. Lebedev and A. I. Morozov. 19(7), 966 (Jan. 1975); CPM-7503X0854
Achromatic plasma-lens system —A. I. Morozov and S. V. Lebedev. 19(7), 967 (Jan. 1975); CPM-7503X0855
Multiple-aperture ion source for electromagnetic mass separator —S. V. Lebedev. 19(7), 968 (Jan. 1975); CPM-7503X0856
Parametric interaction of a charged particle beam with a periodic system —V. I. Koroza and E. S. Sukhovskii. 19(8), 1020–4 (Feb. 1975); CPM-7504X1444
Parallel-plate capacitor as a charged-particle spectrometer —Yu. D. Kornyushkin. 19(8), 1110–2 (Feb. 1975); CPM-7504X1534
Double focusing in a system of $1/r$ electric and magnetic fields —V. V. Zashkvara and V. N. Demin. 19(9), 1219–20 (Mar. 1975); CPM-7505X0641
Graphical methods for constructing trajectories of small particles in electrostatic fields —N. I. Shtepa. 19(9), 1253–5 (Mar. 1975); CPM-7505X0675
Plasma synthesis by injection of an electron beam through an ion source —V. F. Virko, M. D. Gabovich, G. S. Kirichenko, and O. K. Nazarenko. 19(11), 1418–20 (May 1975); CPM-7506X1172
Ion-optical system for shaping high-current ion beams —S. D. Grishin, V. F. Kuzovlev, R. V. Orlov, and S. N. Ogorodnikov. 19 (11), 1462–4 (May 1975); CPM-7506X1216
Loss of neutralization for a stable neutralized ion beam —M. D. Gabovich. 19(11), 1502–3 (May 1975); CPM-7506X1256
Stigmatic sectored magnetic analyzer for a multiple-beam mass spectrometer —G. Kh. Chedzhemov. 19(11), 1516–7 (May 1975); CPM-7506X1270

84.90.+ Other topics in electromagnetic technology

Two-spin oscillator with optical orientation of electrons and nuclei —R. A. Zhitnikov and V. V. Semenov. 19(1), 105–9 (Jul. 1974); CPM-7407X1617
Dynamic magnetic-resonance phenomena —P. S. Kuts and V. S. Mel'nik. 19(1), 110–4 (Jul. 1974); CPM-7407X1622
Shot noise in a thermionic cathode —A. F. Golubentsev and A. S. Shapovalov. 19(10), 1345–6 (Apr. 1975); CPM-7506X0279

85. ELECTRICAL AND MAGNETIC DEVICES

85.10.- Electron tubes

Effect of electron-atom collisions on electron motion in a gas diode —V. I. Babanin and A. Ya. Énder. 19(1), 60–5 (Jul. 1974); CPM-7407X1572
Perveance of a vacuum with a point cathode —S. P. Bugaev, E. A. Litvinov, V. V. Lopatin, and G. A. Mesyats. 19(1), 88–90 (Jul. 1974); CPM-7407X1600
Peak current in a cold-cathode magnetron —I. M. Vigdorchik and V. P. Timofeev. 19(1), 142–3 (Jul. 1974); CPM-7407X1654
End current in a magnetron with a secondary-emission cathode —G. G. Sominskii, S. A. Fridrikhov, O. Yu. Tsybin, and A. P. Karizhskii. 19(3), 378–81 (Sep. 1974); CPM-7412X1064
Electron-scanning transformation of the potential distribution on an electrostatic target —V. L. Lentsman. 19(5), 678–9 (Nov. 1974); CPM-7501X0472
Evaluation of charge distribution in a crossed-field device from ion bombardment of the cathode —V. I. Malyugin and G. G. Sominskii. 19(7), 942–5 (Jan. 1975); CPM-7503X0830
Stability of the diode —V. A. Buts. 19(8), 1034–7 (Feb. 1975); CPM-7504X1458
Secondary-electron energy in a resonance discharge in a three-electrode system —Yu. A. Kulikov, V. V. Ogienko, and Yu. M. Trifonov. 19(8), 1090–2 (Feb. 1975); CPM-7504X1514
Microcells in cold cathodes —N. P. Kozlov, A. A. Lyapin, and V. I. Khvesyuk. 19(8), 1093–5 (Feb. 1975); CPM-7504X1517
Numerical experiments on electron bombardment in crossed fields —P. V. Romanov and A. S. Roshal'. 19(9), 1221–3 (Mar. 1975); CPM-7505X0643

85.70.– Magnetic devices

Two–section solenoid with internal "equally–loaded" section; power as a function of the length of the internal section —G. S. Veisig, A. P. Doroshenko, and P. P. Rybin. **19**(3), 416–8 (Sep. 1974); CPM-7412X1102

Two–omegatron study of the pumping characteristics of an NÉM–300 magnetic discharge pump for a mixture of gases —M. K. Bulgakov and V. G. Rogozinskii. **19**(3), 427–8 (Sep. 1974); CPM-7412X1113

Shielding properties of superconducting shields —S. I. Bondarenko, S. S. Vinogradov, G. A. Gogadze, S. S. Perepelkin, and V. I. Sheremet. **19**(6), 824–8 (Dec. 1974); CPM-7501X0824

Distortion of single-turn solenoids in ultrahigh magnetic fields —G. A. Shneerson. **19**(10), 1371–7 (Apr. 1975); CPM-7506X0305

85.90.+ Other topics in electrical and magnetic devices

Electron repulsion in a time–resolving electron–optical image converter —M. M. Butslov and M. E. Gertsenshtein. **19**(1), 129–30 (Jul. 1974); CPM-7407X1641

Strobe unit for measuring luminescence in the range 10^{-7}–$2\cdot10^{-10}$ sec —V. A. Bonch–Bruevich and N. A. Tolstoi. **19**(2), 284–6 (Aug. 1974); CPM-7408X1548

Optimization of the paraxial asymptotic electric field in electron–optical systems —V. E. Ginzburg and V. N. Danilov. **19** (3), 407–9 (Sep. 1974); CPM-7412X1093

Upper and lower limits on the capacitance of a plane capacitor —R. F. Fikhmanas and P. Sh. Fridberg. **19**(5), 683–4 (Nov. 1974); CPM-7501X0477

Preservation of semiconductor field–emission cathodes —N. V. Egorov, G. N. Fursei, and M. K. El'Nimr. **19**(5), 709 (Nov. 1974); CPM-7501X0503

Vaporization and boiling of liquid metal in an exploding wire —M. M. Martynyuk. **19**(6), 793–7 (Dec. 1974); CPM-7501X0793

Approximate similarity relations in the electrical explosions of underwater conductors —E. V. Krivitskii and V. K. Sholom. **19**(6), 798–801 (Dec. 1974); CPM-7501X0798

Thermal conditions for a sandwich cold cathode —F. M. Benson, P. E. Troyan, and Yu. B. Yankelevich. **19**(7), 946–7 (Jan. 1975); CPM-7503X0834

Superconducting magnetic shields —S. I. Bondarenko and V. I. Sheremet. **19**(7), 952–5 (Jan. 1975); CPM-7503X0840

Electrical characteristics of underwater exploding wires —V. K. Sholom, E. V. Krivitskii, and V. P. Litvinenko. **19**(10), 1329–31 (Apr. 1975); CPM-7506X0263

91. GEOPHYSICS AND EARTH SCIENCES

Narrow–band decimeter radiation from lighting —E. L. Kosarev and Yu. G. Serezhkin. **19**(2), 229–33 (Aug. 1974); CPM-7408X1493

Radar sounding of sea ice —V. V. Bogorodskii and V. P. Tripol'nikov. **19**(3), 414–5 (Sep. 1974); CPM-7412X1100

Differential electromagnetic characteristics at the interface between ice and water in the ocean —V. V. Bogorodskii and V. P. Tripol'nikov. **19**(4), 526–8 (Oct. 1974); CPM-7412X0310

Evolution of monochromatic whistler and plasma–wave packets in a collisionless plasma —Ya. N. Istomin. **19**(4), 529–30 (Oct. 1974); CPM-7412X0313

Gas cooling in transmission of high–power CO_2 laser radiation through the atmosphere —B. F. Gordiets, A. I. Osipov, and R. V. Khokhlov. **19**(5), 669–72 (Nov. 1974); CPM-7501X0463

AUTHOR INDEX TO VOLUME 19

Papers are arranged in ascending page number order.

A

Abdrashitova, D. Kh.—Efficient ion source —D. Kh. Abdrashitova, V. G. Babaev, and M. B. Guseva. 19(2), 264–6 (Aug. 1974); CPM-7408X1528

Abdulloev, Kh. O.—Excitation of acoustic waves by ion-acoustic turbulence —Kh. O. Abdulloev, F. Kh. Khakimov, and V. G. Makhan'kov. 19(4), 441–5 (Oct. 1974); CPM-7412X0225

Abramov, Yu. Yu.—Model for the low-voltage arc. I. Stationary solution —Yu. Yu. Abramov and G. G. Gladush. 19(6), 745–7 (Dec. 1974); CPM-7501X0745

—Model for the low-voltage arc. II. Stability —Yu. Yu. Abramov and G. G. Gladush. 19(6), 748–50 (Dec. 1974); CPM-7501X0748

Abroyan, M. A.—Electron energy distribution in a constricted, low-pressure hydrogen discharge —M. A. Abroyan, Yu. M. Kagan, N. B. Kolokolov, and B. P. Lavrov. 19(11), 1492–3 (May 1975); CPM-7506X1246

Agafonov, A. V.—Magnetic-field transport of a high-current electron beam —A. V. Agafonov, V. S. Voronin, A. N. Lebedev, and K. N. Pazin. 19(9), 1188–92 (Mar. 1975); CPM-7505X0610

Agafonova, E. N.—Motion of charged particles in a nonneutral plasma —E. N. Agafonova and L. I. Grechikhin. 19(11), 1488–9 (May 1975); CPM-7506X1242

Akin'shin, V. D.—Flow of low-density gases in a capillary grid —B. T. Porodnov, V. D. Akin'shin, V. I. Kichaev, S. F. Borisov, and P. E. Suetin. 19(4), 515–8 (Oct. 1974); CPM-7412X0299

Al'bikov, Z. A.—Acceleration of plasma electrons in strong electric fields —Z. A. Al'bikov, M. I. Ivanov, V. I. Kazacha, O. V. Kozlov, V. D. Rusanov, and S. S. Sobolev. 19(11), 1498–9 (May 1975); CPM-7506X1252

Aleksandrov, A. F.—Dynamics and emission of coaxial plasma shells in air —A. F. Aleksandrov, V. V. Perebeinos, A. T. Savichev, and I. B. Timofeev. 19(1), 38–42 (Jul. 1974); CPM-7407X1550

—Radiating discharges confined by walls —A. F. Aleksandrov, I. S. Marshak, and A. A. Rukhadze. 19(3), 308–14 (Sep. 1974); CPM-7412X0994

—Initial stage of a high-current discharge in air —A. F. Aleksandrov, V. V. Perebeinos, A. T. Savichev, and I. B. Timofeev. 19(11), 1490–1 (May 1975); CPM-7506X1244

Aleksandrov, M. L.—Simulation of ion scattering on diatomic molecules —M. L. Aleksandrov, N. S. Pliss, and A. P. Shcherbakov. 19(3), 394–5 (Sep. 1974); CPM-7412X1080

—Monte Carlo analysis of ion scattering in a mass spectrometer —M. L. Aleksandrov, L. N. Gall', and N. S. Pliss. 19(6), 817–9 (Dec. 1974); CPM-7501X0817

Aleksandrova, A. A.—Diffraction of electromagnetic waves by a dielectric wedge —A. A. Aleksandrova and N. A. Khizhnyak. 19 (11), 1385–9 (May 1975); CPM-7506X1139

Aleksin, V. F.—Diffusion of quasistationary helical magnetic fields into the interior of cylindrical chambers. II. —V. F. Aleksin and S. S. Romanov. 19(9), 1171–3 (Mar. 1975); CPM-7505X0593

Alferov, Zh. I.—Time characteristics of the near radiation field of the injection laser —Zh. I. Alferov, V. N. Deryagin, L. E. Marasin, Yu. V. Popov, and E. L. Portnoi. 19(4), 548 (Oct. 1974); CPM-7412X0332

Alkhazov, G. D.—Continuous electron acceleration in a gas discharge —G. D. Alkhazov. 19(5), 658–9 (Nov. 1974); CPM-7501X0452

Al'pert, Ya. L.—Rotation of Poynting vector for ultralow-frequency ion waves in an inhomogeneous plasma —Ya. L. Al'pert and R. N. Kaufman. 19(12), 1519–21 (Jun. 1975); CPM-7508X0393

Altyntsev, A. T.—Spatial and energy parameters of the relativistic electron beam of the Rius-5 accelerator —A. T. Altyntsev and V. I. Koroteev. 19(6), 773–4 (Dec. 1974); CPM-7501X0773

—Connection of magnetic lines of force in a neutral layer —A. T. Altyntsev and V. I. Krasov. 19(12), 1639–40 (Jun. 1975); CPM-7508X0513

Andreev, A. D.—Direct current in a metal—selenium—metal structure boundary by an rf plasma —A. D. Andreev and S. I. Lubinskii. 19(12), 1606–7 (Jun. 1975); CPM-7508X0480

Andreev, A. P.—Rate for evaporation of a liquid into vacuum —A. P. Andreev and M. A. Gurevich. 19(3), 396–401 (Sep. 1974); CPM-7412X1082

Andreev, P. A.—Thermoacoustic waves in conducting gases and liquids —P. A. Andreev. 19(6), 845–6 (Dec. 1974); CPM-7501X0845

—Acousto-electric waves in conducting media —P. A. Andreev. 19 (8), 1001–4 (Feb. 1975); CPM-7504X1425

Andreeva, E. Yu.—Frequency locking in a 3.39μ laser —E. Yu. Andreeva, S. N. Gulyaev, and D. K. Terekhin. 19(12), 1620–1 (Jun. 1975); CPM-7508X0494

Antimirov, M. Ya.—Nonstationary magnetohydrodynamic flow and wave propagation —M. Ya. Antimirov and Yu. Ya. Boguslavskii. 19(7), 878–9 (Jan. 1975); CPM-7503X0766

Antsupov, A. V.—Properties of underexpanded and overexpanded supersonic gas jets —A. V. Antsupov. 19(2), 234–8 (Aug. 1974); CPM-7408X1498

Arakelyan, S. M.—Direct and cascade four-photon parametric scattering of light in $LiIO_3$ crystals —S. M. Arakelyan, V. G. Tunkin, A. I. Kholodnykh, and A. S. Chirkin. 19(6), 787–92 (Dec. 1974); CPM-7501X0787

Aref'ev, V. I.—Plasma acceleration in crossed electric and magnetic fields —V. I. Aref'ev. 19(4), 446–54 (Oct. 1974); CPM-7412X0230

—Anomalous resistivity of transverse plasma current at electron-cyclotron harmonics —V. I. Aref'ev and A. A. Chernov. 19(12), 1522–8 (Jun. 1975); CPM-7508X0396

Arsenin, V. V.—Stabilization of the major radius of toroidal pinch by a feedback system —V. V. Arsenin. 19(7), 895–7 (Jan. 1975); CPM-7503X0783

Artamonov, O. M.—Energy losses of slow electrons reflected from molybdenum and tungsten single crystals —O. M. Artamonov, B. B. Bolotov, and M. V. Kremkov. 19(8), 1103–4 (Feb. 1975); CPM-7504X1527

Artemov, A. D.—Proton extraction from the 70-GeV accelerator for the Ludmila liquid-hydrogen chamber (extraction system S) —A. A. Aseev, A. I. Drozhdin, B. A. Zelenov, É. A. Merker, L. L. Moizhes, K. P. Myznikov, A. A. Roshchin, V. M. Tatarenko, M. A. Kholodenko, A. D. Artemov, L. N. Vaulin, V. I. Gordin, I. I. Kovalevskii, V. N. Rozhkov, M. M. Suvorov, A. S. Sudarushkin, and V. I. Chuiko. 19(1), 70–6 (Jul. 1974); CPM-7407X1582

Aseev, A. A.—Proton extraction from the 70-GeV accelerator for the Ludmila liquid-hydrogen chamber (extraction system S) —A. A. Aseev, A. I. Drozhdin, B. A. Zelenov, É. A. Merker, L. L. Moizhes, K. P. Myznikov, A. A. Roshchin, V. M. Tatarenko, M. A. Kholodenko, A. D. Artemov, L. N. Vaulin, V. I. Gordin, I. I. Kovalevskii, V. N. Rozhkov, M. M. Suvorov, A. S. Sudarushkin, and V. I. Chuiko. 19(1), 70–6 (Jul. 1974); CPM-7407X1582

Asvadurov, K. D.—Electron energy distribution in helium, nitrogen, and their mixtures —K. D. Asvadurov, I. A. Vasil'eva, and V. M. Torchinskii. 19(3), 354–7 (Sep. 1974); CPM-7412X1040

Avilov, É. A.—Electrical strength of nitrogen and hyrodgen at high pressures —É. A. Avilov and N. V. Belkin. 19(12), 1631–2 (Jun. 1975); CPM-7508X0505

Avramenko, M. I.—High-current pulsed electron accelerator with an annular beam —M. I. Avramenko, V. A. Glukhikh, O. A. Gusev, E. G. Komar, O. L. Komarov, V. S. Kuznetsov, A. S. Perlin, and M. P. Svin'in. 19(3), 368–70 (Sep. 1974); CPM-7412X1054

B

Babaev, V. G.—Efficient ion source —D. Kh. Abdrashitova, V. G. Babaev, and M. B. Guseva. 19(2), 264–6 (Aug. 1974); CPM-7408X1528

Babanin, V. I.—Effect of electron-atom collisions on electron motion in a gas diode —V. I. Babanin and A. Ya. Énder. 19(1), 60–5 (Jul. 1974); CPM-7407X1572

Babich, L. P.—Stability of field-emission beams in nonsecond discharges —L. P. Babich. 19(3), 371–2 (Sep. 1974); CPM-7412X1057

—Optical radiation from nanosecond discharges in dense gases —L. P. Babich. 19(3), 419–20 (Sep. 1974); CPM-7412X1105

—Stochastic acceleration of electrons in nanosecond discharges —L. P. Babich. 19(9), 1154–6 (Mar. 1975); CPM-7505X0576

Baikov, I. S.—Anomalous ion heating in a parametrically unstable plasma —I. S. Baikov and V. P. Silin. 19(12), 1529–33 (Jun. 1975); CPM-7508X0403

Bakanov, S. P.—State of a gas moving near a solid surface —S. P. Bakanov and B. M. Markeev. 19(10), 1293–4 (Apr. 1975); CPM-7506X0227

—Certain integral relations in the kinetic theory of gases —S. P. Bakanov. 19(12), 1636–8 (Jun. 1975); CPM-7508X0510

Bakhtiyarov, R. S.—Electron-microscope and x-ray study of thermionic emitters made from Mo–Pt alloys —B. B. Shishkin and R. S. Bakhtiyarov. 19(2), 243–50 (Aug. 1974); CPM-7408X1507

Baksht, F. G.—Theory of the low-voltage arc in a narrow gap —F. G. Baksht, A. A. Kostin, and V. A. Nemchinskii. 19(5), 654–7 (Nov. 1974); CPM-7501X0448

—Atomic density in the low-voltage arc in a cesium diode —F. G. Baksht, A. A. Kostin, Yu. L. Serov, and I. P. Yavor. 19(11), 1424–5 (May 1975); CPM-7506X1178

Balkarei, Yu. I.—Resonant amplification of an image potential by an electromagnetic wave —Yu. I. Balkarei and É. M. É pshtein. 19(6), 843–4 (Dec. 1974); CPM-7501X0843

Baranchuk, N. S.—Physical properties of an electrodeless pulsed discharge in a gas-filled glass cell —Yu. I. Chutov, N. S. Baranchuk, M. R. Lozovich, and V. G. Danilov. 19(2), 224–8 (Aug. 1974); CPM-7408X1488

Barannik, S. I.—Resistance and inductance of a gas arc —S. I. Barannik, S. B. Vasserman, and A. N. Lukin. 19(11), 1449–53 (May 1975); CPM-7506X1203

Baranov, Yu. F.—Generation of drift waves by an rf field near the lower hybrid frequency —Yu. F. Baranov, D. G. Bulyginskii, M. I. Vil'dzhyunas, B. V. Galaktionov, and N. V. Shustova. 19(6), 732–5 (Dec. 1974); CPM-7501X0732

Bardina, N. S.—Thermal effect of continuous laser radiation on optically transparent media —N. S. Bardina, A. I. Portnyagin, M. Yu. Sklyarov, and A. A. Churin. 19(4), 491–4 (Oct. 1974); CPM-7412X0275

Barsegyan, O. A.—Motion of stable aerosol particles —O. A. Barsegyan and Yu. I. Yalamov. 19(11), 1486–7 (May 1975); CPM-7506X1240

Batyrbekov, G. A.—Charge-carrier density of the plasma produced in a Penning mixture by irradiation by uranium fission fragments and reactor radiation —G. A. Batyrbekov, Yu. D. Kuznetsov, and Zh. S. Takibaev. 19(5), 645–6 (Nov. 1974); CPM-7501X0439

Bazilevskaya, T. A.—Conversion of neutral hydrogen into protons in dense plasmas —T. A. Bazilevskaya, L. I. Krupnik, and N. G. Shulika. 19(6), 741–4 (Dec. 1974); CPM-7501X0741

Beilis, I. I.—Analysis of the cathode spot in a vacuum arc —I. I. Beilis. 19(2), 251–6 (Aug. 1974); CPM-7408X1515

—Emission processes at the cathode of an electric arc —I. I. Beilis. 19 (2), 257–60 (Aug. 1974); CPM-7408X1521

Bekmukhambetov, E. S.—Thermal diffusion in a mixture of cesium vapor and helium —E. S. Bekmukhambetov and V. A. Donov. 19 (12), 1627–8 (Jun. 1975); CPM-7508X0501

Belan, N. V.—Breakdown caused by electron bombardment of the surface of an alloy electrode —N. V. Belan, G. I. Kostyuk, and V. A. Pimkin. 19(6), 802–3 (Dec. 1974); CPM-7501X0802

Belen'kii, V. Z.—Transient molecular effusion characteristics —Yu. N. Lyubitov and V. Z. Belen'kii. 19(4), 519–22 (Oct. 1974); CPM-7412X0303

Belkin, N. V.—Electrical strength of nitrogen and hyrodgen at high pressures —É. A. Avilov and N. V. Belkin. 19(12), 1631–2 (Jun. 1975); CPM-7508X0505

Bel'kov, E. P.—Dielectric strength of spark gaps following strong current pulses —E. P. Bel'kov. 19(9), 1210–3 (Mar. 1975); CPM-7505X0632

Belousov, E. V.—Microwave discharge in argon —E. V. Belousov, A. S. Bryukhovetskii, and A. V. Prokopov. 19(1), 53–6 (Jul. 1974); CPM-7407X1565

Belousova, I. M.—Sign of the change in optical path length in a laser interferometer with feedback —I. M. Belousova and A. F. Zapryagaev. 19(6), 829–30 (Dec. 1974); CPM-7501X0829

Belyakov, L. V.—Characteristics of diffraction gratings obtained by photoetching of semiconductor surfaces —L. V. Belyakov, D. N. Goryachev, M. N. Mizerov, and E. L. Portnoi. 19(6), 837–8 (Dec. 1974); CPM-7501X0837

Belyakov, Yu. I.—Effects of cleaning on adsorption by germanium single crystals —Yu. I. Belyakov, M. P. Volkov, and T. N. Kompaniets. 19(6), 815–6 (Dec. 1974); CPM-7501X0815

—Effect of the adsorption rate on the diffusion of deuterium through nickel —Yu. I. Belyakov, Yu. I. Zvezdin, A. A. Kurdyumov, and G. G. Nevdakha. 19(7), 956–8 (Jan. 1975); CPM-7503X0844

Benson, F. M.—Thermal conditions for a sandwich cold cathode —F. M. Benson, P. E. Troyan, and Yu. B. Yankelevich. 19(7), 946–7 (Jan. 1975); CPM-7503X0834

Berezin, A. K.—Interaction of a hollow electron beam with a plasma —N. M. Zemlyanskii, A. K. Berezin, Ya. B. Fainberg, L. I. Bolotin, and S. S. Krivulya. 19(12), 1547–8 (Jun. 1975); CPM-7508X0421

Berkov, V. I.—Radiation energy of a magnetoplasma compressor —V. I. Berkov and A. I. Morozov. 19(2), 220–3 (Aug. 1974); CPM-7408X1484

Berman, G. P.—Nonlinear effects for the "kink" instability in an electron-ion ring —G. P. Berman. 19(10), 1312–6 (Apr. 1975); CPM-7506X0246

Biryukov, A. S.—Kinetics of gasdynamic lasers. Effect of nozzle geometry on inversion —A. S. Biryukov and L. A. Shelepin. 19(6), 775–81 (Dec. 1974); CPM-7501X0775

Blagoev, A. B.—Electron energy distribution in the afterglow. I —A. B. Blagoev, Yu. M. Kagan, N. B. Kolokolov, and R. I. Lyagushchenko. 19(2), 211–4 (Aug. 1974); CPM-7408X1475

—Electron energy distribution in the afterglow. II —A. B. Blagoev, Yu. M. Kagan, N. B. Kolokolov, and R. I. Lyagushchenko. 19(2), 215–9 (Aug. 1974); CPM-7408X1479

Bobkov, V. V.—Mass spectrum of secondary ions ejected from the surface of a single crystal of gallium arsenide by argon ions —A. G. Koval', V. V. Bobkov, Yu. A. Klimovskii, S. S. Strel'chenko, V. V. Shubina, V. V. Lebedev, and Ya. M. Fogel'. 19(12), 1587–9 (Jun. 1975); CPM-7508X0461

Bobrov, Yu. K.—Gasdynamic model of the spark discharge —Yu. K. Bobrov. 19(11), 1442–6 (May 1975); CPM-7506X1196

Bochkova, O. P.—Electron density in an argon afterglow —O. P. Bochkova, R. I. Lyagushchenko, É. A. Sukiasyan, and Yu. A. Tolmachev. 19(4), 475–7 (Oct. 1974); CPM-7412X0259

Boev, A. G.—Effect of ionization and excitation on the penetration of an electromagnetic wave into a weakly ionized plasma —A. G. Boev and A. V. Prokopov. 19(7), 901–4 (Jan. 1975); CPM-7503X0789

Bogdanov, E. V.—Electromagnetic fields outside a synthesized plasma jet —E. V. Bogdanov, G. M. Mantrova, and M. N. Yakovleva. 19(7), 919–21 (Jan. 1975); CPM-7503X0807

Bogdanov, S. V.—Optical methods for studying amplification of elastic surface waves in a stratified system —I. B. Yakovkin, V. V. Petrov, and S. V. Bogdanov. 19(9), 1242–5 (Mar. 1975); CPM-7505X0664

Bogomolov, Yu. V.—Kinetic theory for wave reflection from a moving plasma —Yu. V. Bogomolov. 19(2), 190–2 (Aug. 1974); CPM-7408X1454

Bogorodskii, V. V.—Radar sounding of sea ice —V. V. Bogorodskii and V. P. Tripol'nikov. 19(3), 414–5 (Sep. 1974); CPM-7412X1100

—Differential electromagnetic characteristics at the interface between ice and water in the ocean —V. V. Bogorodskii and V. P. Tripol'nikov. 19(4), 526–8 (Oct. 1974); CPM-7412X0310

Boguslavskii, Yu. Ya.—Nonstationary magnetohydrodynamic flow and wave propagation —M. Ya. Antimirov and Yu. Ya. Boguslavskii. 19(7), 878–9 (Jan. 1975); CPM-7503X0766

Boiko, V. A.—Low-voltage gun with a resonator for formation of electron bunches in a linear accelerator —V. A. Boiko, R. M. Voronkov, and V. A. Danilichev. 19(4), 569–71 (Oct. 1974); CPM-7412X0353

Bolgov, É. I.—Cell for forming electron beams of arbitrary shape in a high-voltage gaseous discharge —I. V. Vagner, É. I. Bolgov, V. F. Grakun, V. L. Gokhfel'd, and V. A. Kudlai. 19(8), 1042–5 (Feb. 1975); CPM-7504X1466

Bolotin, L. I.—Interaction of a hollow electron beam with a plasma —N. M. Zemlyanskii, A. K. Berezin, Ya. B. Fainberg, L. I. Bolotin, and S. S. Krivulya. 19(12), 1547–8 (Jun. 1975); CPM-7508X0421

Bolotov, B. B.—Energy losses of slow electrons reflected from molybdenum and tungsten single crystals —O. M. Artamonov, B. B. Bolotov, and M. V. Kremkov. 19(8), 1103–4 (Feb. 1975); CPM-7504X1527

Bonch-Bruevich, A. M.—Optical characteristics of K-8 glass subject to radiation from a neodymium laser —A. M. Bonch-Bruevich, Ya. A. Imas, V. S. Salyadinov, and A. V. Shatilov. 19(2), 287–9 (Aug. 1974); CPM-7408X1551

—Frequency-doubling single-mode laser for picosecond pulses —A. M. Bonch-Bruevich, A. M. Tkachuk, and A. A. Fedorov. 19(4), 549–51 (Oct. 1974); CPM-7412X0333

—Surface evaporation of a solid transparent dielectric under the action of laser radiation —A. M. Bonch-Bruevich, Ya. A. Imas, A. A. Kovalev, P. S. Kondratenko, and B. I. Makshantsev. 19(11), 1474–6 (May 1975); CPM-7506X1228

Bonch-Bruevich, V. A.—Strobe unit for measuring luminescence in the range 10^{-7}-$2\cdot10^{-10}$ sec —V. A. Bonch-Bruevich and N. A. Tolstoi. 19(2), 284–6 (Aug. 1974); CPM-7408X1548

Bondarenko, A. V.—Mass and energy analysis of ions in the cathode of an anomalous glow discharge. II. Binary gas mixtures Ne+Ar and N_2+Ar —A. V. Bondarenko. 19(7), 914–8 (Jan. 1975); CPM-7503X0802

Bondarenko, N. F.—Possible electrohydrodynamic effects in electrolytes —E. Z. Gak, É. Kh. Rokhinson, and N. F. Bondarenko. 19(5), 676–7 (Nov. 1974); CPM-7501X0470

Bondarenko, S. I.—Shielding properties of superconducting shields —S. I. Bondarenko, S. S. Vinogradov, G. A. Gogadze, S. S. Perepelkin, and V. I. Sheremet. 19(6), 824–8 (Dec. 1974); CPM-7501X0824

—Superconducting magnetic shields —S. I. Bondarenko and V. I. Sheremet. 19(7), 952–5 (Jan. 1975); CPM-7503X0840

Bondarenko, V. D.—Analytic model for the arc regime and the thermionic converter —V. D. Bondarenko and A. I. Loshkarev. 19 (12), 1564–8 (Jun. 1975); CPM-7508X0438

Bondarenko, V. N.—Elimination of carbon impurities from platinum by heating in an oxygen atmosphere —L. P. Rekova, V. V. Mozgin, L. N. Zvyagintseva, V. N. Bondarenko, and Ya. M. Fogel'. 19(11), 1465–7 (May 1975); CPM-7506X1219

Borisov, D. G.—Linear accelerator for beam injection into a slowly rising magnetic field —D. G. Borisov, A. I. Gryzlov, V. M. Levin, and A. V. Ryabtsov. 19(4), 509–10 (Oct. 1974); CPM-7412X0293

Borisov, S. F.—Flow of low-density gases in a capillary grid —B. T. Porodnov, V. D. Akin'shin, V. I. Kichaev, S. F. Borisov, and P. E. Suetin. 19(4), 515–8 (Oct. 1974); CPM-7412X0299

Bortniker, V. Yu.—Cumulative destruction of transparent dielectrics in repeated laser irradiation —L. D. Khazov, I. A. Fersman, and V. Yu. Bortniker. 19(9), 1256–7 (Mar. 1975); CPM-7505X0678

Bredikhin, M. Yu.—Spatial characteristics and loss of plasma produced by an electron beam in a magnetic trap —M. Yu. Bredikhin, A. I. Maslov, A. I. Skibenko, E. I. Skibenko, I. P. Fomin, and V. B. Yuferov. 19(1), 49–52 (Jul. 1974); CPM-7407X1561

Brusilovskii, B. A.—Effect of crystal structure on certain angular dependence of the ion-electron-emission yield —B. A. Brusilovskii and V. A. Molchanov. 19(1), 84–7 (Jul. 1974); CPM-7407X1596

Bryukhovetskii, A. S.—Microwave discharge in argon —E. V. Belousov, A. S. Bryukhovetskii, and A. V. Prokopov. 19(1), 53–6 (Jul. 1974); CPM-7407X1565

Bublik, V. T.—Crystal defects of heterostructures of AlAs–GaAs solid solutions and effect on the characteristics of injection lasers —L. V. Druzhinina, V. T. Bublik, L. M. Dolginov, P. G. Eliseev, M. P. Kerbelev, V. B. Osvenskii, I. Z. Pinsker, and M. G. Shumskii. 19(7), 935–9 (Jan. 1975); CPM-7503X0823

Bugaev, S. P.—Perveance of a vacuum with a point cathode —S. P. Bugaev, E. A. Litvinov, V. V. Lopatin, and G. A. Mesyats. 19(1), 88–90 (Jul. 1974); CPM-7407X1600

—Electron energy spectrum in a high-current vacuum diode —S. P. Bugaev, V. I. Koshelev, and M. N. Timofeev. 19(9), 1193–5 (Mar. 1975); CPM-7505X0615

Bulanov, S. V.—Magnetohydrodynamic stability of a neutral current layer in a plasma —S. V. Bulanov. 19(9), 1246–7 (Mar. 1975); CPM-7505X0668

Bulgakov, M. K.—Two-omegatron study of the pumping characteristics of an NÉM-300 magnetic discharge pump for a mixture of gases —M. K. Bulgakov and V. G. Rogozinskii. 19(3), 427–8 (Sep. 1974); CPM-7412X1113

Bulyginskii, D. G.—Generation of drift waves by an rf field near the lower hybrid frequency —Yu. F. Baranov, D. G. Bulyginskii, M. I. Vil'dzhyunas, B. V. Galaktionov, and N. V. Shustova. 19(6), 732–5 (Dec. 1974); CPM-7501X0732

Burtsev, V. A.—Coaxial plasma injector with programmed injection —V. A. Burtsev, V. N. Litunovskii, and M. P. Nadgornaya. 19(6), 736–40 (Dec. 1974); CPM-7501X0736

Burunov, E. A.—Diagnostics of a laser-produced plasma by a scattering method using an electron-optical image converter —E. A. Burunov, G. M. Malyshev, G. T. Razdobarin, and V. V. Semenov. 19(1), 66–9 (Jul. 1974); CPM-7407X1578

Bushuev, V. A.—Contribution of multiphoton processes to the linear dielectric constant —V. A. Bushuev and R. N. Kuz'min. 19(1), 116 (Jul. 1974); CPM-7407X1628

—Coherent Compton effect in crystals —V. A. Bushuev and R. N. Kuz'min. 19(12), 1590–2 (Jun. 1975); CPM-7508X0464

Busov, V. M.–Electroluminescence spectra of the red luminescent diodes p–$Al_xGa_{1-x}As$—n–$AlyGa_{1-y}As(y>x)$ —V. M. Busov, D. Z. Garbuzov, A. T. Gorelenok, and D. S. Kop'ev. 19(12), 1598–600 (Jun. 1975); CPM-7508X0472

Buts, V. A.—Stability of the diode —V. A. Buts. 19(8), 1034–7 (Feb. 1975); CPM-7504X1458

—Spectral narrowing of a single-mode beam oscillator —V. A. Buts and V. I. Kurilko. 19(11), 1494–5 (May 1975); CPM-7506X1248

—Stabilization of two-stream instabilities —V. A. Buts. 19(11), 1496–7 (May 1975); CPM-7506X1250

Butslov, M. M.—Electron repulsion in a time-resolving electron-optical image converter —M. M. Butslov and M. E. Gertsenshtein. 19(1), 129–30 (Jul. 1974); CPM-7407X1641

Butusov, M. M.—Optical simulation of a radiator aperture with arbitrary amplitude—phase distribution —M. M. Butusov and Sh. V. Yurevichyus. 19(6), 833–4 (Dec. 1974); CPM-7501X0833

Bychkov, Yu. I.—Ionization and recombination coefficients in a discharge excited by fast electrons —Yu. I. Bychkov, Yu. D. Korolev, and A. P. Khuzeev. 19(1), 140–1 (Jul. 1974); CPM-7407X1652

—Energy input in electrical ionization lasers —Yu. I. Bychkov, Yu. D. Korolev, Yu. A. Kurbatov, and G. A. Mesyats. 19(4), 499–502 (Oct. 1974); CPM-7412X0283

—Characteristics of the electrical ionization CO_2 laser —Yu. I. Bychkov, Yu. A. Kurbatov, and V. V. Savin. 19(4), 506–8 (Oct. 1974); CPM-7412X0290

—Infrared nitrogen laser using a transverse discharge —V. F. Tarasenko and Yu. I. Bychkov. 19(5), 693 (Nov. 1974); CPM-7501X0487

Bykovskii, Yu. A.—Recombination in an expanding plasma —Yu. A. Bykovskii, N. N. Degtyarenko, V. F. Elesin, V. E. Kondrashov, E. E. Lovetskii, A. N. Polyanichev, and V. S. Fetisov. 19(1), 43–8 (Jul. 1974); CPM-7407X1555

—Neutral particles from the interaction of laser radiation with a solid target —Yu. A. Bykovskii, N. M. Vasil'ev, I. D. Laptev, and V. N. Nevolin. 19(12), 1635 (Jun. 1975); CPM-7508X0509

Bystrov, Yu. A.—Development of an inhibited glow discharge —Yu. A. Bystrov, S. A. Ivanov, and Yu. F. Radchenko. 19(11), 1447–8 (May 1975); CPM-7506X1201

C

Chaikovski, A. P.—Measurement of statistical parameters of scattering particles in laminar flow by Doppler spectroscopy —A. P. Ivanov, A. Ya. Khairullina, and A. P. Chaikovski. 19(2), 267–70 (Aug. 1974); CPM-7408X1531

Chedzhemov, G. Kh.—Stigmatic sectored magnetic analyzer for a multiple-beam mass spectrometer —G. Kh. Chedzhemov. 19(11), 1516–7 (May 1975); CPM-7506X1270

Chekalin, É. K.—Investigation of ionization processes behind strong shock waves using an electrical conductivity probe —V. A. Tishchenko, N. V. Khandurov, and É. K. Chekalin. 19(5), 651–3 (Nov. 1974); CPM-7501X0445

Chekmarev, I. B.—Diffusion regime for electrostatic probes as singular-perturbation problem —I. B. Chekmarev. 19(10), 1287–9 (Apr. 1975); CPM-7506X0221

Chekmareva, O. M.—Stefan problem with motion of the phase-transition surface described by $y(\tau) = \sqrt{A\tau^2+B\tau+h^2}$ —O. M. Chekmareva. 19(10), 1273–6 (Apr. 1975); CPM-7506X0207

Chepegin, V. N.—Efficiency of internal targets in the accelerator at the Institute of High-Energy Physics —V. I. Gridasov, K. P. Myznikov, and V. N. Chepegin. 19(7), 922–5 (Jan. 1975); CPM-7503X0810

Cherepanov, B. S.—Dielectric properties of foamed ceramics at millimeter wavelengths —N. A. Irisova, G. V. Kozlov, V. E. Mandrusov, B. S. Cherepanov, and I. M. Chernyshev. 19(1), 103–4 (Jul. 1974); CPM-7407X1615

Chernov, A. A.—Anomalous resistivity of transverse plasma current at electron-cyclotron harmonics —V. I. Aref'ev and A. A. Chernov. 19(12), 1522–8 (Jun. 1975); CPM-7508X0396

Chernov, V. A.—Effect of electron reflection on the voltage–current characteristics of a high-voltage, hollow-cathode, glow discharge —Ya. Ya. Udris, V. A. Chernov, and L. G. Guseva. 19(1), 134–5 (Jul. 1974); CPM-7407X1646

Chernyshev, I. M.—Dielectric properties of foamed ceramics at millimeter wavelengths —N. A. Irisova, G. V. Kozlov, V. E. Mandrusov, B. S. Cherepanov, and I. M. Chernyshev. 19(1), 103–4 (Jul. 1974); CPM-7407X1615

Chertkov, A. A.—Pulsed neodymium–glass laser with periodic Q switching —T. A. Kuzovkova, E. V. Nilov, V. A. Rusov, I. N. Semenov, and A. A. Chertkov. 19(4), 503–5 (Oct. 1974); CPM-7412X0287

Chesonis, V. I.—Skin effect in a constant magnetic field —Z. K. Yankauskas, V. I. Chesonis, and V. G. Skripnik. 19(9), 1251–2 (Mar. 1975); CPM-7505X0673

Chetvertkov, V. I.—Focusing of an astigmatic beam by a doublet and a symmetric triplet of quadrupole lenses —V. I. Chetvertkov. 19 (1), 1–2 (Jul. 1974); CPM-7407X1513

Chikhachev, A. S.—Impossibility of shielding against the rf radiation of a thermonuclear reactor with a cold-plasma sheath —A. S. Chikhachev. 19(5), 685 (Nov. 1974); CPM-7501X0479

Chirkin, A. S.—Direct and cascade four-photon parametric scattering of light in $LiIO_3$ crystals —S. M. Arakelyan, V. G. Tunkin, A. I. Kholodnykh, and A. S. Chirkin. 19(6), 787–92 (Dec. 1974); CPM-7501X0787

Chistyakov, P. N.—Investigation of the work function of a tungsten cathode after bombardment by inert-gas ions —P. N. Chistyakov, R. A. Milovanova, and V. V. Lytkin. 19(1), 148–9 (Jul. 1974); CPM-7407X1660

Chuiko, V. I.—Proton extraction from the 70-GeV accelerator for the Ludmila liquid-hydrogen chamber (extraction system S) —A. A. Aseev, A. I. Drozhdin, B. A. Zelenov, É. A. Merker, L. L. Moizhes, K. P. Myznikov, A. A. Roshchin, V. M. Tatarenko, M. A. Kholodenko, A. D. Artemov, L. N. Vaulin, V. I. Gordin, I. I. Kovalevskii, V. N. Rozhkov, M. M. Suvorov, A. S. Sudarushkin, and V. I. Chuiko. 19(1), 70–6 (Jul. 1974); CPM-7407X1582

Churin, A. A.—Thermal effect of continuous laser radiation on optically transparent media —N. S. Bardina, A. I. Portnyagin, M. Yu. Sklyarov, and A. A. Churin. 19(4), 491–4 (Oct. 1974); CPM-7412X0275

Chutov, Yu. I.—Physical properties of an electrodeless pulsed discharge in a gas-filled glass cell —Yu. I. Chutov, N. S. Baranchuk, M. R. Lozovich, and V. G. Danilov. 19(2), 224–8 (Aug. 1974); CPM-7408X1488

D

Danilichev, V. A.—Low-voltage gun with a resonator for formation of electron bunches in a linear accelerator —V. A. Boiko, R. M. Voronkov, and V. A. Danilichev. 19(4), 569–71 (Oct. 1974); CPM-7412X0353

Danilov, V. G.—Physical properties of an electrodeless pulsed discharge in a gas-filled glass cell —Yu. I. Chutov, N. S. Baranchuk, M. R. Lozovich, and V. G. Danilov. 19(2), 224–8 (Aug. 1974); CPM-7408X1488

Danilov, V. N.—Optimization of the paraxial asymptotic electric field in electron-optical systems —V. E. Ginzburg and V. N. Danilov. 19(3), 407–9 (Sep. 1974); CPM-7412X1093

Davydov, V. B.—Effects of ion microfields on emission of an arc cathode —A. M. Dorodnov, V. B. Davydov, A. V. Kozyrev, and Ya. A. Pomelov. 19(3), 390–3 (Sep. 1974); CPM-7412X1076

Davydova, T. A.—Emission of waves from a plasma layer —T. A. Davydova and A. A. Zhmudskii. 19(1), 12–5 (Jul. 1974); CPM-7407X1524

Davydovskii, V. Ya.—Radiation emitted by charged particles trapped by plane electromagnetic waves —V. Ya. Davydovskii and A. S. Ukolov. 19(8), 1057–60 (Feb. 1975); CPM-7504X1481

—Energy of charged particles accelerated by electromagnetic waves in a plasma with a spatially decreasing density —V. Ya. Davydovskii and A. S. Ukolov. 19(10), 1303–7 (Apr. 1975); CPM-7506X0237

Dedik, A. N.—Self-acceleration of an intense electron beam —I. A. Grishaev, A. N. Dedik, V. V. Zakutin, I. I. Magda, Yu. V. Tkach, and A. M. Shenderovich. 19(8), 1087–9 (Feb. 1975); CPM-7504X1511

Degtyarenko, N. N.—Recombination in an expanding plasma —Yu. A. Bykovskii, N. N. Degtyarenko, V. F. Elesin, V. E. Kondrashov, E. E. Lovetskii, A. N. Polyanichev, and V. S. Fetisov. 19(1), 43–8 (Jul. 1974); CPM-7407X1555

Demchenko, P. A.—High-frequency modulation of atomic beams for plasma diagnostics —P. A. Demchenko, L. I. Krupnik, K. A. Leontovich, and E. S. Lyangner. 19(10), 1362–6 (Apr. 1975); CPM-7506X0296

—Free expansion of plasma jets —P. A. Demchenko, L. I. Krupnik, and E. S. Lyangner. 19(11), 1426–8 (May 1975); CPM-7506X1180

Dement'ev, A. S.—Microwave maser with nonrelativistic electrons —A. S. Dement'ev and Yu. G. Pavlenko. 19(5), 694–5 (Nov. 1974); CPM-7501X0488

Demidenko, I. I.—Focusing of a neutralized ion beam by a plasma-optics system —I. I. Demidenko, N. S. Lomino, A. I. Morozov, and V. G. Padalka. 19(3), 347–50 (Sep. 1974); CPM-7412X1033

—Effect of rf ionization on Hall-current plasma accelerator —I. I. Demidenko, N. S. Lomino, A. I. Morozov, and V. G. Padalka. 19 (12), 1560–3 (Jun. 1975); CPM-7508X0434

Demin, V. N.—Double focusing in a system of $1/r$ electric and magnetic fields —V. V. Zashkvara and V. N. Demin. 19(9), 1219–20 (Mar. 1975); CPM-7505X0641

Demirkhanov, R. A.—Low pressure discharge with high-energy electrons —R. A. Demirkhanov, Yu. V. Kursanov, and L. P. Skripal'. 19(7), 891–4 (Jan. 1975); CPM-7503X0779

Denisyuk, Yu. N.—Imaging properties of traveling intensity waves in the recording of dynamic three-dimensional holograms —Yu. N. Denisyuk. 19(1), 77–80 (Jul. 1974); CPM-7407X1589

Deryagin, V. N.—Time characteristics of the near radiation field of the injection laser —Zh. I. Alferov, V. N. Deryagin, L. E. Marasin, Yu. V. Popov, and E. L. Portnoi. 19(4), 548 (Oct. 1974); CPM-7412X0332

Diasamidze, Zh. M.—Effect of a high-frequency electric field on the energy loss of a charged particle in a medium —Zh. M. Diasamidze. 19(5), 687–8 (Nov. 1974); CPM-7501X0481

Didenko, A. N.—Reflection of a high-current relativistic electron beam from a conducting surface —A. N. Didenko, A. I. Ryabchikov, V. A. Tuzov, and Yu. P. Usov. 19(12), 1625–6 (Jun. 1975); CPM-7508X0499

Dimov, G. I.—Formation of a narrow gas jet in vacuum —G. I. Dimov and V. Ya. Savkin. 19(6), 755–8 (Dec. 1974); CPM-7501X0755

Dmitrenko, B. I.—Effect of a high-current relativistic electron beam on a metal —B. I. Dmitrenko, L. V. Leskov, G. P. Maksimov, S. L. Nedoseev, V. V. Savichev, V. P. Smirnov, and A. M. Spektor. 19(9), 1224–5 (Mar. 1975); CPM-7505X0646

Dneprovskii, V. G.—Condensation of a dense vapor flow —V. G. Dneprovskii, B. A. Osadin, and N. V. Rusakov. 19(2), 271–4 (Aug. 1974); CPM-7408X1535

—Effect of focusing conditions on the morphology of surface films produced with a laser —V. G. Dneprovskii and B. A. Osadin. 19 (2), 275–7 (Aug. 1974); CPM-7408X1539

Dnestrovskii, Yu. N.—Energy balance in Tokamaks in the "plateau—banana" transition region —Yu. N. Dnestrovskii and D. P. Kostomarov. 19(12), 1541–2 (Jun. 1975); CPM-7508X0415

Dolginov, L. M.—Crystal defects of heterostructures of AlAs–GaAs solid solutions and effect on the characteristics of injection lasers —L. V. Druzhinina, V. T. Bublik, L. M. Dolginov, P. G. Eliseev, M. P. Kerbelev, V. B. Osvenskii, I. Z. Pinsker, and M. G. Shumskii. 19(7), 935–9 (Jan. 1975); CPM-7503X0823

Dolzhenko, O. V.—Excitation of surface electromagnetic waves in a plasma cylinder surrounded by a hollow electron beam —O. V. Dolzhenko, A. V. Zosimov, and A. A. Rukhadze. 19(5), 618–21 (Nov. 1974); CPM-7501X0412

Donov, V. A.—Thermal diffusion in a mixture of cesium vapor and helium —E. S. Bekmukhambetov and V. A. Donov. 19(12), 1627–8 (Jun. 1975); CPM-7508X0501

Dorodnov, A. M.—Effects of ion microfields on emission of an arc cathode —A. M. Dorodnov, V. B. Davydov, A. V. Kozyrev, and Ya. A. Pomelov. 19(3), 390–3 (Sep. 1974); CPM-7412X1076

Doroshenko, A. P.—Two-section solenoid with internal "equally-loaded" section; power as a function of the length of the internal section —G. S. Veisig, A. P. Doroshenko, and P. P. Rybin. 19(3), 416–8 (Sep. 1974); CPM-7412X1102

Dougar-Jabon, V. D.—Radio-frequency absorption in a plasma confined by rf plugs —K. S. Golovanivskii, V. D. Dougar-Jabon, and L. A. Pokhmel'nykh. 19(11), 1484–5 (May 1975); CPM-7506X1238

Dovator, N. A.—Measurement of transverse relaxation time T_2 of optically oriented He^4 with an oscillator magnetometer —N. A. Dovator, R. A. Zhitnikov, and P. P. Kuleshov. 19(12), 1608–9 (Jun. 1975); CPM-7508X0482

Dovgopol, S. P.—Linear transient response of a fully ionized plasma in a pulsed electric field —V. V. Istomin, S. P. Sher, and S. P. Dovgopol. 19(7), 963–4 (Jan. 1975); CPM-7503X0851

Dovzhenko, V. A.—Effect of ion current on the measurement of the electron energy distribution function by the second-derivative method —V. A. Dovzhenko, A. P. Ershov, and G. S. Solntsev. 19 (4), 538–9 (Oct. 1974); CPM-7412X0322

Drozhdin, A. I.—Proton extraction from the 70-GeV accelerator for the Ludmila liquid-hydrogen chamber (extraction system S) —A. A. Aseev, A. I. Drozhdin, B. A. Zelenov, É. A. Merker, L. L. Moizhes, K. P. Myznikov, A. A. Roshchin, V. M. Tatarenko, M. A. Kholodenko, A. D. Artemov, L. N. Vaulin, V. I. Gordin, I. I. Kovalevskii, V. N. Rozhkov, M. M. Suvorov, A. S. Sudarushkin, and V. I. Chuiko. 19(1), 70–6 (Jul. 1974); CPM-7407X1582

Druzhinina, L. V.—Crystal defects of heterostructures of AlAs–GaAs solid solutions and effect on the characteristics of injection lasers —L. V. Druzhinina, V. T. Bublik, L. M. Dolginov, P. G. Eliseev, M. P. Kerbelev, V. B. Osvenskii, I. Z. Pinsker, and M. G. Shumskii. 19(7), 935–9 (Jan. 1975); CPM-7503X0823

Dryakhlushin, V. F.—Surface waves in periodic plasma systems —V. F. Dryakhlushin and Yu. A. Romanov. 19(7), 883–6 (Jan. 1975); CPM-7503X0771

Dubinskii, V. E.—Extrapolation of the Langmuir S-curve to cesium pressures of 10–100 torr —V. E. Dubinskii and S. Ya. Lebedev. 19 (1), 81–3 (Jul. 1974); CPM-7407X1593

Dubovoi, L. V.—Interaction of intense laser radiation with solid targets —L. V. Dubovoi, V. D. Dyatlov, V. I. Kryzhanovskii, A. A. Mak, R. N. Medvedev, A. N. Popytaev, V. A. Serebryakov, V. N. Sizov, and A. D. Starikov. 19(11), 1477–9 (May 1975); CPM-7506X1231

Dushin, L. A.—Modulation of microwaves by density fluctuations in a plasma —L. A. Dushin, A. V. Serikov, A. I. Skibenko, E. V. Krivorukov, and I. P. Fomin. 19(9), 1163–7 (Mar. 1975); CPM-7505X0585

D'yachenko, V. V.—Role of collisions in plasma absorption of electromagnetic waves near the lower hybrid —B. V. Galaktionov, V. V. D'yachenko, M. M. Larionov, and O. N. Shcherbinin. 19(4), 459–62 (Oct. 1974); CPM-7412X0243

Dyatlov, V. D.—Interaction of intense laser radiation with solid targets —L. V. Dubovoi, V. D. Dyatlov, V. I. Kryzhanovskii, A. A. Mak, R. N. Medvedev, A. N. Popytaev, V. A. Serebryakov, V. N. Sizov, and A. D. Starikov. 19(11), 1477–9 (May 1975); CPM-7506X1231

Dyatlov, V. G.—Magnetic field in a θ pinch with an axial conductor —Ya. F. Volkov, V. G. Dyatlov, and N. I. Mitina. 19(3), 323–5 (Sep. 1974); CPM-7412X1009

—Optical investigation of a turbulent plasma —Ya. F. Volkov, V. G. Dyatlov, and N. I. Mitina. 19(7), 905–8 (Jan. 1975); CPM-7503X0793

Dzhavakhishvili, D. I.—Longitudinal oscillations in an ultrarelativistic electron plasma —D. I. Dzhavakhishvili. 19(1), 115 (Jul. 1974); CPM-7407X1627

—Ion-acoustic instability of a fully ionized ultrarelativistic plasma in an electric field —D. I. Dzhavakhishvili. 19(7), 959–60 (Jan. 1975); CPM-7503X0847

E

Éfendiev, A. Z.—Behavior of molten salts in strong electric fields —A. Z. Éfendiev, O. M. Shabanov, S. M. Gadzhiev, and S. M. Tagirov. 19(6), 820–3 (Dec. 1974); CPM-7501X0820

Egorenkov, V. D.—High-frequency instabilities in an inhomogeneous, anisotropic finite-β plasma —V. D. Egorenkov and A. I. Pyatak. 19(9), 1160–2 (Mar. 1975); CPM-7505X0582

Egorov, N. P.—Mass-spectrometer study of the ion composition of a glow discharge —N. P. Egorov and V. N. Komarov. 19(8), 1100–2 (Feb. 1975); CPM-7504X1524

Egorov, N. V.—Preservation of semiconductor field-emission cathodes —N. V. Egorov, G. N. Fursei, and M. K. El'Nimr. 19(5), 709 (Nov. 1974); CPM-7501X0503

Elesin, V. F.—Recombination in an expanding plasma —Yu. A. Bykovskii, N. N. Degtyarenko, V. F. Elesin, V. E. Kondrashov, E. E. Lovetskii, A. N. Polyanichev, and V. S. Fetisov. 19(1), 43–8 (Jul. 1974); CPM-7407X1555

Elfimov, A. G.—Excitation of Alfvén waves in decay instabilities —A. G. Elfimov and F. M. Nekrasov. 19(1), 9–11 (Jul. 1974); CPM-7407X1521

Eliseev, P. G.—Crystal defects of heterostructures of AlAs–GaAs solid solutions and effect on the characteristics of injection lasers —L. V. Druzhinina, V. T. Bublik, L. M. Dolginov, P. G. Eliseev, M. P. Kerbelev, V. B. Osvenskii, I. Z. Pinsker, and M. G. Shumskii. 19(7), 935–9 (Jan. 1975); CPM-7503X0823

El'Nimr, M. K.—Preservation of semiconductor field-emission cathodes —N. V. Egorov, G. N. Fursei, and M. K. El'Nimr. 19(5), 709 (Nov. 1974); CPM-7501X0503

Emets, Yu. P.—Conductivity of a medium with inhomogeneous inclusions in a magnetic field —Yu. P. Emets. 19(5), 586–8 (Nov. 1974); CPM-7501X0380

Énder, A. Ya.—Effect of electron-atom collisions on electron motion in a gas diode —V. I. Babanin and A. Ya. Énder. 19(1), 60–5 (Jul. 1974); CPM-7407X1572

Épshtein, É. M.—Resonant amplification of an image potential by an electromagnetic wave —Yu. I. Balkarei and É. M. Épshtein. 19(6), 843–4 (Dec. 1974); CPM-7501X0843

Eremeev, M. A.—Thermionic emission properties of zirconium, hafnium, and titanium nitrides in cesium vapor —M. A. Eremeev, V. S. Neshpor, A. B. Novikov, E. M. Stefanovskaya, and V. P. Fedorinov. 19(10), 1337–41 (Apr. 1975); CPM-7506X0271

Ermakov, G. A.—Calculation of permittivity of an inhomogeneous dielectric by a variational method —G. A. Ermakov, A. G. Fokin, and T. D. Shermergor. 19(2), 157–60 (Aug. 1974); CPM-7408X1421

—Calculation of bounds for the effective permittivity of an inhomogeneous dielectric —G. A. Ermakov, A. G. Fokin, and T. D. Shermergor. 19(2), 161–5 (Aug. 1974); CPM-7408X1425

Ermolin, V. V.—Effect of plasma parameters on emission in an ion laser —I. E. Sakharov, V. V. Ermolin, and S. V. Shatalin. 19(8), 1081–4 (Feb. 1975); CPM-7504X1505

Ershov, A. P.—Effect of ion current on the measurement of the electron energy distribution function by the second-derivative method —V. A. Dovzhenko, A. P. Ershov, and G. S. Solntsev. 19 (4), 538–9 (Oct. 1974); CPM-7412X0322

Evdokimov, O. B.—Ionization of a gas-discharge gap by fast electrons —O. B. Evdokimov and A. P. Yalovets. 19(1), 138–9 (Jul. 1974); CPM-7407X1650

Evteev, V. N.—Axially symmetric neutralized electron beam —G. N. Vyalov, V. N. Evteev, Yu. M. Zolotaikin, and K. N. Ul'yanov. 19 (11), 1414–7 (May 1975); CPM-7506X1168

F

Fainberg, Ya. B.—Launching and propagation of regular nonlinear waves in an anisotropic plasma-filled waveguide —V. I. Kurilko, A. P. Tols-toluzhskii, and Ya. B. Fainberg. 19(5), 622–7 (Nov. 1974); CPM-7501X0416

—Interaction of a hollow electron beam with a plasma —N. M. Zemlyanskii, A. K. Berezin, Ya. B. Fainberg, L. I. Bolotin, and S. S. Krivulya. 19(12), 1547–8 (Jun. 1975); CPM-7508X0421

Fainshtein, S. M.—Nonlinear plasma waves and ion-acoustic waves in an isotropic plasma —V. Sh. Livadonov and S. M. Fainshtein. 19(1), 28–30 (Jul. 1974); CPM-7407X1540

Farenik, V. I.—Plasma decay instability in crossed fields —V. I. Farenik, V. V. Vlasov, A. M. Rozhkov, and A. A. Kozharin. 19(8), 1116–7 (Feb. 1975); CPM-7504X1540

—Ion energy spectra and collective effects in a Penning ion source —V. I. Farenik, V. V. Vlasov, A. M. Rozhkov, and A. A. Kozharin. 19(9), 1258–9 (Mar. 1975); CPM-7505X0680

Fedichev, S. V.—Titanium adsorption on tungsten —Yu. K. Ustinov and S. V. Fedichev. 19(8), 1118–9 (Feb. 1975); CPM-7504X1542

Fedorenko, V. N.—Generation of Bernstein modes in beam-plasma system —V. N. Fedorenko. 19(2), 171–4 (Aug. 1974); CPM-7408X1435

Fedorinov, V. P.—Thermionic emission properties of zirconium, hafnium, and titanium nitrides in cesium vapor —M. A. Eremeev, V. S. Neshpor, A. B. Novikov, E. M. Stefanovskaya, and V. P. Fedorinov. 19(10), 1337–41 (Apr. 1975); CPM-7506X0271

Fedorov, A. A.—Frequency-doubling single-mode laser for picosecond pulses —A. M. Bonch-Bruevich, A. M. Tkachuk, and A. A. Fedorov. 19(4), 549–51 (Oct. 1974); CPM-7412X0333

Fedorov, V. I.—Absolute decay instability of low-frequency waves in an inhomogeneous plasma —A. D. Piliya and V. I. Fedorov. 19(5), 686 (Nov. 1974); CPM-7501X0480

Fedyakova, V. P.—Stabilization of MHD instabilities by a high-frequency current in a straight system —V. P. Fedyakova. 19(1), 16–9 (Jul. 1974); CPM-7407X1528

Ferleger, V. Kh.—Doppler profile of an atomic line to the differential excitation cross section —É. S. Parilis and V. Kh. Ferleger. 19(10), 1367–70 (Apr. 1975); CPM-7506X0301

Fersman, I. A.—Cumulative destruction of transparent dielectrics in repeated laser irradiation —L. D. Khazov, I. A. Fersman, and V. Yu. Bortniker. 19(9), 1256–7 (Mar. 1975); CPM-7505X0678

Fetisov, V. S.—Recombination in an expanding plasma —Yu. A. Bykovskii, N. N. Degtyarenko, V. F. Elesin, V. E. Kondrashov, E. E. Lovetskii, A. N. Polyanichev, and V. S. Fetisov. 19(1), 43–8 (Jul. 1974); CPM-7407X1555

—Expansion of a recombining plasma in vacuum —E. E. Lovetskii, A. N. Polyanichev, and V. S. Fetisov. 19(5), 647–50 (Nov. 1974); CPM-7501X0441

Fidel'skaya, R. P.—Beam focusing in an accelerator with inductive energy storage —V. A. Glukhikh, O. A. Gusev, E. G. Komar, V. S. Kuznetsov, M. P. Svin'in, and R. P. Fidel'skaya. 19(3), 366–7 (Sep. 1974); CPM-7412X1052

—Estimate of the angular divergence in intense electron beams —V. S. Kuznetsov, Yu. P. Vakhrushin, O. L. Komarov, and R. P. Fidel'skaya. 19(7), 868–70 (Jan. 1975); CPM-7503X0756

Fikhmanas, R. F.—Upper and lower limits on the capacitance of a plane capacitor —R. F. Fikhmanas and P. Sh. Fridberg. 19(5), 683–4 (Nov. 1974); CPM-7501X0477

Filippov, Yu. F.—Reflection of finite amplitude electromagnetic waves from a semiconductor plasma —Yu. F. Filippov. 19(5), 603–6 (Nov. 1974); CPM-7501X0397

Fisher, V. I.—Effect of loss on electron avalanches in optical breakdown —V. I. Fisher. 19(8), 1050–2 (Feb. 1975); CPM-7504X1474

Fishkova, T. Ya.—Fifth-order spherical aberration in focusing and correcting quadrupole—octupole systems —Ya. G. Lyubchik and T. Ya. Fishkova. 19(11), 1403–7 (May 1975); CPM-7506X1157

—Electron-optical properties of postdeflection quadrupole lenses —T. Ya. Fishkova. 19(12), 1618–9 (Jun. 1975); CPM-7508X0492

Fogel', Ya. M.—Elimination of carbon impurities from platinum by heating in an oxygen atmosphere —L. P. Rekova, V. V. Mozgin, L. N. Zvyagintseva, V. N. Bondarenko, and Ya. M. Fogel'. 19(11), 1465–7 (May 1975); CPM-7506X1219

—Mass spectrum of secondary ions ejected from the surface of a single crystal of gallium arsenide by argon ions —A. G. Koval', V. V. Bobkov, Yu. A. Klimovskii, S. S. Strel'chenko, V. V. Shubina, V. V. Lebedev, and Ya. M. Fogel'. 19(12), 1587–9 (Jun. 1975); CPM-7508X0461

Fokin, A. G.—Calculation of permittivity of an inhomogeneous dielectric by a variational method —G. A. Ermakov, A. G. Fokin, and T. D. Shermergor. 19(2), 157–60 (Aug. 1974); CPM-7408X1421

—Calculation of bounds for the effective permittivity of an inhomogeneous dielectric —G. A. Ermakov, A. G. Fokin, and T. D. Shermergor. 19(2), 161–5 (Aug. 1974); CPM-7408X1425

Fomin, I. P.—Spatial characteristics and loss of plasma produced by an electron beam in a magnetic trap —M. Yu. Bredikhin, A. I. Maslov, A. I. Skibenko, E. I. Skibenko, I. P. Fomin, and V. B. Yuferov. 19(1), 49–52 (Jul. 1974); CPM-7407X1561

—Plasma equilibrium and confinement in a poloidal heliotron configuration. II —V. G. Zykov, V. I. Karpukhin, Yu. F. Lonin, N. N. Podteregera, N. I. Rudnev, A. Y. Skibenko, V. T. Tolok, and I. P. Fomin. 19(8), 1069–72 (Feb. 1975); CPM-7504X1493

—Modulation of microwaves by density fluctuations in a plasma —L. A. Dushin, A. V. Serikov, A. I. Skibenko, E. V. Krivorukov, and I. P. Fomin. 19(9), 1163–7 (Mar. 1975); CPM-7505X0585

Freiberg, G. N.—Emission parameters of a field-emission cathode —G. N. Freiberg. 19(10), 1352–4 (Apr. 1975); CPM-7506X0286

Fridberg, P. Sh.—Upper and lower limits on the capacitance of a plane capacitor —R. F. Fikhmanas and P. Sh. Fridberg. 19(5), 683–4 (Nov. 1974); CPM-7501X0477

Fridman, A. A.—Steady-state electron density in photoionizion of aerosol particles —G. V. Karachevtsev and A. A. Fridman. 19(11), 1471–3 (May 1975); CPM-7506X1225

Fridrikhov, S. A.—End current in a magnetron with a secondary-emission cathode —G. G. Sominskii, S. A. Fridrikhov, O. Yu. Tsybin, and A. P. Karizhskii. 19(3), 378–81 (Sep. 1974); CPM-7412X1064

Frolov, V. V.—Radiation yield of ions in liquid dielectrics as a function of temperature and radiation energy —V. I. Ivanov, E. D. Kleshchenko, Yu. P. Sukhanovskii, and V. V. Frolov. 19(11), 1468–70 (May 1975); CPM-7506X1222

Fromzel', V. A.—Unidirectional cw oscillation in a solid state ring laser with a return mirror —A. A. Mak, V. I. Ustyugov, V. A. Fromzel', and M. M. Khaleev. 19(4), 552–3 (Oct. 1974); CPM-7412X0336

—Lasing properties of Yb^{3+} and Er^{3+} glass laser pumped by a laser —V. N. Kalinin, A. A. Mak, D. S. Prilezhaev, and V. A. Fromzel'. 19(6), 835–6 (Dec. 1974); CPM-7501X0835

Fursei, G. N.—Preservation of semiconductor field-emission cathodes —N. V. Egorov, G. N. Fursei, and M. K. El'Nimr. 19(5), 709 (Nov. 1974); CPM-7501X0503

—Emission characteristics of an explosive gallium cathode —G. N. Fursei and V. M. Zhukov. 19(6), 804–7 (Dec. 1974); CPM-7501X0804

G

Gabovich, M. D.—Gas focusing of a negative-ion beam —M. D. Gabovich, A. P. Naida, I. M. Protsenko, L. S. Simonenko, and I. A. Soloshenko. 19(4), 546–7 (Oct. 1974); CPM-7412X0330

—Ion focusing of an electron beam in deep melting of a metal —M. D. Gabovich, V. P. Kovalenko, O. A. Metallov, O. K. Nazarenko, and S. K. Pats'ora. 19(7), 973–4 (Jan. 1975); CPM-7503X0861

—Measurement of ion density by the dispersion relation for an ion-beam plasma —M. D. Gabovich, L. P. Katsubo, and I. A. Soloshenko. 19(11), 1412–3 (May 1975); CPM-7506X1166

—Plasma synthesis by injection of an electron beam through an ion source —V. F. Virko, M. D. Gabovich, G. S. Kirichenko, and O. K. Nazarenko. 19(11), 1418–20 (May 1975); CPM-7506X1172

—Loss of neutralization for a stable neutralized ion beam —M. D. Gabovich. 19(11), 1502–3 (May 1975); CPM-7506X1256

Gadzhiev, S. M.—Behavior of molten salts in strong electric fields —A. Z. Éfendiev, O. M. Shabanov, S. M. Gadzhiev, and S. M. Tagirov. 19(6), 820–3 (Dec. 1974); CPM-7501X0820

Gak, E. Z.—Possible electrohydrodynamic effects in electrolytes —E. Z. Gak, É. Kh. Rokhinson, and N. F. Bondarenko. 19(5), 676–7 (Nov. 1974); CPM-7501X0470

Gal', V. V.—Electrical conductivity of a pseudoliquefied layer in an electric field —V. V. Gal', V. I. Konov, and K. A. Nikitin. 19(9), 1214–5 (Mar. 1975); CPM-7505X0636

Galaktionov, B. V.—Role of collisions in plasma absorption of electromagnetic waves near the lower hybrid —B. V. Galaktionov, V. V. D'yachenko, M. M. Larionov, and O. N. Shcherbinin. 19(4), 459–62 (Oct. 1974); CPM-7412X0243

—Generation of drift waves by an rf field near the lower hybrid frequency —Yu. F. Baranov, D. G. Bulyginskii, M. I. Vil'dzhyunas, B. V. Galaktionov, and N. V. Shustova. 19(6), 732–5 (Dec. 1974); CPM-7501X0732

Galaktionova, N. M.—Parasitic amplitude modulation of a stabilized Nd^{3+}:YAG laser —N. M. Galaktionova, A. A. Mak, and A. P. Khyuppenen. 19(4), 486–90 (Oct. 1974); CPM-7412X0270

—Solid-state laser with externally forced *Q* switching —N. M. Galaktionova, A. A. Mak, and A. P. Khyuppenen. 19(9), 1174–6 (Mar. 1975); CPM-7505X0596

Gall', L. N.—Monte Carlo analysis of ion scattering in a mass spectrometer —M. L. Aleksandrov, L. N. Gall', and N. S. Pliss. 19(6), 817–9 (Dec. 1974); CPM-7501X0817

Garbuzov, D. Z.–Electroluminescence spectra of the red luminescent diodes p–$Al_xGa_{1-x}As$—n–$AlyGa_{1-y}As(y>x)$ —V. M. Busov, D. Z. Garbuzov, A. T. Gorelenok, and D. S. Kop'ev. 19(12), 1598–600 (Jun. 1975); CPM-7508X0472

Gavrilov, N. M.—Self-excited waveguide buncher —N. M. Gavrilov and A. V. Nesterovich. 19(8), 1085–6 (Feb. 1975); CPM-7504X1509

Gel'man, Yu. A.—Composition of adsorbing and desorbing fluxes —Yu. A. Gel'man, V. I. Mikhailov, V. F. Vinogradov, and Yu. N. Lyubitov. 19(10), 1355–8 (Apr. 1975); CPM-7506X0289

Georgievskii, A. V.—Magnetic topography of toroidal systems —M. N. Skoblik, V. E. Ziser, A. V. Georgievskii, and V. G. Peletminskaya. 19(10), 1277–80 (Apr. 1975); CPM-7506X0211

Gerasimov, E. I.—Aberrations in a straight ion–optical accelerator —E. I. Gerasimov, A. I. Solnyshkov, and G. V. Tarvid. 19(1), 131–3 (Jul. 1974); CPM-7407X1643

Gerasimov, L. S.—Explosion driven magnetic generator with a matched inductive load —L. S. Gerasimov. 19(9), 1226–30 (Mar. 1975); CPM-7505X0648

Gertsenshtein, M. E.—Electron repulsion in a time–resolving electron–optical image converter —M. M. Butslov and M. E. Gertsenshtein. 19(1), 129–30 (Jul. 1974); CPM-7407X1641

Ginzburg, V. E.—Optimization of the paraxial asymptotic electric field in electron–optical systems —V. E. Ginzburg and V. N. Danilov. 19(3), 407–9 (Sep. 1974); CPM-7412X1093

Gladush, G. G.—Model for the low–voltage arc. I. Stationary solution —Yu. Yu. Abramov and G. G. Gladush. 19(6), 745–7 (Dec. 1974); CPM-7501X0745

—Model for the low–voltage arc. II. Stability —Yu. Yu. Abramov and G. G. Gladush. 19(6), 748–50 (Dec. 1974); CPM-7501X0748

Glagolev, V. M.—Anisotropic plasma heating near the lower hybrid frequency —V. M. Glagolev, V. V. Martynenko, and Yu. V. Skosyrev. 19(12), 1543–6 (Jun. 1975); CPM-7508X0417

Glasko, V. B.—Production of an ion beam by a magnetic system with opposed fields —V. B. Glasko, A. G. Sveshnikov, and N. N. Semashko. 19(2), 201–5 (Aug. 1974); CPM-7408X1465

Glatman, R. A.—Propagation of shock waves in inhomogeneous media —R. A. Glatman. 19(11), 1390–2 (May 1975); CPM-7506X1144

—Theory of nonequilibrium shock waves —R. A. Glatman and I. V. Ioffe. 19(11), 1482–3 (May 1975); CPM-7506X1236

Glebovskii, V. G.—Impurities and crystal dimensions in zone refining —V. G. Glebovskii and B. M. Shipilevskii. 19(9), 1231–5 (Mar. 1975); CPM-7505X0653

Glikman, L. G.—Charged–particle motion in a dipole magnetic field —L. G. Glikman. 19(4), 435–40 (Oct. 1974); CPM-7412X0219

—Symmetric multielectrode tubular electrostatic lenses —L. G. Glikman, V. M. Kel'man, and M. Sh. Nurmanov. 19(5), 680–2 (Nov. 1974); CPM-7501X0474

Glukhikh, V. A.—Beam focusing in an accelerator with inductive energy storage —V. A. Glukhikh, O. A. Gusev, E. G. Komar, V. S. Kuznetsov, M. P. Svin'in, and R. P. Fidel'skaya. 19(3), 366–7 (Sep. 1974); CPM-7412X1052

—High–current pulsed electron accelerator with an annular beam —M. I. Avramenko, V. A. Glukhikh, O. A. Gusev, E. G. Komar, O. L. Komarov, V. S. Kuznetsov, A. S. Perlin, and M. P. Svin'in. 19 (3), 368–70 (Sep. 1974); CPM-7412X1054

—Inductive energy storage in pulsed accelerators —V. A. Glukhikh, O. A. Gusev, E. G. Komar, and M. P. Svin'in. 19(5), 660–1 (Nov. 1974); CPM-7501X0454

Gogadze, G. A.—Shielding properties of superconducting shields —S. I. Bondarenko, S. S. Vinogradov, G. A. Gogadze, S. S. Perepelkin, and V. I. Sheremet. 19(6), 824–8 (Dec. 1974); CPM-7501X0824

Gokhfel'd, V. L.—Cell for forming electron beams of arbitrary shape in a high-voltage gaseous discharge —I. V. Vagner, É. I. Bolgov, V. F. Grakun, V. L. Gokhfel'd, and V. A. Kudlai. 19(8), 1042–5 (Feb. 1975); CPM-7504X1466

Golobovskii, Yu. B.—Theory of the positive column in neon —Yu. B. Golobovskii, Yu. M. Kagan, and R. I. Lyagushchenko. 19(3), 335–9 (Sep. 1974); CPM-7412X1021

Golovanivskii, K. S.—Radio-frequency absorption in a plasma confined by rf plugs —K. S. Golovanivskii, V. D. Dougar-Jabon, and L. A. Pokhmel'nykh. 19(11), 1484–5 (May 1975); CPM-7506X1238

Golovanov, Yu. P.—Scattering of an electron beam in a straight *dc* turbulent plasma —Yu. P. Golovanov, L. P. Zakatov, A. S. Kingsep, and A. G. Plakhov. 19(8), 1046–9 (Feb. 1975); CPM-7504X1470

Golovin, V. N.—Control of output energy in linear electron accelerators —V. N. Golovin and N. P. Sobenin. 19(7), 932–4 (Jan. 1975); CPM-7503X0820

Golubentsev, A. F.—Shot noise in a thermionic cathode —A. F. Golubentsev and A. S. Shapovalov. 19(10), 1345–6 (Apr. 1975); CPM-7506X0279

Gorban', A. N.—Atomic recombination on a solid surface —V. P. Pinchuk, A. N. Gorban', and V. G. Kornich. 19(6), 808–10 (Dec. 1974); CPM-7501X0808

Gordiets, B. F.—Gas cooling in transmission of high–power CO_2 laser radiation through the atmosphere —B. F. Gordiets, A. I. Osipov, and R. V. Khokhlov. 19(5), 669–72 (Nov. 1974); CPM-7501X0463

Gordin, V. I.—Proton extraction from the 70–GeV accelerator for the Ludmila liquid–hydrogen chamber (extraction system S) —A. A. Aseev, A. I. Drozhdin, B. A. Zelenov, É. A. Merker, L. L. Moizhes, K. P. Myznikov, A. A. Roshchin, V. M. Tatarenko, M. A. Kholodenko, A. D. Artemov, L. N. Vaulin, V. I. Gordin, I. I. Kovalevskii, V. N. Rozhkov, M. M. Suvorov, A. S. Sudarushkin, and V. I. Chuiko. 19(1), 70–6 (Jul. 1974); CPM-7407X1582

Gorelenok, A. T.—Electroluminescence spectra of the red luminescent diodes p–$Al_xGa_{1-x}As$—n–$AlyGa_{1-y}As(y>x)$ —V. M. Busov, D. Z. Garbuzov, A. T. Gorelenok, and D. S. Kop'ev. 19 (12), 1598–600 (Jun. 1975); CPM-7508X0472

Gorelik, M. S.—Propagation and stability of large amplitude ionization waves —M. S. Gorelik and L. D. Tsendin. 19(7), 880–2 (Jan. 1975); CPM-7503X0768

Gorokhov, Yu. A.—Nonlinear spherical aberrations and thermoelastic stresses in thermal self–focusing —A. A. Vigasin, Yu. A. Gorokhov, A. P. Sukhorukov, and A. M. Khachatryan. 19(5), 673–5 (Nov. 1974); CPM-7501X0467

Goryachev, D. N.—Characteristics of diffraction gratings obtained by photoetching of semiconductor surfaces —L. V. Belyakov, D. N. Goryachev, M. N. Mizerov, and E. L. Portnoi. 19(6), 837–8 (Dec. 1974); CPM-7501X0837

Grakun, V. F.—Cell for forming electron beams of arbitrary shape in a high-voltage gaseous discharge —I. V. Vagner, É. I. Bolgov, V. F. Grakun, V. L. Gokhfel'd, and V. A. Kudlai. 19(8), 1042–5 (Feb. 1975); CPM-7504X1466

Grechikhin, L. I.—Motion of charged particles in a nonneutral plasma —E. N. Agafonova and L. I. Grechikhin. 19(11), 1488–9 (May 1975); CPM-7506X1242

Gridasov, V. I.—Efficiency of internal targets in the accelerator at the Institute of High–Energy Physics —V. I. Gridasov, K. P. Myznikov, and V. N. Chepegin. 19(7), 922–5 (Jan. 1975); CPM-7503X0810

Grigor'ev, V. P.—Nonmonoenergetic relativistic electron beam in a bounded collisional plasma —V. P. Grigor'ev and N. S. Shulaev. 19(1), 20–1 (Jul. 1974); CPM-7407X1532

Grin', Yu. I.—N_2O–N_2–He gasdynamic laser —Yu. I. Grin' and V. G. Testov. 19(7), 975 (Jan. 1975); CPM-7503X0863

Grinberg, G. A.—Two–dimensional diffraction on a system of straight segments (shields) —G. A. Grinberg. 19(5), 581–5 (Nov. 1974); CPM-7501X0375

—Heat transport problems with time-varying boundary conditions or moving boundaries (Stefan problem) —G. A. Grinberg. 19(10), 1267–72 (Apr. 1975); CPM-7506X0201

Grishaev, I. A.—Self-acceleration of an intense electron beam —I. A. Grishaev, A. N. Dedik, V. V. Zakutin, I. I. Magda, Yu. V. Tkach, and A. M. Shenderovich. 19(8), 1087–9 (Feb. 1975); CPM-7504X1511

Grishin, S. D.—Ion-optical system for shaping high-current ion beams —S. D. Grishin, V. F. Kuzovlev, R. V. Orlov, and S. N. Ogorodnikov. 19(11), 1462–4 (May 1975); CPM-7506X1216

Gryzlov, A. I.—Linear accelerator for beam injection into a slowly rising magnetic field —D. G. Borisov, A. I. Gryzlov, V. M. Levin, and A. V. Ryabtsov. 19(4), 509–10 (Oct. 1974); CPM-7412X0293

Gubarev, V. F.—Distributed systems for feedback control of a tokamak plasma —V. F. Gubarev and Yu. I. Samoilenko. 19(4), 463–7 (Oct. 1974); CPM-7412X0247

Gulyaev, S. N.—Frequency locking in a 3.39μ laser —E. Yu. Andreeva, S. N. Gulyaev, and D. K. Terekhin. 19(12), 1620–1 (Jun. 1975); CPM-7508X0494

Gurevich, G. L.—Magnetoacoustic transducer based on the domain structure of a ferromagnetic material —G. L. Gurevich and G. A. Vul'gal'ter. 19(1), 154–5 (Jul. 1974); CPM-7407X1666

Gurevich, M. A.—Rate for evaporation of a liquid into vacuum —A. P. Andreev and M. A. Gurevich. 19(3), 396–401 (Sep. 1974); CPM-7412X1082

Gurevich, S. B.—Reversibility of chalcogenide materials in holography —S. B. Gurevich, N. N. Il'yashenko, B. T. Kolomiets, V. M. Lyubin, and M. V. Sukharev. 19(1), 152–3 (Jul. 1974); CPM-7407X1664

Gusev, O. A.—Beam focusing in an accelerator with inductive energy storage —V. A. Glukhikh, O. A. Gusev, E. G. Komar, V. S. Kuznetsov, M. P. Svin'in, and R. P. Fidel'skaya. 19(3), 366–7 (Sep. 1974); CPM-7412X1052

—High–current pulsed electron accelerator with an annular beam —M. I. Avramenko, V. A. Glukhikh, O. A. Gusev, E. G. Komar, O. L. Komarov, V. S. Kuznetsov, A. S. Perlin, and M. P. Svin'in. 19 (3), 368–70 (Sep. 1974); CPM-7412X1054

—Inductive energy storage in pulsed accelerators —V. A. Glukhikh, O. A. Gusev, E. G. Komar, and M. P. Svin'in. 19(5), 660–1 (Nov. 1974); CPM-7501X0454

—Shaping of voltage pulses by discharging an inductive storage bank with a charged-particle beam —O. A. Gusev, E. G. Komar, V. B. Markov, and E. M. Mellekh. 19(5), 662–3 (Nov. 1974); CPM-7501X0456

Guseva, L. G.—Effect of electron reflection on the voltage-current characteristics of a high-voltage, hollow-cathode, glow discharge —Ya. Ya. Udris, V. A. Chernov, and L. G. Guseva. 19(1), 134–5 (Jul. 1974); CPM-7407X1646

Guseva, M. B.—Efficient ion source —D. Kh. Abdrashitova, V. G. Babaev, and M. B. Guseva. 19(2), 264–6 (Aug. 1974); CPM-7408X1528

Gus'kov, Yu. K.—Effect of selenium and sulfur on the work function of tungsten —N. V. Volkov, Yu. K. Gus'kov, Z. N. Kononova, and Yu. I. Kostikov. 19(1), 144–5 (Jul. 1974); CPM-7407X1656

—Steady-state operation of a surface-ionization thermionic converter —N. V. Volkov, Yu. K. Gus'kov, Yu. I. Kostikov, and V. P. Pashchenko. 19(8), 1129–30 (Feb. 1975); CPM-7504X1553

Gutarev, Yu. V.—Magnetodrift waves in a finite-β plasma —N. M. Ryzhov, V. L. Sizonenko, V. A. Suprunenko, E. A. Sukhomlin, and Yu. V. Gutarev. 19(6), 722–5 (Dec. 1974); CPM-7501X0722

I

Igritskii, A. N.—Aperiodic instability in a plasma gap with external feedback —A. N. Igritskii. 19(6), 719–21 (Dec. 1974); CPM-7501X0719

Il'inskii, V. A.—Laser compensation for thermal distortion in optical pumping —V. K. Zaitsev, V. A. Il'inskii, A. M. Marugin, and V. M. Ovchinnikov. 19(11), 1480–1 (May 1975); CPM-7506X1234

Il'yashenko, N. N.—Reversibility of chalcogenide materials in holography —S. B. Gurevich, N. N. Il'yashenko, B. T. Kolomiets, V. M. Lyubin, and M. V. Sukharev. 19(1), 152–3 (Jul. 1974); CPM-7407X1664

Imas, Ya. A.—Optical characteristics of K-8 glass subject to radiation from a neodymium laser —A. M. Bonch-Bruevich, Ya. A. Imas, V. S. Salyadinov, and A. V. Shatilov. 19(2), 287–9 (Aug. 1974); CPM-7408X1551

—Surface evaporation of a solid transparent dielectric under the action of laser radiation —A. M. Bonch-Bruevich, Ya. A. Imas, A. A. Kovalev, P. S. Kondratenko, and B. I. Makshantsev. 19(11), 1474–6 (May 1975); CPM-7506X1228

Indykul, V. P.—Nonlinear interaction between a monochromatic ion-acoustic wave and a plasma —V. P. Indykul. 19(9), 1157–9 (Mar. 1975); CPM-7505X0579

Ioffe, I. V.—Convection in a liquid dielectric in a longitudinal electric field —I. V. Ioffe and N. V. Kalinin. 19(5), 692 (Nov. 1974); CPM-7501X0486

—Liquid crystals in external fields —I. V. Ioffe. 19(8), 1012–5 (Feb. 1975); CPM-7504X1436

—Theory of nonequilibrium shock waves —R. A. Glatman and I. V. Ioffe. 19(11), 1482–3 (May 1975); CPM-7506X1236

Ionov, N. I.—Displacement of ion-current retardation curves in surface ionization in a strong field —N. I. Ionov. 19(1), 146–7 (Jul. 1974); CPM-7407X1658

Iremashvili, D. V.—Low-frequency oscillations in counter-streaming high-current electron beams —A. F. Timoshenko, D. V. Iremashvili, and Yu. K. Udovichenko. 19(8), 1038–41 (Feb. 1975); CPM-7504X1462

—Wave excitation at half the gyrofrequency in counterstreaming electron beams —A. P. Timoshenko, D. V. Iremashvili, and Yu. K. Udovichenko. 19(12), 1584–6 (Jun. 1975); CPM-7508X0458

Irisova, N. A.—Dielectric properties of foamed ceramics at millimeter wavelengths —N. A. Irisova, G. V. Kozlov, V. E. Mandrusov, B. S. Cherepanov, and I. M. Chernyshev. 19(1), 103–4 (Jul. 1974); CPM-7407X1615

—Temperature dependence of the dielectric permittivity of single-crystal TiO_2 in the submillimeter range —A. A. Volkov, N. A. Irisova, and G. V. Kozlov. 19(4), 567–8 (Oct. 1974); CPM-7412X0351

Istomin, V. V.—Linear transient response of a fully ionized plasma in a pulsed electric field —V. V. Istomin, S. P. Sher, and S. P. Dovgopol. 19(7), 963–4 (Jan. 1975); CPM-7503X0851

Istomin, Ya. N.—Nonlinear instability of a helicon packet in an anisotropic plasma —Ya. N. Istomin and V. I. Karpman. 19(3), 405–6 (Sep. 1974); CPM-7412X1091

—Evolution of monochromatic whistler and plasma-wave packets in a collisionless plasma —Ya. N. Istomin. 19(4), 529–30 (Oct. 1974); CPM-7412X0313

Ivakin, B. A.—Temperature dependence of trace diffusion coefficients of certain gases —A. É. Loiko, B. A. Ivakin, and P. E. Suetin. 19 (3), 434 (Sep. 1974); CPM-7412X1120

Ivanov, A. P.—Measurement of statistical parameters of scattering particles in laminar flow by Doppler spectroscopy —A. P. Ivanov, A. Ya. Khairullina, and A. P. Chaikovski. 19(2), 267–70 (Aug. 1974); CPM-7408X1531

Ivanov, M. I.—Acceleration of plasma electrons in strong electric fields —Z. A. Al'bikov, M. I. Ivanov, V. I. Kazacha, O. V. Kozlov, V. D. Rusanov, and S. S. Sobolev. 19(11), 1498–9 (May 1975); CPM-7506X1252

Ivanov, S. A.—Development of an inhibited glow discharge —Yu. A. Bystrov, S. A. Ivanov, and Yu. F. Radchenko. 19(11), 1447–8 (May 1975); CPM-7506X1201

Ivanov, V. G.—Possible use of the schlieren method to measure characteristics of turbulence —V. G. Ivanov. 19(3), 429–31 (Sep. 1974); CPM-7412X1115

—Statistical characteristics of the turbulent wake behind a supersonic sphere —V. G. Ivanov, G. I. Mishin, and S. N. Palkin. 19(4), 543–5 (Oct. 1974); CPM-7412X0327

Ivanov, V. I.—Radiation yield of ions in liquid dielectrics as a function of temperature and radiation energy —V. I. Ivanov, E. D. Kleshchenko, Yu. P. Sukhanovskii, and V. V. Frolov. 19(11), 1468–70 (May 1975); CPM-7506X1222

Ivanov, V. P.—Gas-kinetic removal of neutral molecules from an ion beam —V. P. Ivanov. 19(2), 239–42 (Aug. 1974); CPM-7408X1503

Izokh, V. V.—Aberrations in systems with plane and spherical detection apertures —V. V. Izokh, A. V. Sergeev, and I. Yu. Shmidov. 19(9), 1177–80 (Mar. 1975); CPM-7505X0599

K

Kagan, M. B.—Dependence of the basic parameters of $Al_xGa_{1-x}As$—GaAs solar converters on temperature and optical intensity —E. B. Vinogradova, M. B. Kagan, N. S. Koroleva, T. L. Lyubashevskaya, and T. A. Nuller. 19(10), 1378–81 (Apr. 1975); CPM-7506X0312

Kagan, Yu. M.—Effect of cathode emission on the threshold for striations —N. A. Vorob'eva, Yu. M. Kagan, V. M. Milenin, and A. Kh. Muradov. 19(1), 117–8 (Jul. 1974); CPM-7407X1629

—Electron energy distribution in the afterglow. I —A. B. Blagoev, Yu. M. Kagan, N. B. Kolokolov, and R. I. Lyagushchenko. 19(2), 211–4 (Aug. 1974); CPM-7408X1475

—Electron energy distribution in the afterglow. II —A. B. Blagoev, Yu. M. Kagan, N. B. Kolokolov, and R. I. Lyagushchenko. 19(2), 215–9 (Aug. 1974); CPM-7408X1479

—Electron energy distribution in a high-freqeuncy discharge in an axial magnetic field —S. D. Vagner, V. A. Virolainen, Yu. M. Kagan, and T. A. Kalmykova. 19(2), 290–1 (Aug. 1974); CPM-7408X1554

—Theory of the positive column in neon —Yu. B. Golobovskii, Yu. M. Kagan, and R. I. Lyagushchenko. 19(3), 335–9 (Sep. 1974); CPM-7412X1021

—High-frequency discharge in a mercury—helium mixture —S. D. Vagner, Yu. M. Kagan, A. I. Konstantinov, and I. S. Niskonen. 19 (7), 898–900 (Jan. 1975); CPM-7503X0786

—Electron energy distribution in a constricted, low-pressure hydrogen discharge —M. A. Abroyan, Yu. M. Kagan, N. B. Kolokolov, and B. P. Lavrov. 19(11), 1492–3 (May 1975); CPM-7506X1246

—Gas temperature in the positive column of a medium-β helium discharge —Yu. M. Kagan and K. K. Paskalev. 19(12), 1601–3 (Jun. 1975); CPM-7508X0475

—Temperature and electron density in the positive column of a medium-pressure helium discharge —Yu. M. Kagan and K. K. Paskalev. 19(12), 1604–5 (Jun. 1975); CPM-7508X0478

Kakichashvili, Sh. D.—Holography of raster objects —Sh. D. Kakichashvili. 19(5), 696–7 (Nov. 1974); CPM-7501X0490

Kaladze, T. D.—Excitation of electromagnetic ion cyclotron waves by fast ions —T. D. Kaladze, D. G. Lominadze, and K. N. Stepanov. 19(2), 175–6 (Aug. 1974); CPM-7408X1439

Kalashnikov, V. K.—Low-pressure self-maintained discharge with suppressed electron drift. I —V. K. Kalashnikov and Yu. V. Sanochkin. 19(12), 1549–53 (Jun. 1975); CPM-7508X0423

—Low-pressure self-maintained discharge with suppressed electron drift. II —Yu. V. Sanochkin and V. K. Kalashnikov. **19**(12), 1554–8 (Jun. 1975); CPM-7508X0428

Kalinichenko, A. I.—Excitation of thermoelastic vibrations of a thin plate by a beam of fast charged particles —A. I. Kalinichenko and V. T. Lazurik-Él'tsufin. **19**(10), 1382–3 (Apr. 1975); CPM-7506X0316

Kalinin, N. V.—Convection in a liquid dielectric in a longitudinal electric field —I. V. Ioffe and N. V. Kalinin. **19**(5), 692 (Nov. 1974); CPM-7501X0486

Kalinin, V. N.—Lasing properties of Yb^{3+} and Er^{3+} glass laser pumped by a laser —V. N. Kalinin, A. A. Mak, D. S. Prilezhaev, and V. A. Fromzel'. **19**(6), 835–6 (Dec. 1974); CPM-7501X0835

Kalmykova, S. S.—Conversion of regular charge–density waves in a inhomogeneous plasma —S. S. Kalmykova and A. P. Tolstoluzhskii. **19**(4), 455–8 (Oct. 1974); CPM-7412X0239

Kalmykova, T. A.—Electron energy distribution in a high–freqeuncy discharge in an axial magnetic field —S. D. Vagner, V. A. Virolainen, Yu. M. Kagan, and T. A. Kalmykova. **19**(2), 290–1 (Aug. 1974); CPM-7408X1554

Kalyatskii, I. I.—Electrical breakdown of vacuum gaps under superhigh voltage pulses —I. I. Kalyatskii, G. M. Kassirov, and G. V. Smirnov. **19**(11), 1434–5 (May 1975); CPM-7506X1188

Kamenev, A. G.—Surface–ionization determination of the electron affinities of silver and gold —É. Ya. Zandberg, A. G. Kamenev, and V. I. Paleev. **19**(3), 385–9 (Sep. 1974); CPM-7412X1071

—Determination of ionization potentials and electron affinities of certain elements by extrapolation —A. G. Kamenev, É. Ya. Zandberg, and V. I. Paleev. **19**(7), 940–1 (Jan. 1975); CPM-7503X0828

Kamenskii, E. I.—Spontaneous mode locking in a laser with a multifaceted element —E. I. Kamenskii and V. V. Kozlov. **19**(6), 831–2 (Dec. 1974); CPM-7501X0831

Kanaev, B. I.—Measurement of plasma ion temperature by a thin probe with $T_i \gtrsim T_e$ —B. I. Kanaev and E. E. Yushmanov. **19**(4), 554–5 (Oct. 1974); CPM-7412X0338

—Measurement of plasma electron temperature with a sinusoidal probe potential —B. I. Kanaev, V. V. Piterskii, and E. E. Yushmanov. **19**(11), 1421–3 (May 1975); CPM-7506X1175

Kapinos, V. N.—Electron lifetimes in atmosphere at high pressure —V. N. Kapinos, Yu. A. Medvedev, N. N. Morozov, and B. M. Stepanov. **19**(11), 1507 (May 1975); CPM-7506X1261

Kapranov, V. N.—Local–potential study of the Bénard problem in a homogeneous magnetic field —A. I. Lopushanskaya and V. N. Kapranov. **19**(5), 612–4 (Nov. 1974); CPM-7501X0406

Karachevtsev, G. V.—Steady-state electron density in photoionizion of aerosol particles —G. V. Karachevtsev and A. A. Fridman. **19**(11), 1471–3 (May 1975); CPM-7506X1225

Karimkhodzhaev, I.—Electrical explosion of the metastable liquid phases of zinc, cadmium, and lead —M. M. Martynyuk and I. Karimkhodzhaev. **19**(11), 1454–7 (May 1975); CPM-7506X1208

—Resistance and enthalpy of refractory exploding wires —M. M. Martynyuk, I. Karimkhodzhaev, and V. I. Tsapkov. **19**(11), 1458–61 (May 1975); CPM-7506X1212

Karizhskii, A. P.—End current in a magnetron with a secondary–emission cathode —G. G. Sominskii, S. A. Fridrikhov, O. Yu. Tsybin, and A. P. Karizhskii. **19**(3), 378–81 (Sep. 1974); CPM-7412X1064

Karnaukhova, N. M.—Evaporation rates of the system ZrC+x%W for the temperature range 2300-3000°K —N. M. Karnaukhova, V. A. Luknitskii, and I. A. Maslov. **19**(8), 1096–9 (Feb. 1975); CPM-7504X1520

Karpman, V. I.—Nonlinear instability of a helicon packet in an anisotropic plasma —Ya. N. Istomin and V. I. Karpman. **19**(3), 405–6 (Sep. 1974); CPM-7412X1091

Karpukhin, V. I.—Plasma equilibrium and confinement in a poloidal heliotron configuration. I —V. G. Zykov, V. I. Karpukhin, Yu. F. Lonin, N. N. Podteregera, N. I. Rudnev, and V. T. Tolok. **19**(8), 1063–8 (Feb. 1975); CPM-7504X1487

—Plasma equilibrium and confinement in a poloidal heliotron configuration. II —V. G. Zykov, V. I. Karpukhin, Yu. F. Lonin, N. N. Podteregera, N. I. Rudnev, A. Y. Skibenko, V. T. Tolok, and I. P. Fomin. **19**(8), 1069–72 (Feb. 1975); CPM-7504X1493

Kassirov, G. M.—Electrical breakdown of vacuum gaps under superhigh voltage pulses —I. I. Kalyatskii, G. M. Kassirov, and G. V. Smirnov. **19**(11), 1434–5 (May 1975); CPM-7506X1188

Kasumov, M. M.—Electron–beam excited crossed–field discharge —V. A. Saenko and M. M. Kasumov. **19**(6), 759–61 (Dec. 1974); CPM-7501X0759

Katsubo, L. P.—Instabilities in interpenetrating electron and ion beams —I. A. Soloshenko and L. P. Katsubo. **19**(10), 1317–20 (Apr. 1975); CPM-7506X0251

—Measurement of ion density by the dispersion relation for an ion-beam plasma —M. D. Gabovich, L. P. Katsubo, and I. A. Soloshenko. **19**(11), 1412–3 (May 1975); CPM-7506X1166

Kaufman, R. N.—Rotation of Poynting vector for ultralow-frequency ion waves in an inhomogeneous plasma —Ya. L. Al'pert and R. N. Kaufman. **19**(12), 1519–21 (Jun. 1975); CPM-7508X0393

Kazacha, V. I.—Acceleration of plasma electrons in strong electric fields —Z. A. Al'bikov, M. I. Ivanov, V. I. Kazacha, O. V. Kozlov, V. D. Rusanov, and S. S. Sobolev. **19**(11), 1498–9 (May 1975); CPM-7506X1252

Kel'man, V. M.—A transaxial lens —V. M. Kel'man, L. M. Nazarenko, and E. M. Yakushev. **19**(4), 523–5 (Oct. 1974); CPM-7412X0307

—Theory of the cathode lens. III. Derivation of equations for composite cathode lenses —V. M. Kel'man, A. A. Sapargaliev, and E. M. Yakushev. **19**(5), 592–6 (Nov. 1974); CPM-7501X0386

—Theory of the cathode lens. IV. Aberrations of composite cathode lens —V. M. Kel'man, A. A. Sapargaliev, and E. M. Yakushev. **19**(5), 597–9 (Nov. 1974); CPM-7501X0391

—Symmetric multielectrode tubular electrostatic lenses —L. G. Glikman, V. M. Kel'man, and M. Sh. Nurmanov. **19**(5), 680–2 (Nov. 1974); CPM-7501X0474

Kerbelev, M. P.—Crystal defects of heterostructures of AlAs–GaAs solid solutions and effect on the characteristics of injection lasers —L. V. Druzhinina, V. T. Bublik, L. M. Dolginov, P. G. Eliseev, M. P. Kerbelev, V. B. Osvenskii, I. Z. Pinsker, and M. G. Shumskii. **19**(7), 935–9 (Jan. 1975); CPM-7503X0823

Khachatryan, A. M.—Nonlinear spherical aberrations and thermoelastic stresses in thermal self–focusing —A. A. Vigasin, Yu. A. Gorokhov, A. P. Sukhorukov, and A. M. Khachatryan. **19**(5), 673–5 (Nov. 1974); CPM-7501X0467

Khairullina, A. Ya.—Measurement of statistical parameters of scattering particles in laminar flow by Doppler spectroscopy —A. P. Ivanov, A. Ya. Khairullina, and A. P. Chaikovski. **19**(2), 267–70 (Aug. 1974); CPM-7408X1531

Khakimov, F. Kh.—Nonlinear statistical theory of a condensate of plasmons. II. Stochastic heating of plasma ions by large–scale Langmuir turbulence —F. Kh. Khakimov. **19**(3), 315–8 (Sep. 1974); CPM-7412X1001

—Excitation of acoustic waves by ion–acoustic turbulence —Kh. O. Abdulloev, F. Kh. Khakimov, and V. G. Makhan'kov. **19**(4), 441–5 (Oct. 1974); CPM-7412X0225

—Linear theory for the low–frequency electromagnetic properties of an isotropic turbulent plasma —K. Komilov, F. Kh. Khakimov, and V. N. Tsytovich. **19**(5), 615–7 (Nov. 1974); CPM-7501X0409

—Nonlinear statistical theory for condensation of Langmuir plasmons. III. Energy flux for plasma turbulence —F. Kh. Khakimov and V. N. Tsytovich. **19**(10), 1300–2 (Apr. 1975); CPM-7506X0234

Khaleev, M. M.—Unidirectional cw oscillation in a solid state ring laser with a return mirror —A. A. Mak, V. I. Ustyugov, V. A. Fromzel', and M. M. Khaleev. **19**(4), 552–3 (Oct. 1974); CPM-7412X0336

Khandurov, N. V.—Investigation of ionization processes behind strong shock waves using an electrical conductivity probe —V. A. Tishchenko, N. V. Khandurov, and É. K. Chekalin. **19**(5), 651–3 (Nov. 1974); CPM-7501X0445

Khayutin, L. M.—Nonlinear polarizability of a gaseous medium in a longitudinal magnetic field —V. A. Sokolov and L. M. Khayutin. **19**(5), 589–91 (Nov. 1974); CPM-7501X0383

Khazov, L. D.—Cumulative destruction of transparent dielectrics in repeated laser irradiation —L. D. Khazov, I. A. Fersman, and V. Yu. Bortniker. **19**(9), 1256–7 (Mar. 1975); CPM-7505X0678

Khirnyi, Yu. M.—Dielectric strength of a vacuum gap with electrodes irradiated with He^+ and H^+ ions —A. P. Solodovnikov and Yu. M. Khirnyi. **19**(8), 1122 (Feb. 1975); CPM-7504X1546

Khizhnyak, N. A.—Resonance properties of a pulsating dielectric sphere —A. G. Nerukh and N. A. Khizhnyak. **19**(2), 166–8 (Aug. 1974); CPM-7408X1430

—Diffraction of electromagnetic waves by a dielectric wedge —A. A. Aleksandrova and N. A. Khizhnyak. **19**(11), 1385–9 (May 1975); CPM-7506X1139

—Correction to the paper "Resonant properties of a pulsating dielectric sphere" —A. G. Nerukh and N. A. Khizhnyak. 19(12), 1641 (Jun. 1975); CPM-7508X0515

Khokhlov, R. V.—Gas cooling in transmission of high-power CO_2 laser radiation through the atmosphere —B. F. Gordiets, A. I. Osipov, and R. V. Khokhlov. 19(5), 669–72 (Nov. 1974); CPM-7501X0463

Kholodenko, M. A.—Proton extraction from the 70–GeV accelerator for the Ludmila liquid-hydrogen chamber (extraction system S) —A. A. Aseev, A. I. Drozhdin, B. A. Zelenov, É. A. Merker, L. L. Moizhes, K. P. Myznikov, A. A. Roshchin, V. M. Tatarenko, M. A. Kholodenko, A. D. Artemov, L. N. Vaulin, V. I. Gordin, I. I. Kovalevskii, V. N. Rozhkov, M. M. Suvorov, A. S. Sudarushkin, and V. I. Chuiko. 19(1), 70–6 (Jul. 1974); CPM-7407X1582

Kholodnykh, A. I.—Direct and cascade four-photon parametric scattering of light in $LiIO_3$ crystals —S. M. Arakelyan, V. G. Tunkin, A. I. Kholodnykh, and A. S. Chirkin. 19(6), 787–92 (Dec. 1974); CPM-7501X0787

Khudyakova, L. N.—Fast electrons and x rays from nanosecond gas discharges at 0.1–760 torr —L. V. Tarasova, L. N. Khudyakova, T. V. Loiko, and V. A. Tsukerman. 19(3), 351–3 (Sep. 1974); CPM-7412X1037

Khuzeev, A. P.—Ionization and recombination coefficients in a discharge excited by fast electrons —Yu. I. Bychkov, Yu. D. Korolev, and A. P. Khuzeev. 19(1), 140–1 (Jul. 1974); CPM-7407X1652

Khvesyuk, V. I.—Microcells in cold cathodes —N. P. Kozlov, A. A. Lyapin, and V. I. Khvesyuk. 19(8), 1093–5 (Feb. 1975); CPM-7504X1517

—Formation of a plasma focus in a plasma erosion accelerator. II. Energy characteristics of the dense plasma focus —N. P. Kozlov, L. V. Leskov, Yu. S. Protasov, and V. I. Khvesyuk. 19(12), 1558–9 (Jun. 1975); CPM-7508X0432

Khyuppenen, A. P.—Parasitic amplitude modulation of a stabilized Nd^{3+}:YAG laser —N. M. Galaktionova, A. A. Mak, and A. P. Khyuppenen. 19(4), 486–90 (Oct. 1974); CPM-7412X0270

—Solid-state laser with externally forced *Q* switching —N. M. Galaktionova, A. A. Mak, and A. P. Khyuppenen. 19(9), 1174–6 (Mar. 1975); CPM-7505X0596

Kichaev, V. I.—Flow of low-density gases in a capillary grid —B. T. Porodnov, V. D. Akin'shin, V. I. Kichaev, S. F. Borisov, and P. E. Suetin. 19(4), 515–8 (Oct. 1974); CPM-7412X0299

Kingsep, A. S.—Scattering of an electron beam in a straight *dc* turbulent plasma —Yu. P. Golovanov, L. P. Zakatov, A. S. Kingsep, and A. G. Plakhov. 19(8), 1046–9 (Feb. 1975); CPM-7504X1470

Kirichenko, G. S.—Plasma synthesis by injection of an electron beam through an ion source —V. F. Virko, M. D. Gabovich, G. S. Kirichenko, and O. K. Nazarenko. 19(11), 1418–20 (May 1975); CPM-7506X1172

Kitsenko, A. B.—Parametric plasma instabilities excited by the sudden application of an electric field —A. B. Kitsenko and K. N. Stepanov. 19(1), 127–8 (Jul. 1974); CPM-7407X1639

—Nonlinear behavior of monochromatic surface waves excited by a beam —A. B. Kitsenko, I. M. Pankratov, and K. N. Stepanov. 19 (11), 1505–6 (May 1975); CPM-7506X1259

Klapchenko, V. I.—Effect of molecular hydrogen on a cesium discharge. I —N. D. Morgulis and V. I. Klapchenko. 19(7), 911–3 (Jan. 1975); CPM-7503X0799

Kleshchenko, E. D.—Radiation yield of ions in liquid dielectrics as a function of temperature and radiation energy —V. I. Ivanov, E. D. Kleshchenko, Yu. P. Sukhanovskii, and V. V. Frolov. 19(11), 1468–70 (May 1975); CPM-7506X1222

Klimovskii, Yu. A.—Mass spectrum of secondary ions ejected from the surface of a single crystal of gallium arsenide by argon ions —A. G. Koval', V. V. Bobkov, Yu. A. Klimovskii, S. S. Strel'chenko, V. V. Shubina, V. V. Lebedev, and Ya. M. Fogel'. 19(12), 1587–9 (Jun. 1975); CPM-7508X0461

Klyushkin, P. A.—Effect of instrumental noise on a system with two spin oscillators using Cs^{133} and He^3 —R. A. Zhitnikov, V. V. Semenov, and P. A. Klyushkin. 19(4), 556–7 (Oct. 1974); CPM-7412X0340

Kolesnikov, A. A.—Correlation analysis of fine-structure images —A. A. Kolesnikov and N. V. Lapteva. 19(9), 1181–4 (Mar. 1975); CPM-7505X0603

Kolokolov, N. B.—Electron energy distribution in the afterglow. I —A. B. Blagoev, Yu. M. Kagan, N. B. Kolokolov, and R. I. Lyagushchenko. 19(2), 211–4 (Aug. 1974); CPM-7408X1475

—Electron energy distribution in the afterglow. II —A. B. Blagoev, Yu. M. Kagan, N. B. Kolokolov, and R. I. Lyagushchenko. 19(2), 215–9 (Aug. 1974); CPM-7408X1479

—Electron energy distribution in a constricted, low-pressure hydrogen discharge —M. A. Abroyan, Yu. M. Kagan, N. B. Kolokolov, and B. P. Lavrov. 19(11), 1492–3 (May 1975); CPM-7506X1246

Kolomiets, B. T.—Reversibility of chalcogenide materials in holography —S. B. Gurevich, N. N. Il'yashenko, B. T. Kolomiets, V. M. Lyubin, and M. V. Sukharev. 19(1), 152–3 (Jul. 1974); CPM-7407X1664

Kolotilin, B. I.—Efficiency of the scattering of "unstable" charged particles in quadrupole mass spectrometers —É. P. Sheretov, B. I. Kolotilin, and M. P. Safonov. 19(12), 1622–4 (Jun. 1975); CPM-7508X0496

Komar, E. G.—Beam focusing in an accelerator with inductive energy storage —V. A. Glukhikh, O. A. Gusev, E. G. Komar, V. S. Kuznetsov, M. P. Svin'in, and R. P. Fidel'skaya. 19(3), 366–7 (Sep. 1974); CPM-7412X1052

—High-current pulsed electron accelerator with an annular beam —M. I. Avramenko, V. A. Glukhikh, O. A. Gusev, E. G. Komar, O. L. Komarov, V. S. Kuznetsov, A. S. Perlin, and M. P. Svin'in. 19 (3), 368–70 (Sep. 1974); CPM-7412X1054

—Inductive energy storage in pulsed accelerators —V. A. Glukhikh, O. A. Gusev, E. G. Komar, and M. P. Svin'in. 19(5), 660–1 (Nov. 1974); CPM-7501X0454

—Shaping of voltage pulses by discharging an inductive storage bank with a charged-particle beam —O. A. Gusev, E. G. Komar, V. B. Markov, and E. M. Mellekh. 19(5), 662–3 (Nov. 1974); CPM-7501X0456

Komarov, O. L.—High-current pulsed electron accelerator with an annular beam —M. I. Avramenko, V. A. Glukhikh, O. A. Gusev, E. G. Komar, O. L. Komarov, V. S. Kuznetsov, A. S. Perlin, and M. P. Svin'in. 19(3), 368–70 (Sep. 1974); CPM-7412X1054

—Estimate of the angular divergence in intense electron beams —V. S. Kuznetsov, Yu. P. Vakhrushin, O. L. Komarov, and R. P. Fidel'skaya. 19(7), 868–70 (Jan. 1975); CPM-7503X0756

Komarov, V. N.—Mass-spectrometer study of the ion composition of a glow discharge —N. P. Egorov and V. N. Komarov. 19(8), 1100–2 (Feb. 1975); CPM-7504X1524

Komarov, V. S.—Quenching in the CF_3I photodissociation laser —G. A. Skorobogatov, V. M. Tret'yak, and V. S. Komarov. 19(4), 495–8 (Oct. 1974); CPM-7412X0279

—Method for determining the absolute characteristics of CF_3I laser emission —V. S. Komarov, V. G. Seleznev, and G. A. Skorobogatov. 19(4), 558–60 (Oct. 1974); CPM-7412X0342

—Absolute-photometry determination of the rate constant of the gas-phase reaction of the radical compound C_3F_7 and $I(^2P_{3/2})$ —G. A. Skorobogatov, V. S. Komarov, and V. G. Seleznev. 19(9), 1239–41 (Mar. 1975); CPM-7505X0661

Komilov, K.—Linear theory for the low-frequency electromagnetic properties of an isotropic turbulent plasma —K. Komilov, F. Kh. Khakimov, and V. N. Tsytovich. 19(5), 615–7 (Nov. 1974); CPM-7501X0409

Komolov, V. L.—Variational analysis of thermal breakdown of a semiconductor irradiated by light —V. L. Komolov. 19(5), 600–2 (Nov. 1974); CPM-7501X0394

Kompaniets, T. N.—Effects of cleaning on adsorption by germanium single crystals —Yu. I. Belyakov, M. P. Volkov, and T. N. Kompaniets. 19(6), 815–6 (Dec. 1974); CPM-7501X0815

Kondrashov, V. E.—Recombination in an expanding plasma —Yu. A. Bykovskii, N. N. Degtyarenko, V. F. Elesin, V. E. Kondrashov, E. E. Lovetskii, A. N. Polyanichev, and V. S. Fetisov. 19(1), 43–8 (Jul. 1974); CPM-7407X1555

Kondratenko, A. N.—Second-harmonic generation and emission in wave conversion at a plasma boundary —A. N. Kondratenko, V. G. Shaptala, and V. M. Kuklin. 19(1), 22–4 (Jul. 1974); CPM-7407X1534

—Conversion of an electromagnetic wave into an ion-acoustic wave in an inhomogeneous plasma —A. N. Kondratenko and V. M. Kuklin. 19(1), 25–7 (Jul. 1974); CPM-7407X1537

—Damping of ion-acoustic waves in a bounded plasma —A. N. Kondratenko and V. M. Kuklin. 19(3), 326–8 (Sep. 1974); CPM-7412X1012

Kondratenko, P. S.—Surface evaporation of a solid transparent dielectric under the action of laser radiation —A. M. Bonch-Bruevich, Ya. A. Imas, A. A. Kovalev, P. S. Kondratenko, and B. I. Makshantsev. 19(11), 1474–6 (May 1975); CPM-7506X1228

Kononova, Z. N.—Effect of selenium and sulfur on the work function of tungsten —N. V. Volkov, Yu. K. Gus'kov, Z. N. Kononova, and Yu. I. Kostikov. 19(1), 144–5 (Jul. 1974); CPM-7407X1656

Konov, V. I.—Electrical conductivity of a pseudoliquefied layer in an electric field —V. V. Gal', V. I. Konov, and K. A. Nikitin. 19(9), 1214–5 (Mar. 1975); CPM-7505X0636

Konovalov, V. G.—Electron temperature in a high-frequency helium discharge —V. S. Voitsenya, A. Yu. Voloshko, V. G. Konovalov, and S. I. Solodovchenko. 19(7), 909–10 (Jan. 1975); CPM-7503X0797

Konstantinov, A. I.—High-frequency discharge in a mercury—helium mixture —S. D. Vagner, Yu. M. Kagan, A. I. Konstantinov, and I. S. Niskonen. 19(7), 898–900 (Jan. 1975); CPM-7503X0786

Kop'ev, D. S.—Electroluminescence spectra of the red luminescnet diodes p–$Al_xGa_{1-x}As$—n–$AlyGa_{1-y}As(y>x)$ —V. M. Busov, D. Z. Garbuzov, A. T. Gorelenok, and D. S. Kop'ev. 19(12), 1598–600 (Jun. 1975); CPM-7508X0472

Korlyakov, E. D.—Capillary gravitational waves and the mechanogalvanic effect —E. D. Korlyakov. 19(7), 965 (Jan. 1975); CPM-7503X0853

Kornich, V. G.—Atomic recombination on a solid surface —V. P. Pinchuk, A. N. Gorban', and V. G. Kornich. 19(6), 808–10 (Dec. 1974); CPM-7501X0808

Kornyushkin, Yu. D.—Atomic diffusion from a finite film over a solid surface —Yu. D. Kornyushkin. 19(7), 971–2 (Jan. 1975); CPM-7503X0859

—Parallel-plate capacitor as a charged-particle spectrometer —Yu. D. Kornyushkin. 19(8), 1110–2 (Feb. 1975); CPM-7504X1534

Korolev, Yu. D.—Ionization and recombination coefficients in a discharge excited by fast electrons —Yu. I. Bychkov, Yu. D. Korolev, and A. P. Khuzeev. 19(1), 140–1 (Jul. 1974); CPM-7407X1652

—Energy input in electrical ionization lasers —Yu. I. Bychkov, Yu. D. Korolev, Yu. A. Kurbatov, and G. A. Mesyats. 19(4), 499–502 (Oct. 1974); CPM-7412X0283

Koroleva, N. S.—Dependence of the basic parameters of $Al_xGa_{1-x}As$—GaAs solar converters on temperature and optical intensity —E. B. Vinogradova, M. B. Kagan, N. S. Koroleva, T. L. Lyubashevskaya, and T. A. Nuller. 19(10), 1378–81 (Apr. 1975); CPM-7506X0312

Korol'kov, V. L.—Dielectric breakdown of detonation products —V. L. Korol'kov, M. A. Mel'nikov, and A. P. Tsyplenko. 19(12), 1569–70 (Jun. 1975); CPM-7508X0443

Koroteev, V. I.—Spatial and energy parameters of the relativistic electron beam of the Rius-5 accelerator —A. T. Altyntsev and V. I. Koroteev. 19(6), 773–4 (Dec. 1974); CPM-7501X0773

Koroza, V. I.—Parametric interaction of a charged particle beam with a periodic system —V. I. Koroza and E. S. Sukhovskii. 19(8), 1020–4 (Feb. 1975); CPM-7504X1444

Korsakov, V. V.—Multiple recording and erasure of optical information in certain glassy chalcogenides —V. V. Korsakov, V. I. Nalivaiko, V. G. Remesnik, and V. G. Tsukerman. 19(4), 565–6 (Oct. 1974); CPM-7412X0349

Korsun, A. G.—Current limiting by self magnetic field in a plasma accelerator —A. G. Korsun. 19(1), 124–6 (Jul. 1974); CPM-7407X1636

—Two modes of operation of an arc plasma source in an external magnetic field —A. G. Korsun and S. A. Meshcheryakov. 19(11), 1500–1 (May 1975); CPM-7506X1254

Kosarev, E. L.—Narrow-band decimeter radiation from lighting —E. L. Kosarev and Yu. G. Serezhkin. 19(2), 229–33 (Aug. 1974); CPM-7408X1493

Koshelev, V. I.—Electron energy spectrum in a high-current vacuum diode —S. P. Bugaev, V. I. Koshelev, and M. N. Timofeev. 19(9), 1193–5 (Mar. 1975); CPM-7505X0615

Kosov, N. D.—Steady-state study of the temperature dependence of the mutual-diffusion coefficients of certain gases —N. D. Kosov and B. P. Solonitsyn. 19(4), 541–2 (Oct. 1974); CPM-7412X0325

Kostikov, Yu. I.—Effect of selenium and sulfur on the work function of tungsten —N. V. Volkov, Yu. K. Gus'kov, Z. N. Kononova, and Yu. I. Kostikov. 19(1), 144–5 (Jul. 1974); CPM-7407X1656

—Steady-state operation of a surface-ionization thermionic converter —N. V. Volkov, Yu. K. Gus'kov, Yu. I. Kostikov, and V. P. Pashchenko. 19(8), 1129–30 (Feb. 1975); CPM-7504X1553

Kostin, A. A.—Theory of the low-voltage arc in a narrow gap —F. G. Baksht, A. A. Kostin, and V. A. Nemchinskii. 19(5), 654–7 (Nov. 1974); CPM-7501X0448

—Atomic density in the low-voltage arc in a cesium diode —F. G. Baksht, A. A. Kostin, Yu. L. Serov, and I. P. Yavor. 19(11), 1424–5 (May 1975); CPM-7506X1178

Kostin, V. M.—Power spectrum of potential fluctuations in a moving magnetoactive plasma —V. M. Kostin. 19(8), 1053–6 (Feb. 1975); CPM-7504X1477

Kostomarov, D. P.—Energy balance in Tokamaks in the "plateau—banana" transition region —Yu. N. Dnestrovskii and D. P. Kostomarov. 19(12), 1541–2 (Jun. 1975); CPM-7508X0415

Kostyuk, G. I.—Breakdown caused by electron bombardment of the surface of an alloy electrode —N. V. Belan, G. I. Kostyuk, and V. A. Pimkin. 19(6), 802–3 (Dec. 1974); CPM-7501X0802

Kotov, O. I.—Effect of a magnetic field on spontaneous mode-locking in a He—Ne laser $(\Lambda=0.63\mu)$ —V. Yu. Petrun'kin, V. M. Nikolaev, O. I. Kotov, and B. V. L'vov. 19(12), 1612–3 (Jun. 1975); CPM-7508X0486

Kotov, Yu. A.—High-power nanosecond electron accelerator with inductive storage —B. M. Koval'chuk, Yu. A. Kotov, and G. A. Mesyats. 19(1), 136–7 (Jul. 1974); CPM-7407X1648

Koval', A. G.—Mass spectrum of secondary ions ejected from the surface of a single crystal of gallium arsenide by argon ions —A. G. Koval', V. V. Bobkov, Yu. A. Klimovskii, S. S. Strel'chenko, V. V. Shubina, V. V. Lebedev, and Ya. M. Fogel'. 19(12), 1587–9 (Jun. 1975); CPM-7508X0461

Koval'chuk, B. M.—High-power nanosecond electron accelerator with inductive storage —B. M. Koval'chuk, Yu. A. Kotov, and G. A. Mesyats. 19(1), 136–7 (Jul. 1974); CPM-7407X1648

Kovalenko, V. G.—Electrostatic analyzer for wide beams —V. G. Kovalenko and B. V. Polenov. 19(4), 561–2 (Oct. 1974); CPM-7412X0345

Kovalenko, V. P.—Ion focusing of an electron beam in deep melting of a metal —M. D. Gabovich, V. P. Kovalenko, O. A. Metallov, O. K. Nazarenko, and S. K. Pats'ora. 19(7), 973–4 (Jan. 1975); CPM-7503X0861

—Laser-initiated vacuum discharge —V. P. Kovalenko, A. A. Makarevich, V. A. Rodichkin, and A. M. Timonin. 19(11), 1429–31 (May 1975); CPM-7506X1183

Kovalev, A. A.—Nonradiative electron transitions and thermal effects in laser-irradiated transparent dielectrics —B. I. Makshantsev, A. A. Kovalev, R. K. Leonov, and P. A. Yampol'skii. 19(1), 98–102 (Jul. 1974); CPM-7407X1610

—Surface evaporation of a solid transparent dielectric under the action of laser radiation —A. M. Bonch-Bruevich, Ya. A. Imas, A. A. Kovalev, P. S. Kondratenko, and B. I. Makshantsev. 19(11), 1474–6 (May 1975); CPM-7506X1228

Kovalevskii, I. I.—Proton extraction from the 70-GeV accelerator for the Ludmila liquid-hydrogen chamber (extraction system S) —A. A. Aseev, A. I. Drozhdin, B. A. Zelenov, É. A. Merker, L. L. Moizhes, K. P. Myznikov, A. A. Roshchin, V. M. Tatarenko, M. A. Kholodenko, A. D. Artemov, L. N. Vaulin, V. I. Gordin, I. I. Kovalevskii, V. N. Rozhkov, M. M. Suvorov, A. S. Sudarushkin, and V. I. Chuiko. 19(1), 70–6 (Jul. 1974); CPM-7407X1582

Kovnatskii, A. M.—Current-driven instability in a conducting fluid —A. M. Kovnatskii. 19(5), 691 (Nov. 1974); CPM-7501X0485

Kovrov, P. E.—Vacuum-UV and soft x-ray emission in a magnetoplasma compressor —P. E. Kovrov and L. G. Tokarev. 19 (4), 563–4 (Oct. 1974); CPM-7412X0347

Kozharin, A. A.—Plasma decay instability in crossed fields —V. I. Farenik, V. V. Vlasov, A. M. Rozhkov, and A. A. Kozharin. 19(8), 1116–7 (Feb. 1975); CPM-7504X1540

—Ion energy spectra and collective effects in a Penning ion source —V. I. Farenik, V. V. Vlasov, A. M. Rozhkov, and A. A. Kozharin. 19(9), 1258–9 (Mar. 1975); CPM-7505X0680

Kozlov, G. V.—Dielectric properties of foamed ceramics at millimeter wavelengths —N. A. Irisova, G. V. Kozlov, V. E. Mandrusov, B. S. Cherepanov, and I. M. Chernyshev. 19(1), 103–4 (Jul. 1974); CPM-7407X1615

—Temperature dependence of the dielectric permittivity of single-crystal TiO_2 in the submillimeter range —A. A. Volkov, N. A. Irisova, and G. V. Kozlov. 19(4), 567–8 (Oct. 1974); CPM-7412X0351

Kozlov, N. P.—Use of plasma accelerator for optical pumping of lasers —N. P. Kozlov and Yu. S. Protasov. 19(3), 358–60 (Sep. 1974); CPM-7412X1044

—Microcells in cold cathodes —N. P. Kozlov, A. A. Lyapin, and V. I. Khvesyuk. 19(8), 1093–5 (Feb. 1975); CPM-7504X1517

—Formation of a plasma focus in a plasma erosion accelerator. II. Energy characteristics of the dense plasma focus —N. P. Kozlov, L. V. Leskov, Yu. S. Protasov, and V. I. Khvesyuk. **19**(12), 1558–9 (Jun. 1975); CPM-7508X0432

Kozlov, O. V.—Acceleration of plasma electrons in strong electric fields —Z. A. Al'bikov, M. I. Ivanov, V. I. Kazacha, O. V. Kozlov, V. D. Rusanov, and S. S. Sobolev. **19**(11), 1498–9 (May 1975); CPM-7506X1252

Kozlov, V. V.—Spontaneous mode locking in a laser with a multifaceted element —E. I. Kamenskii and V. V. Kozlov. **19**(6), 831–2 (Dec. 1974); CPM-7501X0831

Kozyrev, A. N.—Plasma diffusion in the Tornado device —A. N. Kozyrev and B. P. Peregud. **19**(4), 468–74 (Oct. 1974); CPM-7412X0252

Kozyrev, A. V.—Effects of ion microfields on emission of an arc cathode —A. M. Dorodnov, V. B. Davydov, A. V. Kozyrev, and Ya. A. Pomelov. **19**(3), 390–3 (Sep. 1974); CPM-7412X1076

Krasnov, I. P.—The magnetostatic problem for thin closed shells —I. P. Krasnov. **19**(6), 711–2 (Dec. 1974); CPM-7501X0711

Krasov, V. I.—Connection of magnetic lines of force in a neutral layer —A. T. Altyntsev and V. I. Krasov. **19**(12), 1639–40 (Jun. 1975); CPM-7508X0513

Kremkov, M. V.—Energy losses of slow electrons reflected from molybdenum and tungsten single crystals —O. M. Artamonov, B. B. Bolotov, and M. V. Kremkov. **19**(8), 1103–4 (Feb. 1975); CPM-7504X1527

Kremnev, V. V.—Electron energy spectrum in high-energy nanosecond accelerators —V. V. Kremnev, G. A. Mesyats, and V. P. Reznikov. **19**(10), 1342–4 (Apr. 1975); CPM-7506X0276

Krivitskii, E. V.—Approximate similarity relations in the electrical explosions of underwater conductors —E. V. Krivitskii and V. K. Sholom. **19**(6), 798–801 (Dec. 1974); CPM-7501X0798

—Electrical characteristics of underwater exploding wires —V. K. Sholom, E. V. Krivitskii, and V. P. Litvinenko. **19**(10), 1329–31 (Apr. 1975); CPM-7506X0263

Krivorukov, E. V.—Modulation of microwaves by density fluctuations in a plasma —L. A. Dushin, A. V. Serikov, A. I. Skibenko, E. V. Krivorukov, and I. P. Fomin. **19**(9), 1163–7 (Mar. 1975); CPM-7505X0585

Krivulya, S. S.—Interaction of a hollow electron beam with a plasma —N. M. Zemlyanskii, A. K. Berezin, Ya. B. Fainberg, L. I. Bolotin, and S. S. Krivulya. **19**(12), 1547–8 (Jun. 1975); CPM-7508X0421

Krokhina, O. N.—NÉM-1T magnetic–discharge pumps in the vacuum system of the 1–100 linear accelerator —O. N. Krokhina and K. G. Mirzoev. **19**(5), 698–9 (Nov. 1974); CPM-7501X0492

Krupnik, L. I.—Conversion of neutral hydrogen into protons in dense plasmas —T. A. Bazilevskaya, L. I. Krupnik, and N. G. Shulika. **19**(6), 741–4 (Dec. 1974); CPM-7501X0741

—High-frequency modulation of atomic beams for plasma diagnostics —P. A. Demchenko, L. I. Krupnik, K. A. Leontovich, and E. S. Lyangner. **19**(10), 1362–6 (Apr. 1975); CPM-7506X0296

—Free expansion of plasma jets —P. A. Demchenko, L. I. Krupnik, and E. S. Lyangner. **19**(11), 1426–8 (May 1975); CPM-7506X1180

Kryzhanovskii, V. I.—Interaction of intense laser radiation with solid targets —L. V. Dubovoi, V. D. Dyatlov, V. I. Kryzhanovskii, A. A. Mak, R. N. Medvedev, A. N. Popytaev, V. A. Serebryakov, V. N. Sizov, and A. D. Starikov. **19**(11), 1477–9 (May 1975); CPM-7506X1231

Kudlai, V. A.—Cell for forming electron beams of arbitrary shape in a high-voltage gaseous discharge —I. V. Vagner, É. I. Bolgov, V. F. Grakun, V. L. Gokhfel'd, and V. A. Kudlai. **19**(8), 1042–5 (Feb. 1975); CPM-7504X1466

Kuklin, V. M.—Second–harmonic generation and emission in wave conversion at a plasma boundary —A. N. Kondratenko, V. G. Shaptala, and V. M. Kuklin. **19**(1), 22–4 (Jul. 1974); CPM-7407X1534

—Conversion of an electromagnetic wave into an ion–acoustic wave in an inhomogeneous plasma —A. N. Kondratenko and V. M. Kuklin. **19**(1), 25–7 (Jul. 1974); CPM-7407X1537

—Damping of ion–acoustic waves in a bounded plasma —A. N. Kondratenko and V. M. Kuklin. **19**(3), 326–8 (Sep. 1974); CPM-7412X1012

Kukushkin, A. S.—Long-wave cyclotron instability in a plasma in an inhomogeneous magnetic field —A. S. Kukushkin. **19**(3), 410–1 (Sep. 1974); CPM-7412X1096

Kuleshov, P. P.—Measurement of transverse relaxation time T_2 of optically oriented He^4 with an oscillator magnetometer —N. A. Dovator, R. A. Zhitnikov, and P. P. Kuleshov. **19**(12), 1608–9 (Jun. 1975); CPM-7508X0482

Kuleshov, V. M.—Switching characteristis of a discharge in water —V. M. Kuleshov, S. L. Nedoseev, V. P. Smirnov, and A. M. Spektor. **19**(1), 150–1 (Jul. 1974); CPM-7407X1662

Kulikov, Yu. A.—Secondary-electron energy in a resonance discharge in a three-electrode system —Yu. A. Kulikov, V. V. Ogienko, and Yu. M. Trifonov. **19**(8), 1090–2 (Feb. 1975); CPM-7504X1514

Kulish, A. F.—Exact solutions of the nonlinear electrodynamic equations —N. G. Puchkova and A. F. Kulish. **19**(12), 1614–5 (Jun. 1975); CPM-7508X0488

Kupryazhkin, A. Ya.—Diffusion and solubility of helium in potassium chloride —A. Ya. Kupryazhkin, P. V. Volobuev, and P. E. Suetin. **19**(8), 1105–7 (Feb. 1975); CPM-7504X1529

Kurbatov, Yu. A.—Energy input in electrical ionization lasers —Yu. I. Bychkov, Yu. D. Korolev, Yu. A. Kurbatov, and G. A. Mesyats. **19**(4), 499–502 (Oct. 1974); CPM-7412X0283

—Characteristics of the electrical ionization CO$_2$ laser —Yu. I. Bychkov, Yu. A. Kurbatov, and V. V. Savin. **19**(4), 506–8 (Oct. 1974); CPM-7412X0290

Kurdyumov, A. A.—Effect of the adsorption rate on the diffusion of deuterium through nickel —Yu. I. Belyakov, Yu. I. Zvezdin, A. A. Kurdyumov, and G. G. Nevdakha. **19**(7), 956–8 (Jan. 1975); CPM-7503X0844

Kurilko, V. I.—Cerenkov instabilities of a relativistic beam in a periodic plasma–filled waveguide —V. I. Kurilko, Yu. V. Tkach, and V. A. Shendrik. **19**(5), 607–11 (Nov. 1974); CPM-7501X0401

—Launching and propagation of regular nonlinear waves in an anisotropic plasma–filled waveguide —V. I. Kurilko, A. P. Tols–toluzhskii, and Ya. B. Fainberg. **19**(5), 622–7 (Nov. 1974); CPM-7501X0416

—Solitary waves in anisotropic plasma waveguide —V. I. Kurilko and A. P. Tolstoluzhskii. **19**(7), 887–90 (Jan. 1975); CPM-7503X0775

—Spectral narrowing of a single-mode beam oscillator —V. A. Buts and V. I. Kurilko. **19**(11), 1494–5 (May 1975); CPM-7506X1248

Kurnaev, V. A.—Energy spectra of scattered particles in proton bombardment of a metal target —G. I. Zhabrev, V. A. Kurnaev, and V. G. Tel'kovskii. **19**(7), 978–9 (Jan. 1975); CPM-7503X0866

Kursanov, Yu. V.—Low pressure discharge with high–energy electrons —R. A. Demirkhanov, Yu. V. Kursanov, and L. P. Skripal'. **19**(7), 891–4 (Jan. 1975); CPM-7503X0779

Kuts, P. S.—Dynamic magnetic–resonance phenomena —P. S. Kuts and V. S. Mel'nik. **19**(1), 110–4 (Jul. 1974); CPM-7407X1622

Kuz'min, R. N.—Contribution of multiphoton processes to the linear dielectric constant —V. A. Bushuev and R. N. Kuz'min. **19**(1), 116 (Jul. 1974); CPM-7407X1628

—Coherent Compton effect in crystals —V. A. Bushuev and R. N. Kuz'min. **19**(12), 1590–2 (Jun. 1975); CPM-7508X0464

Kuznetskii, R. S.—Effect of temperature-dependent conductivity on electromagnetic field, current, temperature, and impedance in a plane conductor. I —R. S. Kuznetskii. **19**(8), 1016–9 (Feb. 1975); CPM-7504X1440

Kuznetsov, V. S.—Beam focusing in an accelerator with inductive energy storage —V. A. Glukhikh, O. A. Gusev, E. G. Komar, V. S. Kuznetsov, M. P. Svin'in, and R. P. Fidel'skaya. **19**(3), 366–7 (Sep. 1974); CPM-7412X1052

—High–current pulsed electron accelerator with an annular beam —M. I. Avramenko, V. A. Glukhikh, O. A. Gusev, E. G. Komar, O. L. Komarov, V. S. Kuznetsov, A. S. Perlin, and M. P. Svin'in. **19**(3), 368–70 (Sep. 1974); CPM-7412X1054

—Maximum current of a beam with finite phase volume —G. I. Trubnikov and V. S. Kuznetsov. **19**(6), 715–6 (Dec. 1974); CPM-7501X0715

—Estimate of the angular divergence in intense electron beams —V. S. Kuznetsov, Yu. P. Vakhrushin, O. L. Komarov, and R. P. Fidel'skaya. **19**(7), 868–70 (Jan. 1975); CPM-7503X0756

Kuznetsov, Yu. D.—Charge–carrier density of the plasma produced in a Penning mixture by irradiation by uranium fission fragments and reactor radiation —G. A. Batyrbekov, Yu. D. Kuznetsov, and Zh. S. Takibaev. **19**(5), 645–6 (Nov. 1974); CPM-7501X0439

Kuznetsov, Yu. K.—Hydrodynamic stability of the Uragan stellarator —V. M. Zalkind, Yu. K. Kuznetsov, V. K. Pashnev, and V. M. Tonkopryad. **19**(8), 1123–5 (Feb. 1975); CPM-7504X1547

Kuzovkova, T. A.—Pulsed neodymium–glass laser with periodic Q switching —T. A. Kuzovkova, E. V. Nilov, V. A. Rusov, I. N. Semenov, and A. A. Chertkov. 19(4), 503–5 (Oct. 1974); CPM-7412X0287

Kuzovlev, V. F.—Ion-optical system for shaping high-current ion beams —S. D. Grishin, V. F. Kuzovlev, R. V. Orlov, and S. N. Ogorodnikov. 19(11), 1462–4 (May 1975); CPM-7506X1216

Kvochka, V. I.—Extraction of synchroton radiation from a cyclic electron accelerator with a strong magnetic field —V. I. Kvochka, V. S. Panasyuk, V. F. Romanovskii, L. N. Samoilov, A. A. Sokolov, B. M. Stepanov, and Yu. M. Tereshkin. 19(6), 762–6 (Dec. 1974); CPM-7501X0762

L

Laptev, I. D.—Neutral particles from the interaction of laser radiation with a solid target —Yu. A. Bykovskii, N. M. Vasil'ev, I. D. Laptev, and V. N. Nevolin. 19(12), 1635 (Jun. 1975); CPM-7508X0509

Lapteva, N. V.—Correlation analysis of fine-structure images —A. A. Kolesnikov and N. V. Lapteva. 19(9), 1181–4 (Mar. 1975); CPM-7505X0603

Larionov, M. M.—Role of collisions in plasma absorption of electromagnetic waves near the lower hybrid —B. V. Galaktionov, V. V. D'yachenko, M. M. Larionov, and O. N. Shcherbinin. 19(4), 459–62 (Oct. 1974); CPM-7412X0243

Latush, E. L.—Effect of the radiation density on ion drift velocity in a cadmium-helium laser —G. N. Tolmachev, E. L. Latush, and V. S. Mikhalevskii. 19(8), 1120–1 (Feb. 1975); CPM-7504X1544

Latypov, Z. Z.—Scattering of He$^+$ ions by the core of the He atom —Z. Z. Latypov and A. A. Shaporenko. 19(7), 976–7 (Jan. 1975); CPM-7503X0864

Lavrov, B. P.—Electron energy distribution in a constricted, low-pressure hydrogen discharge —M. A. Abroyan, Yu. M. Kagan, N. B. Kolokolov, and B. P. Lavrov. 19(11), 1492–3 (May 1975); CPM-7506X1246

Lazurik-Él'tsufin, V. T.—Excitation of thermoelastic vibrations of a thin plate by a beam of fast charged particles —A. I. Kalinichenko and V. T. Lazurik-Él'tsufin. 19(10), 1382–3 (Apr. 1975); CPM-7506X0316

Lebedev, A. N.—Magnetic-field transport of a high-current electron beam —A. V. Agafonov, V. S. Voronin, A. N. Lebedev, and K. N. Pazin. 19(9), 1188–92 (Mar. 1975); CPM-7505X0610

Lebedev, S. V.—Elimination of spherical aberration in an axial plasma lens —S. V. Lebedev and A. I. Morozov. 19(7), 966 (Jan. 1975); CPM-7503X0854

—Achromatic plasma–lens system —A. I. Morozov and S. V. Lebedev. 19(7), 967 (Jan. 1975); CPM-7503X0855

—Multiple–aperture ion source for electromagnetic mass separator —S. V. Lebedev. 19(7), 968 (Jan. 1975); CPM-7503X0856

—Design of axisymmetric plasma lenses —A. I. Morozov and S. V. Lebedev. 19(8), 996–1000 (Feb. 1975); CPM-7504X1420

Lebedev, S. Ya.—Extrapolation of the Langmuir S–curve to cesium pressures of 10–100 torr —V. E. Dubinskii and S. Ya. Lebedev. 19(1), 81–3 (Jul. 1974); CPM-7407X1593

Lebedev, V. V.—Mass spectrum of secondary ions ejected from the surface of a single crystal of gallium arsenide by argon ions —A. G. Koval', V. V. Bobkov, Yu. A. Klimovskii, S. S. Strel'chenko, V. V. Shubina, V. V. Lebedev, and Ya. M. Fogel'. 19(12), 1587–9 (Jun. 1975); CPM-7508X0461

Lentsman, V. L.—Electron–scanning transformation of the potential distribution on an electrostatic target —V. L. Lentsman. 19(5), 678–9 (Nov. 1974); CPM-7501X0472

Leonov, R. K.—Nonradiative electron transitions and thermal effects in laser–irradiated transparent dielectrics —B. I. Makshantsev, A. A. Kovalev, R. K. Leonov, and P. A. Yampol'skii. 19(1), 98–102 (Jul. 1974); CPM-7407X1610

Leontovich, K. A.—High-frequency modulation of atomic beams for plasma diagnostics —P. A. Demchenko, L. I. Krupnik, K. A. Leontovich, and E. S. Lyangner. 19(10), 1362–6 (Apr. 1975); CPM-7506X0296

Leskov, L. V.—Effect of a high-current relativistic electron beam on a metal —B. I. Dmitrenko, L. V. Leskov, G. P. Maksimov, S. L. Nedoseev, V. V. Savichev, V. P. Smirnov, and A. M. Spektor. 19(9), 1224–5 (Mar. 1975); CPM-7505X0646

—Formation of a plasma focus in a plasma erosion accelerator. II. Energy characteristics of the dense plasma focus —N. P. Kozlov, L. V. Leskov, Yu. S. Protasov, and V. I. Khvesyuk. 19(12), 1558–9 (Jun. 1975); CPM-7508X0432

Levin, M. L.—Potential factors for an inhomogeneous ellipsoid —M. L. Levin and R. Z. Muratov. 19(2), 169–70 (Aug. 1974); CPM-7408X1433

Levin, V. M.—Linear accelerator for beam injection into a slowly rising magnetic field —D. G. Borisov, A. I. Gryzlov, V. M. Levin, and A. V. Ryabtsov. 19(4), 509–10 (Oct. 1974); CPM-7412X0293

Levitan, M. M.—Fundamentals of heat-pipe theory and design —M. M. Levitan and T. L. Perel'man. 19(8), 983–95 (Feb. 1975); CPM-7504X1407

Lin'kov, R. V.—Ponderomotive forces on a rotating conducting sphere in a time-varying inhomogeneous magnetic field —R. V. Lin'kov and Yu. M. Urman. 19(11), 1393–8 (May 1975); CPM-7506X1147

Listovets, V. S.—Hologram interferometry for vibration analysis —V. S. Listovets and Yu. I. Ostrovskii. 19(7), 847–60 (Jan. 1975); CPM-7503X0735

Litunovskii, V. N.—Coaxial plasma injector with programmed injection —V. A. Burtsev, V. N. Litunovskii, and M. P. Nadgornaya. 19(6), 736–40 (Dec. 1974); CPM-7501X0736

Litvinenko, V. P.—Electrical characteristics of underwater exploding wires —V. K. Sholom, E. V. Krivitskii, and V. P. Litvinenko. 19(10), 1329–31 (Apr. 1975); CPM-7506X0263

Litvinov, E. A.—Perveance of a vacuum with a point cathode —S. P. Bugaev, E. A. Litvinov, V. V. Lopatin, and G. A. Mesyats. 19(1), 88–90 (Jul. 1974); CPM-7407X1600

—Transient thermionic-field emission from a point cathode —E. A. Litvinov and A. F. Shubin. 19(8), 1131–2 (Feb. 1975); CPM-7504X1555

Livadonov, V. Sh.—Nonlinear plasma waves and ion–acoustic waves in an isotropic plasma —V. Sh. Livadonov and S. M. Fainshtein. 19(1), 28–30 (Jul. 1974); CPM-7407X1540

Loiko, A. É.—Temperature dependence of trace diffusion coefficients of certain gases —A. É. Loiko, B. A. Ivakin, and P. E. Suetin. 19(3), 434 (Sep. 1974); CPM-7412X1120

Loiko, T. V.—Fast electrons and x rays from nanosecond gas discharges at 0.1–760 torr —L. V. Tarasova, L. N. Khudyakova, T. V. Loiko, and V. A. Tsukerman. 19(3), 351–3 (Sep. 1974); CPM-7412X1037

Lominadze, D. G.—Excitation of electromagnetic ion cyclotron waves by fast ions —T. D. Kaladze, D. G. Lominadze, and K. N. Stepanov. 19(2), 175–6 (Aug. 1974); CPM-7408X1439

—Transverse-current plasma instability —D. G. Lominadze and V. L. Sizonenko. 19(9), 1145–9 (Mar. 1975); CPM-7505X0567

—Plasma instability due to an anisotropic electron distribution —D. G. Lominadze and V. L. Sizonenko. 19(9), 1150–3 (Mar. 1975); CPM-7505X0572

Lomino, N. S.—Focusing of a neutralized ion beam by a plasma–optics system —I. I. Demidenko, N. S. Lomino, A. I. Morozov, and V. G. Padalka. 19(3), 347–50 (Sep. 1974); CPM-7412X1033

—Effect of rf ionization on Hall-current plasma accelerator —I. I. Demidenko, N. S. Lomino, A. I. Morozov, and V. G. Padalka. 19(12), 1560–3 (Jun. 1975); CPM-7508X0434

Lonin, Yu. F.—Plasma equilibrium and confinement in a poloidal heliotron configuration. I —V. G. Zykov, V. I. Karpukhin, Yu. F. Lonin, N. N. Podteregera, N. I. Rudnev, and V. T. Tolok. 19(8), 1063–8 (Feb. 1975); CPM-7504X1487

—Plasma equilibrium and confinement in a poloidal heliotron configuration. II —V. G. Zykov, V. I. Karpukhin, Yu. F. Lonin, N. N. Podteregera, N. I. Rudnev, A. Y. Skibenko, V. T. Tolok, and I. P. Fomin. 19(8), 1069–72 (Feb. 1975); CPM-7504X1493

Lopatin, V. V.—Perveance of a vacuum with a point cathode —S. P. Bugaev, E. A. Litvinov, V. V. Lopatin, and G. A. Mesyats. 19(1), 88–90 (Jul. 1974); CPM-7407X1600

Lopushanskaya, A. I.—A useful function in the thermodynamics of irreversible processes —A. V. Pamfilov, A. I. Lopushanskaya, and L. B. Tsvetkova. 19(4), 535–7 (Oct. 1974); CPM-7412X0319

—Local–potential study of the Bénard problem in a homogeneous magnetic field —A. I. Lopushanskaya and V. N. Kapranov. 19(5), 612–4 (Nov. 1974); CPM-7501X0406

Loshkarev, A. I.—Nonmonotonic potential distribution in the electrode region —A. I. Loshkarev. 19(10), 1308–11 (Apr. 1975); CPM-7506X0242

—Analytic model for the arc regime and the thermionic converter —V. D. Bondarenko and A. I. Loshkarev. 19(12), 1564–8 (Jun. 1975); CPM-7508X0438

Lovetskii, E. E.—Recombination in an expanding plasma —Yu. A. Bykovskii, N. N. Degtyarenko, V. F. Elesin, V. E. Kondrashov, E. E. Lovetskii, A. N. Polyanichev, and V. S. Fetisov. 19(1), 43–8 (Jul. 1974); CPM-7407X1555
—Surface waves in a magnetized plasma in a radio-frequency field —E. E. Lovetskii and A. N. Starodub. 19(3), 319–22 (Sep. 1974); CPM-7412X1005
—Expansion of a recombining plasma in vacuum —E. E. Lovetskii, A. N. Polyanichev, and V. S. Fetisov. 19(5), 647–50 (Nov. 1974); CPM-7501X0441
Lozanskii, É. D.—Effects due to streamer shape —É. D. Lozanskii and D. B. Pontekorvo. 19(11), 1432–3 (May 1975); CPM-7506X1186
Lozovich, M. R.—Physical properties of an electrodeless pulsed discharge in a gas-filled glass cell —Yu. I. Chutov, N. S. Baranchuk, M. R. Lozovich, and V. G. Danilov. 19(2), 224–8 (Aug. 1974); CPM-7408X1488
Lubinskii, S. I.—Direct current in a metal—selenium—metal structure boundary by an rf plasma —A. D. Andreev and S. I. Lubinskii. 19(12), 1606–7 (Jun. 1975); CPM-7508X0480
Lukin, A. N.—Resistance and inductance of a gas arc —S. I. Barannik, S. B. Vasserman, and A. N. Lukin. 19(11), 1449–53 (May 1975); CPM-7506X1203
Luknitskii, V. A.—Evaporation rates of the system $ZrC+x\%W$ for the temperature range 2300-3000°K —N. M. Karnaukhova, V. A. Luknitskii, and I. A. Maslov. 19(8), 1096–9 (Feb. 1975); CPM-7504X1520
Luk'yanchikov, G. S.—Multiphase, uniform, secondary-emission microwave discharge at a solid surface —G. S. Luk'yanchikov. 19 (9), 1196–9 (Mar. 1975); CPM-7505X0618
Lun'kin, Yu. P.—Lagrange problem in magnetohydrodynamics —P. V. Zagorskii and Yu. P. Lun'kin. 19(8), 1009–11 (Feb. 1975); CPM-7504X1433
L'vov, B. V.—Effect of a magnetic field on spontaneous mode-locking in a He—Ne laser $(\Lambda=0.63\mu)$ —V. Yu. Petrun'kin, V. M. Nikolaev, O. I. Kotov, and B. V. L'vov. 19(12), 1612–3 (Jun. 1975); CPM-7508X0486
Lyagushchenko, R. I.—Electron energy distribution in the afterglow. I —A. B. Blagoev, Yu. M. Kagan, N. B. Kolokolov, and R. I. Lyagushchenko. 19(2), 211–4 (Aug. 1974); CPM-7408X1475
—Electron energy distribution in the afterglow. II —A. B. Blagoev, Yu. M. Kagan, N. B. Kolokolov, and R. I. Lyagushchenko. 19(2), 215–9 (Aug. 1974); CPM-7408X1479
—Theory of the positive column in neon —Yu. B. Golobovskii, Yu. M. Kagan, and R. I. Lyagushchenko. 19(3), 335–9 (Sep. 1974); CPM-7412X1021
—Electron density in an argon afterglow —O. P. Bochkova, R. I. Lyagushchenko, É. A. Sukiasyan, and Yu. A. Tolmachev. 19(4), 475–7 (Oct. 1974); CPM-7412X0259
Lyangner, E. S.—High-frequency modulation of atomic beams for plasma diagnostics —P. A. Demchenko, L. I. Krupnik, K. A. Leontovich, and E. S. Lyangner. 19(10), 1362–6 (Apr. 1975); CPM-7506X0296
—Free expansion of plasma jets —P. A. Demchenko, L. I. Krupnik, and E. S. Lyangner. 19(11), 1426–8 (May 1975); CPM-7506X1180
Lyapin, A. A.—Microcells in cold cathodes —N. P. Kozlov, A. A. Lyapin, and V. I. Khvesyuk. 19(8), 1093–5 (Feb. 1975); CPM-7504X1517
Lyapin, A. G.—Hydrogen-ion mobility in a high-pressure unipolar corona —A. G. Lyapin. 19(9), 1236–8 (Mar. 1975); CPM-7505X0658
Lytkin, V. V.—Investigation of the work function of a tungsten cathode after bombardment by inert-gas ions —P. N. Chistyakov, R. A. Milovanova, and V. V. Lytkin. 19(1), 148–9 (Jul. 1974); CPM-7407X1660
Lyubashevskaya, T. L.—Dependence of the basic parameters of $Al_xGa_{1-x}As$—GaAs solar converters on temperature and optical intensity —E. B. Vinogradova, M. B. Kagan, N. S. Koroleva, T. L. Lyubashevskaya, and T. A. Nuller. 19(10), 1378–81 (Apr. 1975); CPM-7506X0312
Lyubchik, Ya. G.—Fifth-order spherical aberration in focusing and correcting quadrupole—octupole systems —Ya. G. Lyubchik and T. Ya. Fishkova. 19(11), 1403–7 (May 1975); CPM-7506X1157
Lyubin, V. M.—Reversibility of chalcogenide materials in holography —S. B. Gurevich, N. N. Il'yashenko, B. T. Kolomiets, V. M. Lyubin, and M. V. Sukharev. 19(1), 152–3 (Jul. 1974); CPM-7407X1664
Lyubitov, Yu. N.—Transient molecular effusion characteristics —Yu. N. Lyubitov and V. Z. Belen'kii. 19(4), 519–22 (Oct. 1974); CPM-7412X0303
—Composition of adsorbing and desorbing fluxes —Yu. A. Gel'man, V. I. Mikhailov, V. F. Vinogradov, and Yu. N. Lyubitov. 19(10), 1355–8 (Apr. 1975); CPM-7506X0289
Lyutomskii, V. A.—Experimental investigation of microwave radiation produced by hypersonic flows —V. A. Lyutomskii, V. M. Polyakov, and V. G. Testov. 19(4), 483–5 (Oct. 1974); CPM-7412X0267

M

Maergoiz, I. D.—Rectangular conducting wedge in a moving electromagnetic field —I. D. Maergoiz and L. P. Nizhnik. 19(10), 1281–6 (Apr. 1975); CPM-7506X0215
Magda, I. I.—Transmission of a high-current relativistic beam through a gas —Yu. V. Tkach, I. I. Magda, G. V. Skachek, S. S. Pushkarev, and I. P. Panchenko. 19(3), 412–3 (Sep. 1974); CPM-7412X1098
—Self-acceleration of an intense electron beam —I. A. Grishaev, A. N. Dedik, V. V. Zakutin, I. I. Magda, Yu. V. Tkach, and A. M. Shenderovich. 19(8), 1087–9 (Feb. 1975); CPM-7504X1511
Mak, A. A.—Parasitic amplitude modulation of a stabilized Nd^{3+}:YAG laser —N. M. Galaktionova, A. A. Mak, and A. P. Khyuppenen. 19(4), 486–90 (Oct. 1974); CPM-7412X0270
—Unidirectional cw oscillation in a solid state ring laser with a return mirror —A. A. Mak, V. I. Ustyugov, V. A. Fromzel', and M. M. Khaleev. 19(4), 552–3 (Oct. 1974); CPM-7412X0336
—Lasing properties of Yb^{3+} and Er^{3+} glass laser pumped by a laser —V. N. Kalinin, A. A. Mak, D. S. Prilezhaev, and V. A. Fromzel'. 19(6), 835–6 (Dec. 1974); CPM-7501X0835
—Solid-state laser with externally forced *Q* switching —N. M. Galaktionova, A. A. Mak, and A. P. Khyuppenen. 19(9), 1174–6 (Mar. 1975); CPM-7505X0596
—Interaction of intense laser radiation with solid targets —L. V. Dubovoi, V. D. Dyatlov, V. I. Kryzhanovskii, A. A. Mak, R. N. Medvedev, A. N. Popytaev, V. A. Serebryakov, V. N. Sizov, and A. D. Starikov. 19(11), 1477–9 (May 1975); CPM-7506X1231
Makarevich, A. A.—Laser-initiated vacuum discharge —V. P. Kovalenko, A. A. Makarevich, V. A. Rodichkin, and A. M. Timonin. 19(11), 1429–31 (May 1975); CPM-7506X1183
Makarov, G. I.—Reflecting properties of an inhomogeneous anisotropic plasma layer —V. A. Zhivulin and G. I. Makarov. 19 (1), 123 (Jul. 1974); CPM-7407X1635
Makhan'kov, V. G.—Excitation of acoustic waves by ion-acoustic turbulence —Kh. O. Abdulloev, F. Kh. Khakimov, and V. G. Makhan'kov. 19(4), 441–5 (Oct. 1974); CPM-7412X0225
Makshantsev, B. I.—Nonradiative electron transitions and thermal effects in laser-irradiated transparent dielectrics —B. I. Makshantsev, A. A. Kovalev, R. K. Leonov, and P. A. Yampol'skii. 19(1), 98–102 (Jul. 1974); CPM-7407X1610
—Surface evaporation of a solid transparent dielectric under the action of laser radiation —A. M. Bonch-Bruevich, Ya. A. Imas, A. A. Kovalev, P. S. Kondratenko, and B. I. Makshantsev. 19(11), 1474–6 (May 1975); CPM-7506X1228
Maksimov, A. I.—Electron energy distribution and electrical characteristics of the positive column in H_2 and H_2+Cl_2 —V. V. Zaitsev, A. I. Maksimov, and V. I. Svettsov. 19(1), 57–9 (Jul. 1974); CPM-7407X1569
—Radial distribution of density and potential in a glow discharge in CO_2 and water —A. I. Maksimov and V. F. Sokolov. 19(10), 1359–61 (Apr. 1975); CPM-7506X0293
Maksimov, G. P.—Effect of a high-current relativistic electron beam on a metal —B. I. Dmitrenko, L. V. Leskov, G. P. Maksimov, S. L. Nedoseev, V. V. Savichev, V. P. Smirnov, and A. M. Spektor. 19(9), 1224–5 (Mar. 1975); CPM-7505X0646
Maksimov, V. G.—Simplified model for the initial stage of exploding wire phenomena —N. N. Stolovich, V. G. Maksimov, and N. S. Minitskaya. 19(10), 1321–8 (Apr. 1975); CPM-7506X0255
Malyavin, L. A.—Electric field and plasma structure near a large charged body —L. A. Malyavin and A. M. Moskalenko. 19(2), 197–200 (Aug. 1974); CPM-7408X1461
—Structure of a perturbation near a highly charged body in a weakly ionized plasma —L. A. Malyavin and A. M. Moskalenko. 19(2), 206–10 (Aug. 1974); CPM-7408X1470

Malyshev, G. M.—Diagnostics of a laser-produced plasma by a scattering method using an electron-optical image converter —E. A. Burunov, G. M. Malyshev, G. T. Razdobarin, and V. V. Semenov. 19(1), 66–9 (Jul. 1974); CPM-7407X1578

Malyugin, V. I.—Evaluation of charge distribution in a crossed-field device from ion bombardment of the cathode —V. I. Malyugin and G. G. Sominskii. 19(7), 942–5 (Jan. 1975); CPM-7503X0830

Mandrusov, V. E.—Dielectric properties of foamed ceramics at millimeter wavelengths —N. A. Irisova, G. V. Kozlov, V. E. Mandrusov, B. S. Cherepanov, and I. M. Chernyshev. 19(1), 103–4 (Jul. 1974); CPM-7407X1615

Mantrova, G. M.—Electromagnetic fields outside a synthesized plasma jet —E. V. Bogdanov, G. M. Mantrova, and M. N. Yakovleva. 19(7), 919–21 (Jan. 1975); CPM-7503X0807

Marasin, L. E.—Time characteristics of the near radiation field of the injection laser —Zh. I. Alferov, V. N. Deryagin, L. E. Marasin, Yu. V. Popov, and E. L. Portnoi. 19(4), 548 (Oct. 1974); CPM-7412X0332

Markeev, B. M.—Method for studying gas creep along a solid surface —B. M. Markeev. 19(5), 700–1 (Nov. 1974); CPM-7501X0494

—Viscous momentum transport in a gaseous mixture —B. M. Markeev. 19(7), 969–70 (Jan. 1975); CPM-7503X0857

—State of a gas moving near a solid surface —S. P. Bakanov and B. M. Markeev. 19(10), 1293–4 (Apr. 1975); CPM-7506X0227

Markov, V. B.—Shaping of voltage pulses by discharging an inductive storage bank with a charged-particle beam —O. A. Gusev, E. G. Komar, V. B. Markov, and E. M. Mellekh. 19(5), 662–3 (Nov. 1974); CPM-7501X0456

Marshak, I. S.—Radiating discharges confined by walls —A. F. Aleksandrov, I. S. Marshak, and A. A. Rukhadze. 19(3), 308–14 (Sep. 1974); CPM-7412X0994

Martynenko, V. V.—Anisotropic plasma heating near the lower hybrid frequency —V. M. Glagolev, V. V. Martynenko, and Yu. V. Skosyrev. 19(12), 1543–6 (Jun. 1975); CPM-7508X0417

Martynyuk, M. M.—Vaporization and boiling of liquid metal in an exploding wire —M. M. Martynyuk. 19(6), 793–7 (Dec. 1974); CPM-7501X0793

—Electrical explosion of the metastable liquid phases of zinc, cadmium, and lead —M. M. Martynyuk and I. Karimkhodzhaev. 19(11), 1454–7 (May 1975); CPM-7506X1208

—Resistance and enthalpy of refractory exploding wires —M. M. Martynyuk, I. Karimkhodzhaev, and V. I. Tsapkov. 19(11), 1458–61 (May 1975); CPM-7506X1212

Marugin, A. M.—Laser compensation for thermal distortion in optical pumping —V. K. Zaitsev, V. A. Il'inskii, A. M. Marugin, and V. M. Ovchinnikov. 19(11), 1480–1 (May 1975); CPM-7506X1234

Mashkova, E. S.—Energy dependence of the focusing of ions by crystals —E. S. Mashkova, V. A. Molchanov, and A. D. Pavlova. 19(4), 540 (Oct. 1974); CPM-7412X0324

Maslov, A. I.—Spatial characteristics and loss of plasma produced by an electron beam in a magnetic trap —M. Yu. Bredikhin, A. I. Maslov, A. I. Skibenko, E. I. Skibenko, I. P. Fomin, and V. B. Yuferov. 19(1), 49–52 (Jul. 1974); CPM-7407X1561

Maslov, I. A.—Evaporation rates of the system ZrC+x%W for the temperature range 2300-3000°K —N. M. Karnaukhova, V. A. Luknitskii, and I. A. Maslov. 19(8), 1096–9 (Feb. 1975); CPM-7504X1520

Masunov, E. S.—Coherent instability of a beam in a vacuum chamber with an irregular boundary —E. S. Masunov. 19(9), 1185–7 (Mar. 1975); CPM-7505X0607

Medvedev, R. N.—Interaction of intense laser radiation with solid targets —L. V. Dubovoi, V. D. Dyatlov, V. I. Kryzhanovskii, A. A. Mak, R. N. Medvedev, A. N. Popytaev, V. A. Serebryakov, V. N. Sizov, and A. D. Starikov. 19(11), 1477–9 (May 1975); CPM-7506X1231

Medvedev, Yu. A.—Electron lifetimes in atmosphere at high pressure —V. N. Kapinos, Yu. A. Medvedev, N. N. Morozov, and B. M. Stepanov. 19(11), 1507 (May 1975); CPM-7506X1261

Meilikhov, E. Z.—Current-convective instability in a three-component plasma —E. Z. Meilikhov. 19(12), 1610–1 (Jun. 1975); CPM-7508X0484

Melikov, I. V.—Experimental investigation of anode processes in a closed electron-drift accelerator —I. V. Melikov. 19(1), 35–7 (Jul. 1974); CPM-7407X1547

—Similitude in Hall-current plasma accelerators —A. I. Morozov and I. V. Melikov. 19(3), 340–2 (Sep. 1974); CPM-7412X1026

—Equilibrium flow in a Hall-current plasma accelerator —I. V. Melikov. 19(3), 343–6 (Sep. 1974); CPM-7412X1029

Mellekh, E. M.—Shaping of voltage pulses by discharging an inductive storage bank with a charged-particle beam —O. A. Gusev, E. G. Komar, V. B. Markov, and E. M. Mellekh. 19(5), 662–3 (Nov. 1974); CPM-7501X0456

Mel'nik, V. S.—Dynamic magnetic-resonance phenomena —P. S. Kuts and V. S. Mel'nik. 19(1), 110–4 (Jul. 1974); CPM-7407X1622

Mel'nikov, M. A.—Dielectric breakdown of detonation products —V. L. Korol'kov, M. A. Mel'nikov, and A. P. Tsyplenko. 19(12), 1569–70 (Jun. 1975); CPM-7508X0443

Meriakri, V. V.—Dispersion of the dielectric constant of crystalline KH_2PO_4 near the "soft" mode frequency —V. V. Meriakri, Yu. M. Poplavko, and E. F. Ushatkin. 19(5), 703–4 (Nov. 1974); CPM-7501X0497

Merker, É. A.—Proton extraction from the 70-GeV accelerator for the Ludmila liquid-hydrogen chamber (extraction system S) —A. A. Aseev, A. I. Drozhdin, B. A. Zelenov, É. A. Merker, L. L. Moizhes, K. P. Myznikov, A. A. Roshchin, V. M. Tatarenko, M. A. Kholodenko, A. D. Artemov, L. N. Vaulin, V. I. Gordin, I. I. Kovalevskii, V. N. Rozhkov, M. M. Suvorov, A. S. Sudarushkin, and V. I. Chuiko. 19(1), 70–6 (Jul. 1974); CPM-7407X1582

Meshcheryakov, S. A.—Two modes of operation of an arc plasma source in an external magnetic field —A. G. Korsun and S. A. Meshcheryakov. 19(11), 1500–1 (May 1975); CPM-7506X1254

Mesyats, G. A.—Perveance of a vacuum with a point cathode —S. P. Bugaev, E. A. Litvinov, V. V. Lopatin, and G. A. Mesyats. 19(1), 88–90 (Jul. 1974); CPM-7407X1600

—High-power nanosecond electron accelerator with inductive storage —B. M. Koval'chuk, Yu. A. Kotov, and G. A. Mesyats. 19(1), 136–7 (Jul. 1974); CPM-7407X1648

—Energy input in electrical ionization lasers —Yu. I. Bychkov, Yu. D. Korolev, Yu. A. Kurbatov, and G. A. Mesyats. 19(4), 499–502 (Oct. 1974); CPM-7412X0283

—Nanosecond x-ray pulses —G. A. Mesyats. 19(7), 948–51 (Jan. 1975); CPM-7503X0836

—Electron energy spectrum in high-energy nanosecond accelerators —V. V. Kremnev, G. A. Mesyats, and V. P. Reznikov. 19(10), 1342–4 (Apr. 1975); CPM-7506X0276

Metallov, O. A.—Ion focusing of an electron beam in deep melting of a metal —M. D. Gabovich, V. P. Kovalenko, O. A. Metallov, O. K. Nazarenko, and S. K. Pats'ora. 19(7), 973–4 (Jan. 1975); CPM-7503X0861

Mikhailov, V. I.—Composition of adsorbing and desorbing fluxes —Yu. A. Gel'man, V. I. Mikhailov, V. F. Vinogradov, and Yu. N. Lyubitov. 19(10), 1355–8 (Apr. 1975); CPM-7506X0289

Mikhalev, L. A.—Contraction of the positive column of a glow discharge due to the presence of negative ions —L. A. Mikhalev and L. N. Selin. 19(5), 689–90 (Nov. 1974); CPM-7501X0483

Mikhalevskii, V. S.—Effect of the radiation density on ion drift velocity in a cadmium-helium laser —G. N. Tolmachev, E. L. Latush, and V. S. Mikhalevskii. 19(8), 1120–1 (Feb. 1975); CPM-7504X1544

Milenin, V. M.—Effect of cathode emission on the threshold for striations —N. A. Vorob'eva, Yu. M. Kagan, V. M. Milenin, and A. Kh. Muradov. 19(1), 117–8 (Jul. 1974); CPM-7407X1629

Milovanov, O. S.—Multiple-section linear electron accelerator with synchronized oscillators —V. F. Vikulov, V. A. Volodin, and O. S. Milovanov. 19(7), 930–1 (Jan. 1975); CPM-7503X0818

Milovanova, R. A.—Investigation of the work function of a tungsten cathode after bombardment by inert-gas ions —P. N. Chistyakov, R. A. Milovanova, and V. V. Lytkin. 19(1), 148–9 (Jul. 1974); CPM-7407X1660

Minitskaya, N. S.—Simplified model for the initial stage of exploding wire phenomena —N. N. Stolovich, V. G. Maksimov, and N. S. Minitskaya. 19(10), 1321–8 (Apr. 1975); CPM-7506X0255

Mironov, O. N.—Forces in a Hall plasma accelerator —O. N. Mironov. 19(3), 329–34 (Sep. 1974); CPM-7412X1015

Mironov, V. D.—Multiple reflection of light in a shock tube —V. D. Mironov and V. I. Selyakov. 19(3), 402–4 (Sep. 1974); CPM-7412X1088

Mironovich, V. L.—Analytic model of the cesium arc —V. P. Pashchenko, V. L. Mironovich, and I. P. Stakhanov. 19(10), 1332–6 (Apr. 1975); CPM-7506X0266

Miroshnichenko, V. I.—Reflection of electromagnetic waves by a moving plasma —V. I. Miroshnichenko. 19(4), 533–4 (Oct. 1974); CPM-7412X0317

Mirzoev, K. G.—Titanium–pump system for hydrogen —K. G. Mirzoev, V. G. Rogozinskii, and V. L. Ushkov. 19(3), 432–3 (Sep. 1974); CPM-7412X1118

—NÉM–1T magnetic–discharge pumps in the vacuum system of the 1–100 linear accelerator —O. N. Krokhina and K. G. Mirzoev. 19 (5), 698–9 (Nov. 1974); CPM-7501X0492

Mishin, G. I.—Statistical characteristics of the turbulent wake behind a supersonic sphere —V. G. Ivanov, G. I. Mishin, and S. N. Palkin. 19(4), 543–5 (Oct. 1974); CPM-7412X0327

Mitina, N. I.—Magnetic field in a θ pinch with an axial conductor —Ya. F. Volkov, V. G. Dyatlov, and N. I. Mitina. 19(3), 323–5 (Sep. 1974); CPM-7412X1009

—Optical investigation of a turbulent plasma —Ya. F. Volkov, V. G. Dyatlov, and N. I. Mitina. 19(7), 905–8 (Jan. 1975); CPM-7503X0793

Mittsev, M. A.—Adsorption of bismuth on tungsten. I. Steady–state processes —M. A. Mittsev. 19(6), 811–4 (Dec. 1974); CPM-7501X0811

Mizerov, M. N.—Characteristics of diffraction gratings obtained by photoetching of semiconductor surfaces —L. V. Belyakov, D. N. Goryachev, M. N. Mizerov, and E. L. Portnoi. 19(6), 837–8 (Dec. 1974); CPM-7501X0837

Mnatsakanyan, A. Kh.—Energy exchange between electrons and molecular vibrational states in resonance collisions —A. Kh. Mnatsakanyan and G. V. Naidis. 19(8), 1113–5 (Feb. 1975); CPM-7504X1537

Moiseev, S. S.—Transformation of nonlinear MHD waves —G. M. Zaslavskii, S. S. Moiseev, and V. V. Mukhin. 19(12), 1534–7 (Jun. 1975); CPM-7508X0408

Moizhes, B. Ya.—Anomalous high emission of a nonevaporating thermionic cathode in an arc —B. Ya. Moizhes and V. A. Nemchinskii. 19(12), 1571–6 (Jun. 1975); CPM-7508X0445

Moizhes, L. L.—Proton extraction from the 70–GeV accelerator for the Ludmila liquid–hydrogen chamber (extraction system S) —A. A. Aseev, A. I. Drozhdin, B. A. Zelenov, É. A. Merker, L. L. Moizhes, K. P. Myznikov, A. A. Roshchin, V. M. Tatarenko, M. A. Kholodenko, A. D. Artemov, L. N. Vaulin, V. I. Gordin, I. I. Kovalevskii, V. N. Rozhkov, M. M. Suvorov, A. S. Sudarushkin, and V. I. Chuiko. 19(1), 70–6 (Jul. 1974); CPM-7407X1582

Molchanov, V. A.—Effect of crystal structure on certain angular dependence of the ion–electron–emission yield —B. A. Brusilovskii and V. A. Molchanov. 19(1), 84–7 (Jul. 1974); CPM-7407X1596

—Energy dependence of the focusing of ions by crystals —E. S. Mashkova, V. A. Molchanov, and A. D. Pavlova. 19(4), 540 (Oct. 1974); CPM-7412X0324

Morgulis, N. D.—Effect of molecular hydrogen on a cesium discharge. I —N. D. Morgulis and V. I. Klapchenko. 19(7), 911–3 (Jan. 1975); CPM-7503X0799

Morozov, A. I.—Radiation energy of a magnetoplasma compressor —V. I. Berkov and A. I. Morozov. 19(2), 220–3 (Aug. 1974); CPM-7408X1484

—Similitude in Hall–current plasma accelerators —A. I. Morozov and I. V. Melikov. 19(3), 340–2 (Sep. 1974); CPM-7412X1026

—Focusing of a neutralized ion beam by a plasma–optics system —I. I. Demidenko, N. S. Lomino, A. I. Morozov, and V. G. Padalka. 19(3), 347–50 (Sep. 1974); CPM-7412X1033

—Plasma density in a magnetoplasma compressor —A. K. Vinogradova, V. P. Vinogradov, A. I. Morozov, and A. A. Sergeev. 19(3), 421–3 (Sep. 1974); CPM-7412X1107

—Elimination of spherical aberration in an axial plasma lens —S. V. Lebedev and A. I. Morozov. 19(7), 966 (Jan. 1975); CPM-7503X0854

—Achromatic plasma–lens system —A. I. Morozov and S. V. Lebedev. 19(7), 967 (Jan. 1975); CPM-7503X0855

—Design of axisymmetric plasma lenses —A. I. Morozov and S. V. Lebedev. 19(8), 996–1000 (Feb. 1975); CPM-7504X1420

—Effect of rf ionization on Hall–current plasma accelerator —I. I. Demidenko, N. S. Lomino, A. I. Morozov, and V. G. Padalka. 19 (12), 1560–3 (Jun. 1975); CPM-7508X0434

Morozov, N. N.—Electron lifetimes in atmosphere at high pressure —V. N. Kapinos, Yu. A. Medvedev, N. N. Morozov, and B. M. Stepanov. 19(11), 1507 (May 1975); CPM-7506X1261

Moskalenko, A. M.—Electric field and plasma structure near a large charged body —L. A. Malyavin and A. M. Moskalenko. 19(2), 197–200 (Aug. 1974); CPM-7408X1461

—Structure of a perturbation near a highly charged body in a weakly ionized plasma —L. A. Malyavin and A. M. Moskalenko. 19(2), 206–10 (Aug. 1974); CPM-7408X1470

Moskalev, I. N.—Measurement of plasma density distribution with a rectangular microwave cavity —I. N. Moskalev. 19(9), 1168–70 (Mar. 1975); CPM-7505X0590

Mozgin, V. V.—Elimination of carbon impurities from platinum by heating in an oxygen atmosphere —L. P. Rekova, V. V. Mozgin, L. N. Zvyagintseva, V. N. Bondarenko, and Ya. M. Fogel'. 19(11), 1465–7 (May 1975); CPM-7506X1219

Mukhin, V. V.—Transformation of nonlinear MHD waves —G. M. Zaslavskii, S. S. Moiseev, and V. V. Mukhin. 19(12), 1534–7 (Jun. 1975); CPM-7508X0408

Muradov, A. Kh.—Effect of cathode emission on the threshold for striations —N. A. Vorob'eva, Yu. M. Kagan, V. M. Milenin, and A. Kh. Muradov. 19(1), 117–8 (Jul. 1974); CPM-7407X1629

Muratov, R. Z.—Potential factors for an inhomogeneous ellipsoid —M. L. Levin and R. Z. Muratov. 19(2), 169–70 (Aug. 1974); CPM-7408X1433

Myznikov, K. P.—Proton extraction from the 70–GeV accelerator for the Ludmila liquid–hydrogen chamber (extraction system S) —A. A. Aseev, A. I. Drozhdin, B. A. Zelenov, É. A. Merker, L. L. Moizhes, K. P. Myznikov, A. A. Roshchin, V. M. Tatarenko, M. A. Kholodenko, A. D. Artemov, L. N. Vaulin, V. I. Gordin, I. I. Kovalevskii, V. N. Rozhkov, M. M. Suvorov, A. S. Sudarushkin, and V. I. Chuiko. 19(1), 70–6 (Jul. 1974); CPM-7407X1582

—Efficiency of internal targets in the accelerator at the Institute of High–Energy Physics —V. I. Gridasov, K. P. Myznikov, and V. N. Chepegin. 19(7), 922–5 (Jan. 1975); CPM-7503X0810

N

Nadgornaya, M. P.—Coaxial plasma injector with programmed injection —V. A. Burtsev, V. N. Litunovskii, and M. P. Nadgornaya. 19(6), 736–40 (Dec. 1974); CPM-7501X0736

Naida, A. P.—Gas focusing of a negative–ion beam —M. D. Gabovich, A. P. Naida, I. M. Protsenko, L. S. Simonenko, and I. A. Soloshenko. 19(4), 546–7 (Oct. 1974); CPM-7412X0330

Naidis, G. V.—Energy exchange between electrons and molecular vibrational states in resonance collisions —A. Kh. Mnatsakanyan and G. V. Naidis. 19(8), 1113–5 (Feb. 1975); CPM-7504X1537

Nalivaiko, V. I.—Multiple recording and erasure of optical information in certain glassy chalcogenides —V. V. Korsakov, V. I. Nalivaiko, V. G. Remesnik, and V. G. Tsukerman. 19(4), 565–6 (Oct. 1974); CPM-7412X0349

Nazarenko, L. M.—A transaxial lens —V. M. Kel'man, L. M. Nazarenko, and E. M. Yakushev. 19(4), 523–5 (Oct. 1974); CPM-7412X0307

Nazarenko, O. K.—Ion focusing of an electron beam in deep melting of a metal —M. D. Gabovich, V. P. Kovalenko, O. A. Metallov, O. K. Nazarenko, and S. K. Pats'ora. 19(7), 973–4 (Jan. 1975); CPM-7503X0861

—Plasma synthesis by injection of an electron beam through an ion source —V. F. Virko, M. D. Gabovich, G. S. Kirichenko, and O. K. Nazarenko. 19(11), 1418–20 (May 1975); CPM-7506X1172

Nedoseev, S. L.—Switching characteristics of a discharge in water —V. M. Kuleshov, S. L. Nedoseev, V. P. Smirnov, and A. M. Spektor. 19(1), 150–1 (Jul. 1974); CPM-7407X1662

—Effect of a high–current relativistic electron beam on a metal —B. I. Dmitrenko, L. V. Leskov, G. P. Maksimov, S. L. Nedoseev, V. V. Savichev, V. P. Smirnov, and A. M. Spektor. 19(9), 1224–5 (Mar. 1975); CPM-7505X0646

Nedospasov, A. V.—Ionization discontinuity in large–amplitude striations —A. V. Nedospasov and V. G. Petrov. 19(1), 31–4 (Jul. 1974); CPM-7407X1543

Nekrasov, F. M.—Excitation of Alfvén waves in decay instabilities —A. G. Elfimov and F. M. Nekrasov. 19(1), 9–11 (Jul. 1974); CPM-7407X1521

Nemchenko, V. I.—Production of collimated beams of high–energy electrons —V. I. Nemchenko. 19(1), 91–7 (Jul. 1974); CPM-7407X1603

Nemchinskii, V. A.—Theory of the low–voltage arc in a narrow gap —F. G. Baksht, A. A. Kostin, and V. A. Nemchinskii. 19(5), 654–7 (Nov. 1974); CPM-7501X0448

—Anomalous high emission of a nonevaporating thermionic cathode in an arc —B. Ya. Moizhes and V. A. Nemchinskii. 19(12), 1571–6 (Jun. 1975); CPM-7508X0445

—High–pressure hot–cathode arc without forced cooling —V. A. Nemchinskii. 19(12), 1577–8 (Jun. 1975); CPM-7508X0451

Nerukh, A. G.—Resonance properties of a pulsating dielectric sphere —A. G. Nerukh and N. A. Khizhnyak. 19(2), 166–8 (Aug. 1974); CPM-7408X1430

—Correction to the paper "Resonant properties of a pulsating dielectric sphere" —A. G. Nerukh and N. A. Khizhnyak. 19(12), 1641 (Jun. 1975); CPM-7508X0515

Neshpor, V. S.—Thermionic emission properties of zirconium, hafnium, and titanium nitrides in cesium vapor —M. A. Eremeev, V. S. Neshpor, A. B. Novikov, E. M. Stefanovskaya, and V. P. Fedorinov. 19(10), 1337–41 (Apr. 1975); CPM-7506X0271

Nesterovich, A. V.—Self-excited waveguide buncher —N. M. Gavrilov and A. V. Nesterovich. 19(8), 1085–6 (Feb. 1975); CPM-7504X1509

Netsvetailov, E. M.—Hot probe measurements in a rarefied streaming plasma —E. M. Netsvetailov, L. V. Nosachev, and V. V. Skvortsov. 19(12), 1579–83 (Jun. 1975); CPM-7508X0453

Neudachin, I. G.—Use of the distribution function to describe free molecular beams —I. G. Neudachin, B. T. Porodnov, and P. E. Suetin. 19(4), 511–4 (Oct. 1974); CPM-7412X0295

Nevdakha, G. G.—Effect of the adsorption rate on the diffusion of deuterium through nickel —Yu. I. Belyakov, Yu. I. Zvezdin, A. A. Kurdyumov, and G. G. Nevdakha. 19(7), 956–8 (Jan. 1975); CPM-7503X0844

Nevolin, V. N.—Neutral particles from the interaction of laser radiation with a solid target —Yu. A. Bykovskii, N. M. Vasil'ev, I. D. Laptev, and V. N. Nevolin. 19(12), 1635 (Jun. 1975); CPM-7508X0509

Nikitin, K. A.—Electrical conductivity of a pseudoliquefied layer in an electric field —V. V. Gal', V. I. Konov, and K. A. Nikitin. 19 (9), 1214–5 (Mar. 1975); CPM-7505X0636

Nikitin, M. M.—Coherent phase oscillations of electrons in a synchrotron —M. M. Nikitin. 19(12), 1633–4 (Jun. 1975); CPM-7508X0507

Nikitinskii, V. A.—Ion emission into vacuum from a discharge in crossed electric and magnetic fields —V. A. Nikitinskii and A. S. Zakharov. 19(6), 839–40 (Dec. 1974); CPM-7501X0839

Nikolaev, V. M.—Effect of a magnetic field on spontaneous mode-locking in a He—Ne laser ($\Lambda=0.63\mu$) —V. Yu. Petrun'kin, V. M. Nikolaev, O. I. Kotov, and B. V. L'vov. 19(12), 1612–3 (Jun. 1975); CPM-7508X0486

Nikolenko, D. M.—Electron spectrometer for electric excitation of nuclei in a storage ring —D. M. Nikolenko and S. G. Popov. 19 (2), 280–3 (Aug. 1974); CPM-7408X1544

Nilov, E. V.—Pulsed neodymium-glass laser with periodic Q switching —T. A. Kuzovkova, E. V. Nilov, V. A. Rusov, I. N. Semenov, and A. A. Chertkov. 19(4), 503–5 (Oct. 1974); CPM-7412X0287

Niskonen, I. S.—High-frequency discharge in a mercury—helium mixture —S. D. Vagner, Yu. M. Kagan, A. I. Konstantinov, and I. S. Niskonen. 19(7), 898–900 (Jan. 1975); CPM-7503X0786

Nizhnik, L. P.—Rectangular conducting wedge in a moving electromagnetic field —I. D. Maergoiz and L. P. Nizhnik. 19(10), 1281–6 (Apr. 1975); CPM-7506X0215

Nosachev, L. V.—Hot probe measurements in a rarefied streaming plasma —E. M. Netsvetailov, L. V. Nosachev, and V. V. Skvortsov. 19(12), 1579–83 (Jun. 1975); CPM-7508X0453

Novikov, A. B.—Thermionic emission properties of zirconium, hafnium, and titanium nitrides in cesium vapor —M. A. Eremeev, V. S. Neshpor, A. B. Novikov, E. M. Stefanovskaya, and V. P. Fedorinov. 19(10), 1337–41 (Apr. 1975); CPM-7506X0271

Nuller, T. A.—Dependence of the basic parameters of $Al_xGa_{1-x}As$—GaAs solar converters on temperature and optical intensity —E. B. Vinogradova, M. B. Kagan, N. S. Koroleva, T. L. Lyubashevskaya, and T. A. Nuller. 19(10), 1378–81 (Apr. 1975); CPM-7506X0312

Nurmanov, M. Sh.—Symmetric multielectrode tubular electrostatic lenses —L. G. Glikman, V. M. Kel'man, and M. Sh. Nurmanov. 19(5), 680–2 (Nov. 1974); CPM-7501X0474

O

Ogienko, V. V.—Secondary-electron energy in a resonance discharge in a three-electrode system —Yu. A. Kulikov, V. V. Ogienko, and Yu. M. Trifonov. 19(8), 1090–2 (Feb. 1975); CPM-7504X1514

Ogorodnikov, S. N.—Ion-optical system for shaping high-current ion beams —S. D. Grishin, V. F. Kuzovlev, R. V. Orlov, and S. N. Ogorodnikov. 19(11), 1462–4 (May 1975); CPM-7506X1216

Oraevskii, A. N.—Photochemical waves in a medium with a branch-chain conversion mechanism —A. N. Oraevskii, V. P. Pimenov, and V. A. Shcheglov. 19(6), 782–6 (Dec. 1974); CPM-7501X0782

Orlov, R. V.—Ion-optical system for shaping high-current ion beams —S. D. Grishin, V. F. Kuzovlev, R. V. Orlov, and S. N. Ogorodnikov. 19(11), 1462–4 (May 1975); CPM-7506X1216

Osadin, B. A.—Condensation of a dense vapor flow —V. G. Dneprovskii, B. A. Osadin, and N. V. Rusakov. 19(2), 271–4 (Aug. 1974); CPM-7408X1535

—Effect of focusing conditions on the morphology of surface films produced with a laser —V. G. Dneprovskii and B. A. Osadin. 19 (2), 275–7 (Aug. 1974); CPM-7408X1539

—Condensation of an erosion plasma —B. A. Osadin and N. V. Rusakov. 19(2), 299–300 (Aug. 1974); CPM-7408X1563

Osipov, A. I.—Gas cooling in transmission of high-power CO_2 laser radiation through the atmosphere —B. F. Gordiets, A. I. Osipov, and R. V. Khokhlov. 19(5), 669–72 (Nov. 1974); CPM-7501X0463

Osipov, Yu. I.—New method for obtaining probe characteristics —Yu. I. Osipov. 19(2), 296–8 (Aug. 1974); CPM-7408X1560

Osoka, V. P.—Discharge in a cylindrical diode with surface ionization —V. P. Osoka and A. V. Potarov. 19(9), 1200–4 (Mar. 1975); CPM-7505X0622

Ostretsov, I. N.—Current density of thermionic-field emission into a plasma at moderate fields —I. N. Ostretsov, V. A. Petrosov, A. A. Porotnikov, and B. B. Rodnevich. 19(5), 707–8 (Nov. 1974); CPM-7501X0501

Ostrovskaya, G. V.—Investigation of spatial distributions in a laser-produced plasma by $H\alpha$ absorption —G. V. Ostrovskaya and N. A. Pobedonostseva. 19(3), 424–6 (Sep. 1974); CPM-7412X1110

Ostrovskii, Yu. I.—Hologram interferometry for vibration analysis —V. S. Listovets and Yu. I. Ostrovskii. 19(7), 847–60 (Jan. 1975); CPM-7503X0735

Osvenskii, V. B.—Crystal defects of heterostructures of AlAs–GaAs solid solutions and effect on the characteristics of injection lasers —L. V. Druzhinina, V. T. Bublik, L. M. Dolginov, P. G. Eliseev, M. P. Kerbelev, V. B. Osvenskii, I. Z. Pinsker, and M. G. Shumskii. 19(7), 935–9 (Jan. 1975); CPM-7503X0823

Ovchinnikov, I. T.—Investigating prebreakdown fields in water by means of the Kerr effect —I. T. Ovchinnikov, K. V. Yanshin, and É. V. Yanshin. 19(2), 294–5 (Aug. 1974); CPM-7408X1558

Ovchinnikov, V. L.—Excitation collisions between magnesium ions and inert gas atoms —V. L. Ovchinnikov, O. B. Shpenik, and I. P. Zapesochnyi. 19(3), 382–4 (Sep. 1974); CPM-7412X1068

Ovchinnikov, V. M.—Laser compensation for thermal distortion in optical pumping —V. K. Zaitsev, V. A. Il'inskii, A. M. Marugin, and V. M. Ovchinnikov. 19(11), 1480–1 (May 1975); CPM-7506X1234

P

Padalka, V. G.—Plasma confinement in a time-increasing multipole magnetic field —V. G. Padalka and N. S. Repalov. 19(1), 121–2 (Jul. 1974); CPM-7407X1633

—Focusing of a neutralized ion beam by a plasma-optics system —I. I. Demidenko, N. S. Lomino, A. I. Morozov, and V. G. Padalka. 19(3), 347–50 (Sep. 1974); CPM-7412X1033

—Effect of rf ionization on Hall-current plasma accelerator —I. I. Demidenko, N. S. Lomino, A. I. Morozov, and V. G. Padalka. 19 (12), 1560–3 (Jun. 1975); CPM-7508X0434

Pakhomov, V. I.—Quasilinear theory of beam-generated surface waves in a plasma —V. I. Pakhomov and V. L. Sizonenko. 19(5), 630–4 (Nov. 1974); CPM-7501X0424

Paleev, V. I.—Surface-ionization determination of the electron affinities of silver and gold —É. Ya. Zandberg, A. G. Kamenev, and V. I. Paleev. 19(3), 385–9 (Sep. 1974); CPM-7412X1071

—Determination of ionization potentials and electron affinities of certain elements by extrapolation —A. G. Kamenev, É. Ya. Zandberg, and V. I. Paleev. 19(7), 940–1 (Jan. 1975); CPM-7503X0828

Palkin, S. N.—Statistical characteristics of the turbulent wake behind a supersonic sphere —V. G. Ivanov, G. I. Mishin, and S. N. Palkin. 19(4), 543–5 (Oct. 1974); CPM-7412X0327

Pamfilov, A. V.—A useful function in the thermodynamics of irreversible processes —A. V. Pamfilov, A. I. Lopushanskaya, and L. B. Tsvetkova. 19(4), 535–7 (Oct. 1974); CPM-7412X0319

Panasyuk, V. S.—Extraction of synchroton radiation from a cyclic electron accelerator with a strong magnetic field —V. I. Kvochka, V. S. Panasyuk, V. F. Romanovskii, L. N. Samoilov, A. A. Sokolov, B. M. Stepanov, and Yu. M. Tereshkin. 19(6), 762–6 (Dec. 1974); CPM-7501X0762

Panchenko, I. P.—Transmission of a high–current relativistic beam through a gas —Yu. V. Tkach, I. I. Magda, G. V. Skachek, S. S. Pushkarev, and I. P. Panchenko. **19**(3), 412–3 (Sep. 1974); CPM-7412X1098

Pankratov, I. M.—Nonlinear behavior of monochromatic surface waves excited by a beam —A. B. Kitsenko, I. M. Pankratov, and K. N. Stepanov. **19**(11), 1505–6 (May 1975); CPM-7506X1259

Pankratov, S. G.—Radiation of electromagnetic waves by a modulated electron beam —S. G. Pankratov. **19**(9), 1248–50 (Mar. 1975); CPM-7505X0670

Parilis, É. S.—Doppler profile of an atomic line to the differential excitation cross section —É. S. Parilis and V. Kh. Ferleger. **19**(10), 1367–70 (Apr. 1975); CPM-7506X0301

Pashchenko, A. V.—Wave interaction in a thin plasma sheath —A. V. Pashchenko and B. N. Rutkevich. **19**(6), 726–31 (Dec. 1974); CPM-7501X0726

—Two-stream flow in a thin plasma slab —A. V. Pashchenko and B. N. Rutkevich. **19**(12), 1538–40 (Jun. 1975); CPM-7508X0412

Pashchenko, V. P.—Steady-state operation of a surface-ionization thermionic converter —N. V. Volkov, Yu. K. Gus'kov, Yu. I. Kostikov, and V. P. Pashchenko. **19**(8), 1129–30 (Feb. 1975); CPM-7504X1553

—Analytic model of the cesium arc —V. P. Pashchenko, V. L. Mironovich, and I. P. Stakhanov. **19**(10), 1332–6 (Apr. 1975); CPM-7506X0266

Pashnev, V. K.—Hydrodynamic stability of the Uragan stellarator —V. M. Zalkind, Yu. K. Kuznetsov, V. K. Pashnev, and V. M. Tonkopryad. **19**(8), 1123–5 (Feb. 1975); CPM-7504X1547

Paskalev, K. K.—Gas temperature in the positive column of a medium-β helium discharge —Yu. M. Kagan and K. K. Paskalev. **19**(12), 1601–3 (Jun. 1975); CPM-7508X0475

—Temperature and electron density in the positive column of a medium-pressure helium discharge —Yu. M. Kagan and K. K. Paskalev. **19**(12), 1604–5 (Jun. 1975); CPM-7508X0478

Paslen, V. N.—Formation of molecular ions in an alkali discharge —V. N. Paslen and A. M. Przhonskii. **19**(5), 705–6 (Nov. 1974); CPM-7501X0499

Pasynok, A. I.—Parametric instability of an electron beam in a magnetic field —A. I. Pasynok and N. S. Repalov. **19**(2), 177–80 (Aug. 1974); CPM-7408X1441

—Parametric excitation of surface waves in a spatially modulated electron beam —A. I. Pasynok and N. S. Repalov. **19**(4), 572–3 (Oct. 1974); CPM-7412X0356

Pats'ora, S. K.—Ion focusing of an electron beam in deep melting of a metal —M. D. Gabovich, V. P. Kovalenko, O. A. Metallov, O. K. Nazarenko, and S. K. Pats'ora. **19**(7), 973–4 (Jan. 1975); CPM-7503X0861

Paverman, V. S.—Low-frequency helical instability in a high-frequency electric field —V. S. Paverman and D. D. Tskhakaya. **19**(11), 1508–9 (May 1975); CPM-7506X1262

—Parametric excitation of helicon waves in a plasma by modulated radio frequency waves —V. S. Paverman and D. D. Tskhakya. **19** (12), 1629–30 (Jun. 1975); CPM-7508X0503

Pavlenko, Yu. G.—Microwave maser with nonrelativistic electrons —A. S. Dement'ev and Yu. G. Pavlenko. **19**(5), 694–5 (Nov. 1974); CPM-7501X0488

Pavlova, A. D.—Energy dependence of the focusing of ions by crystals —E. S. Mashkova, V. A. Molchanov, and A. D. Pavlova. **19**(4), 540 (Oct. 1974); CPM-7412X0324

Pazin, K. N.—Magnetic-field transport of a high-current electron beam —A. V. Agafonov, V. S. Voronin, A. N. Lebedev, and K. N. Pazin. **19**(9), 1188–92 (Mar. 1975); CPM-7505X0610

Peletminskaya, V. G.—Magnetic topography of toroidal systems —M. N. Skoblik, V. E. Ziser, A. V. Georgievskii, and V. G. Peletminskaya. **19**(10), 1277–80 (Apr. 1975); CPM-7506X0211

Perebeinos, V. V.—Dynamics and emission of coaxial plasma shells in air —A. F. Aleksandrov, V. V. Perebeinos, A. T. Savichev, and I. B. Timofeev. **19**(1), 38–42 (Jul. 1974); CPM-7407X1550

—Initial stage of a high-current discharge in air —A. F. Aleksandrov, V. V. Perebeinos, A. T. Savichev, and I. B. Timofeev. **19**(11), 1490–1 (May 1975); CPM-7506X1244

Peregud, B. P.—Plasma diffusion in the Tornado device —A. N. Kozyrev and B. P. Peregud. **19**(4), 468–74 (Oct. 1974); CPM-7412X0252

Perel'man, T. L.—Fundamentals of heat-pipe theory and design —M. M. Levitan and T. L. Perel'man. **19**(8), 983–95 (Feb. 1975); CPM-7504X1407

Perepelkin, S. S.—Shielding properties of superconducting shields —S. I. Bondarenko, S. S. Vinogradov, G. A. Gogadze, S. S. Perepelkin, and V. I. Sheremet. **19**(6), 824–8 (Dec. 1974); CPM-7501X0824

Perlin, A. S.—High–current pulsed electron accelerator with an annular beam —M. I. Avramenko, V. A. Glukhikh, O. A. Gusev, E. G. Komar, O. L. Komarov, V. S. Kuznetsov, A. S. Perlin, and M. P. Svin'in. **19**(3), 368–70 (Sep. 1974); CPM-7412X1054

Petrosov, V. A.—Current density of thermionic–field emission into a plasma at moderate fields —I. N. Ostretsov, V. A. Petrosov, A. A. Porotnikov, and B. B. Rodnevich. **19**(5), 707–8 (Nov. 1974); CPM-7501X0501

Petrov, V. G.—Ionization discontinuity in large–amplitude striations —A. V. Nedospasov and V. G. Petrov. **19**(1), 31–4 (Jul. 1974); CPM-7407X1543

Petrov, V. V.—Optical methods for studying amplification of elastic surface waves in a stratified system —I. B. Yakovkin, V. V. Petrov, and S. V. Bogdanov. **19**(9), 1242–5 (Mar. 1975); CPM-7505X0664

Petrunin, V. I.—Resonator with azimuthally varying end plates —M. F. Vorogushin and V. I. Petrunin. **19**(6), 767–9 (Dec. 1974); CPM-7501X0767

—Azimuthal and vertical motion in an accelerator with azimuthally varying electric field —M. F. Vorogushin and V. I. Petrunin. **19**(6), 770–2 (Dec. 1974); CPM-7501X0770

—Phase motion of particles in an accelerator with an azimuthally varying electric field —M. F. Vorogushin and V. I. Petrunin. **19**(7), 926–9 (Jan. 1975); CPM-7503X0814

Petrun'kin, V. Yu.—Effect of a magnetic field on spontaneous mode-locking in a He—Ne laser ($\Lambda=0.63\mu$) —V. Yu. Petrun'kin, V. M. Nikolaev, O. I. Kotov, and B. V. L'vov. **19**(12), 1612–3 (Jun. 1975); CPM-7508X0486

Piliya, A. D.—Absolute decay instability of low–frequency waves in an inhomogeneous plasma —A. D. Piliya and V. I. Fedorov. **19**(5), 686 (Nov. 1974); CPM-7501X0480

Pimenov, V. P.—Photochemical waves in a medium with a branch–chain conversion mechanism —A. N. Oraevskii, V. P. Pimenov, and V. A. Shcheglov. **19**(6), 782–6 (Dec. 1974); CPM-7501X0782

Pimkin, V. A.—Breakdown caused by electron bombardment of the surface of an alloy electrode —N. V. Belan, G. I. Kostyuk, and V. A. Pimkin. **19**(6), 802–3 (Dec. 1974); CPM-7501X0802

Pinchuk, V. P.—Atomic recombination on a solid surface —V. P. Pinchuk, A. N. Gorban', and V. G. Kornich. **19**(6), 808–10 (Dec. 1974); CPM-7501X0808

Pinsker, I. Z.—Crystal defects of heterostructures of AlAs–GaAs solid solutions and effect on the characteristics of injection lasers —L. V. Druzhinina, V. T. Bublik, L. M. Dolginov, P. G. Eliseev, M. P. Kerbelev, V. B. Osvenskii, I. Z. Pinsker, and M. G. Shumskii. **19**(7), 935–9 (Jan. 1975); CPM-7503X0823

Piterskii, V. V.—Measurement of plasma electron temperature with a sinusoidal probe potential —B. I. Kanaev, V. V. Piterskii, and E. E. Yushmanov. **19**(11), 1421–3 (May 1975); CPM-7506X1175

Plakhov, A. G.—Scattering of an electron beam in a straight *dc* turbulent plasma —Yu. P. Golovanov, L. P. Zakatov, A. S. Kingsep, and A. G. Plakhov. **19**(8), 1046–9 (Feb. 1975); CPM-7504X1470

Plis, A. I.—Radiation from a charged particle moving close to an anisotropic dielectric —A. I. Plis and N. M. Safikhodzhaev. **19**(7), 865–7 (Jan. 1975); CPM-7503X0753

—Gas polymerization wave excited by monochromatic light —A. I. Plis and V. A. Shcheglov. **19**(9), 1262–3 (Mar. 1975); CPM-7505X0684

Pliskovskii, V. Ya.—Use of a field-emission microscope to measure the pressure of pump oil —V. Ya. Pliskovskii, M. S. Sukonnik, and V. A. Shishkin. **19**(10), 1347–51 (Apr. 1975); CPM-7506X0281

Pliss, N. S.—Simulation of ion scattering on diatomic molecules —M. L. Aleksandrov, N. S. Pliss, and A. P. Shcherbakov. **19**(3), 394–5 (Sep. 1974); CPM-7412X1080

—Monte Carlo analysis of ion scattering in a mass spectrometer —M. L. Aleksandrov, L. N. Gall', and N. S. Pliss. **19**(6), 817–9 (Dec. 1974); CPM-7501X0817

Plyutto, A. A.—Pulsed ion beams from a high-current plasma diode —B. A. Tskhadaya, A. A. Plyutto, and K. V. Suladze. **19**(8), 1108–9 (Feb. 1975); CPM-7504X1532

Pobedonostseva, N. A.—Investigation of spatial distributions in a laser–produced plasma by Hα absorption —G. V. Ostrovskaya and N. A. Pobedonostseva. **19**(3), 424–6 (Sep. 1974); CPM-7412X1110

Podteregera, N. N.—Plasma equilibrium and confinement in a poloidal heliotron configuration. I —V. G. Zykov, V. I. Karpukhin, Yu. F. Lonin, N. N. Podteregera, N. I. Rudnev, and V. T. Tolok. 19(8), 1063–8 (Feb. 1975); CPM-7504X1487
—Plasma equilibrium and confinement in a poloidal heliotron configuration. II —V. G. Zykov, V. I. Karpukhin, Yu. F. Lonin, N. N. Podteregera, N. I. Rudnev, A. Y. Skibenko, V. T. Tolok, and I. P. Fomin. 19(8), 1069–72 (Feb. 1975); CPM-7504X1493
Pokhmel'nykh, L. A.—Radio-frequency absorption in a plasma confined by rf plugs —K. S. Golovanivskii, V. D. Dougar-Jabon, and L. A. Pokhmel'nykh. 19(11), 1484–5 (May 1975); CPM-7506X1238
Polenov, B. V.—Electrostatic analyzer for wide beams —V. G. Kovalenko and B. V. Polenov. 19(4), 561–2 (Oct. 1974); CPM-7412X0345
Polyakov, V. M.—Experimental investigation of microwave radiation produced by hypersonic flows —V. A. Lyutomskii, V. M. Polyakov, and V. G. Testov. 19(4), 483–5 (Oct. 1974); CPM-7412X0267
Polyanichev, A. N.—Recombination in an expanding plasma —Yu. A. Bykovskii, N. N. Degtyarenko, V. F. Elesin, V. E. Kondrashov, E. E. Lovetskii, A. N. Polyanichev, and V. S. Fetisov. 19(1), 43–8 (Jul. 1974); CPM-7407X1555
—Expansion of a recombining plasma in vacuum —E. E. Lovetskii, A. N. Polyanichev, and V. S. Fetisov. 19(5), 647–50 (Nov. 1974); CPM-7501X0441
Pomelov, Ya. A.—Effects of ion microfields on emission of an arc cathode —A. M. Dorodnov, V. B. Davydov, A. V. Kozyrev, and Ya. A. Pomelov. 19(3), 390–3 (Sep. 1974); CPM-7412X1076
Pontekorvo, D. B.—Effects due to streamer shape —É. D. Lozanskii and D. B. Pontekorvo. 19(11), 1432–3 (May 1975); CPM-7506X1186
Poplavko, Yu. M.—Dispersion of the dielectric constant of crystalline KH_2PO_4 near the "soft" mode frequency —V. V. Meriakri, Yu. M. Poplavko, and E. F. Ushatkin. 19(5), 703–4 (Nov. 1974); CPM-7501X0497
Popov, O. Ya.—Analysis of magnetic deflection systems —O. M. Vovk and O. Ya. Popov. 19(11), 1504 (May 1975); CPM-7506X1258
Popov, S. G.—Electron spectrometer for electric excitation of nuclei in a storage ring —D. M. Nikolenko and S. G. Popov. 19(2), 280–3 (Aug. 1974); CPM-7408X1544
Popov, Yu. V.—Time characteristics of the near radiation field of the injection laser —Zh. I. Alferov, V. N. Deryagin, L. E. Marasin, Yu. V. Popov, and E. L. Portnoi. 19(4), 548 (Oct. 1974); CPM-7412X0332
Popytaev, A. N.—Interaction of intense laser radiation with solid targets —L. V. Dubovoi, V. D. Dyatlov, V. I. Kryzhanovskii, A. A. Mak, R. N. Medvedev, A. N. Popytaev, V. A. Serebryakov, V. N. Sizov, and A. D. Starikov. 19(11), 1477–9 (May 1975); CPM-7506X1231
Porodnov, B. T.—Use of the distribution function to describe free molecular beams —I. G. Neudachin, B. T. Porodnov, and P. E. Suetin. 19(4), 511–4 (Oct. 1974); CPM-7412X0295
—Flow of low-density gases in a capillary grid —B. T. Porodnov, V. D. Akin'shin, V. I. Kichaev, S. F. Borisov, and P. E. Suetin. 19(4), 515–8 (Oct. 1974); CPM-7412X0299
Porotnikov, A. A.—Current density of thermionic-field emission into a plasma at moderate fields —I. N. Ostretsov, V. A. Petrosov, A. A. Porotnikov, and B. B. Rodnevich. 19(5), 707–8 (Nov. 1974); CPM-7501X0501
Portnoi, E. L.—Time characteristics of the near radiation field of the injection laser —Zh. I. Alferov, V. N. Deryagin, L. E. Marasin, Yu. V. Popov, and E. L. Portnoi. 19(4), 548 (Oct. 1974); CPM-7412X0332
—Characteristics of diffraction gratings obtained by photoetching of semiconductor surfaces —L. V. Belyakov, D. N. Goryachev, M. N. Mizerov, and E. L. Portnoi. 19(6), 837–8 (Dec. 1974); CPM-7501X0837
Portnyagin, A. I.—Thermal effect of continuous laser radiation on optically transparent media —N. S. Bardina, A. I. Portnyagin, M. Yu. Sklyarov, and A. A. Churin. 19(4), 491–4 (Oct. 1974); CPM-7412X0275
Potarov, A. V.—Discharge in a cylindrical diode with surface ionization —V. P. Osoka and A. V. Potarov. 19(9), 1200–4 (Mar. 1975); CPM-7505X0622
Prilezhaev, D. S.—Lasing properties of Yb^{3+} and Er^{3+} glass laser pumped by a laser —V. N. Kalinin, A. A. Mak, D. S. Prilezhaev, and V. A. Fromzel'. 19(6), 835–6 (Dec. 1974); CPM-7501X0835
Privalov, V. E.—Mode coupling in a double-anode discharge —Yu. G. Zakharenko and V. E. Privalov. 19(7), 980–2 (Jan. 1975); CPM-7503X0868
Privezentsev, V. I.—Investigation of a plasma focus with a time-resolved laser interferometer —I. M. Zolototrubov, I. P. Skoblik, A. G. Tolstolutskii, and V. I. Privezentsev. 19(8), 1061–2 (Feb. 1975); CPM-7504X1485
Prokopov, A. V.—Microwave discharge in argon —E. V. Belousov, A. S. Bryukhovetskii, and A. V. Prokopov. 19(1), 53–6 (Jul. 1974); CPM-7407X1565
—Effect of ionization and excitation on the penetration of an electromagnetic wave into a weakly ionized plasma —A. G. Boev and A. V. Prokopov. 19(7), 901–4 (Jan. 1975); CPM-7503X0789
Protasov, Yu. S.—Use of plasma accelerator for optical pumping of lasers —N. P. Kozlov and Yu. S. Protasov. 19(3), 358–60 (Sep. 1974); CPM-7412X1044
—Formation of a plasma focus in a plasma erosion accelerator. II. Energy characteristics of the dense plasma focus —N. P. Kozlov, L. V. Leskov, Yu. S. Protasov, and V. I. Khvesyuk. 19(12), 1558–9 (Jun. 1975); CPM-7508X0432
Protsenko, I. M.—Gas focusing of a negative-ion beam —M. D. Gabovich, A. P. Naida, I. M. Protsenko, L. S. Simonenko, and I. A. Soloshenko. 19(4), 546–7 (Oct. 1974); CPM-7412X0330
Pruzhanovskii, V. A.—Round metal-optical waveguide filled with a two-layer dielectric —V. A. Pruzhanovskii. 19(1), 3–8 (Jul. 1974); CPM-7407X1515
Przhonskii, A. M.—Formation of molecular ions in an alkali discharge —V. N. Paslen and A. M. Przhonskii. 19(5), 705–6 (Nov. 1974); CPM-7501X0499
Puchkova, N. G.—Exact solutions of the nonlinear electrodynamic equations —N. G. Puchkova and A. F. Kulish. 19(12), 1614–5 (Jun. 1975); CPM-7508X0488
Pushkarev, S. S.—Transmission of a high-current relativistic beam through a gas —Yu. V. Tkach, I. I. Magda, G. V. Skachek, S. S. Pushkarev, and I. P. Panchenko. 19(3), 412–3 (Sep. 1974); CPM-7412X1098
Putvinskii, S. V.—Drift instability in a weakly ionized plasma —S. V. Putvinskii and A. V. Timofeev. 19(10), 1295–9 (Apr. 1975); CPM-7506X0229
Pyatak, A. I.—Instabilities in a finite-β plasma with transverse current. I —A. I. Pyatak and V. L. Sizonenko. 19(5), 635–9 (Nov. 1974); CPM-7501X0429
—Instabilities in a finite-β plasma with transverse current. II —A. I. Pyatak and V. L. Sizonenko. 19(5), 640–4 (Nov. 1974); CPM-7501X0434
—High-frequency instabilities in an inhomogeneous, anisotropic finite-β plasma —V. D. Egorenkov and A. I. Pyatak. 19(9), 1160–2 (Mar. 1975); CPM-7505X0582

R

Radchenko, Yu. F.—Development of an inhibited glow discharge —Yu. A. Bystrov, S. A. Ivanov, and Yu. F. Radchenko. 19(11), 1447–8 (May 1975); CPM-7506X1201
Ranyuk, A. I.—Kinetic plasma instabilities excited by a monoenergetic beam —A. I. Ranyuk and V. L. Sizonenko. 19(5), 628–9 (Nov. 1974); CPM-7501X0422
Razdobarin, G. T.—Diagnostics of a laser-produced plasma by a scattering method using an electron-optical image converter —E. A. Burunov, G. M. Malyshev, G. T. Razdobarin, and V. V. Semenov. 19(1), 66–9 (Jul. 1974); CPM-7407X1578
Regirer, S. A.—Magnetohydrodynamic channel flow in a tapered magnetic field —S. A. Regirer. 19(7), 874–7 (Jan. 1975); CPM-7503X0762
Rekova, L. P.—Elimination of carbon impurities from platinum by heating in an oxygen atmosphere —L. P. Rekova, V. V. Mozgin, L. N. Zvyagintseva, V. N. Bondarenko, and Ya. M. Fogel'. 19(11), 1465–7 (May 1975); CPM-7506X1219
Remesnik, V. G.—Multiple recording and erasure of optical information in certain glassy chalcogenides —V. V. Korsakov, V. I. Nalivaiko, V. G. Remesnik, and V. G. Tsukerman. 19(4), 565–6 (Oct. 1974); CPM-7412X0349
Repalov, N. S.—Plasma confinement in a time-increasing multipole magnetic field —V. G. Padalka and N. S. Repalov. 19(1), 121–2 (Jul. 1974); CPM-7407X1633

—Parametric instability of an electron beam in a magnetic field —A. I. Pasynok and N. S. Repalov. 19(2), 177–80 (Aug. 1974); CPM-7408X1441

—Parametric excitation of surface waves in a spatially modulated electron beam —A. I. Pasynok and N. S. Repalov. 19(4), 572–3 (Oct. 1974); CPM-7412X0356

—Parametric instability of a spatially moderated electron beam in a magnetic field —N. S. Repalov and V. F. Tyrnov. 19(7), 871–3 (Jan. 1975); CPM-7503X0759

Reshenov, S. P.—Nonequilibrium ionization in the cathode region of a high-pressure arc —S. P. Reshenov. 19(8), 1073–5 (Feb. 1975); CPM-7504X1497

Reshetnyak, S. A.—Plasma dynamic lasers —S. A. Reshetnyak and L. A. Shelepin. 19(8), 1076–80 (Feb. 1975); CPM-7504X1500

Reznikov, V. P.—Electron energy spectrum in high-energy nanosecond accelerators —V. V. Kremnev, G. A. Mesyats, and V. P. Reznikov. 19(10), 1342–4 (Apr. 1975); CPM-7506X0276

Rikenglaz, L. É.—Microwave propagation in a low-loss dielectric —L. É. Rikenglaz. 19(6), 713–4 (Dec. 1974); CPM-7501X0713

Rodichkin, V. A.—Laser-initiated vacuum discharge —V. P. Kovalenko, A. A. Makarevich, V. A. Rodichkin, and A. M. Timonin. 19(11), 1429–31 (May 1975); CPM-7506X1183

Rodnevich, B. B.—Current density of thermionic–field emission into a plasma at moderate fields —I. N. Ostretsov, V. A. Petrosov, A. A. Porotnikov, and B. B. Rodnevich. 19(5), 707–8 (Nov. 1974); CPM-7501X0501

Rogozinskii, V. G.—Two-omegatron study of the pumping characteristics of an NÉM-300 magnetic discharge pump for a mixture of gases —M. K. Bulgakov and V. G. Rogozinskii. 19(3), 427–8 (Sep. 1974); CPM-7412X1113

—Titanium-pump system for hydrogen —K. G. Mirzoev, V. G. Rogozinskii, and V. L. Ushkov. 19(3), 432–3 (Sep. 1974); CPM-7412X1118

Rokhinson, É. Kh.—Possible electrohydrodynamic effects in electrolytes —E. Z. Gak, É. Kh. Rokhinson, and N. F. Bondarenko. 19(5), 676–7 (Nov. 1974); CPM-7501X0470

Romanov, P. V.—Numerical experiments on electron bombardment in crossed fields —P. V. Romanov and A. S. Roshal'. 19(9), 1221–3 (Mar. 1975); CPM-7505X0643

Romanov, S. S.—Diffusion of quasistationary helical magnetic fields into the interior of cylindrical chambers. II. —V. F. Aleksin and S. S. Romanov. 19(9), 1171–3 (Mar. 1975); CPM-7505X0593

Romanov, Yu. A.—Surface waves in periodic plasma systems —V. F. Dryakhlushin and Yu. A. Romanov. 19(7), 883–6 (Jan. 1975); CPM-7503X0771

Romanovskii, V. F.—Extraction of synchroton radiation from a cyclic electron accelerator with a strong magnetic field —V. I. Kvochka, V. S. Panasyuk, V. F. Romanovskii, L. N. Samoilov, A. A. Sokolov, B. M. Stepanov, and Yu. M. Tereshkin. 19(6), 762–6 (Dec. 1974); CPM-7501X0762

Roshal', A. S.—Numerical experiments on electron bombardment in crossed fields —P. V. Romanov and A. S. Roshal'. 19(9), 1221–3 (Mar. 1975); CPM-7505X0643

Roshchin, A. A.—Proton extraction from the 70-GeV accelerator for the Ludmila liquid-hydrogen chamber (extraction system S) —A. A. Aseev, A. I. Drozhdin, B. A. Zelenov, É. A. Merker, L. L. Moizhes, K. P. Myznikov, A. A. Roshchin, V. M. Tatarenko, M. A. Kholodenko, A. D. Artemov, L. N. Vaulin, V. I. Gordin, I. I. Kovalevskii, V. N. Rozhkov, M. M. Suvorov, A. S. Sudarushkin, and V. I. Chuiko. 19(1), 70–6 (Jul. 1974); CPM-7407X1582

Rozhkov, A. M.—Plasma decay instability in crossed fields —V. I. Farenik, V. V. Vlasov, A. M. Rozhkov, and A. A. Kozharin. 19(8), 1116–7 (Feb. 1975); CPM-7504X1540

—Ion energy spectra and collective effects in a Penning ion source —V. I. Farenik, V. V. Vlasov, A. M. Rozhkov, and A. A. Kozharin. 19(9), 1258–9 (Mar. 1975); CPM-7505X0680

Rozhkov, V. N.—Proton extraction from the 70-GeV accelerator for the Ludmila liquid-hydrogen chamber (extraction system S) —A. A. Aseev, A. I. Drozhdin, B. A. Zelenov, É. A. Merker, L. L. Moizhes, K. P. Myznikov, A. A. Roshchin, V. M. Tatarenko, M. A. Kholodenko, A. D. Artemov, L. N. Vaulin, V. I. Gordin, I. I. Kovalevskii, V. N. Rozhkov, M. M. Suvorov, A. S. Sudarushkin, and V. I. Chuiko. 19(1), 70–6 (Jul. 1974); CPM-7407X1582

Rudenko, N. S.—Streamer propagation after the voltage termination in a streamer chamber —N. S. Rudenko and V. I. Smetanin. 19 (12), 1616–7 (Jun. 1975); CPM-7508X0490

Rudnev, N. I.—Plasma equilibrium and confinement in a poloidal heliotron configuration. I —V. G. Zykov, V. I. Karpukhin, Yu. F. Lonin, N. N. Podteregera, N. I. Rudnev, and V. T. Tolok. 19(8), 1063–8 (Feb. 1975); CPM-7504X1487

—Plasma equilibrium and confinement in a poloidal heliotron configuration. II —V. G. Zykov, V. I. Karpukhin, Yu. F. Lonin, N. N. Podteregera, N. I. Rudnev, A. Y. Skibenko, V. T. Tolok, and I. P. Fomin. 19(8), 1069–72 (Feb. 1975); CPM-7504X1493

Rukhadze, A. A.—Radiating discharges confined by walls —A. F. Aleksandrov, I. S. Marshak, and A. A. Rukhadze. 19(3), 308–14 (Sep. 1974); CPM-7412X0994

—Excitation of surface electromagnetic waves in a plasma cylinder surrounded by a hollow electron beam —O. V. Dolzhenko, A. V. Zosimov, and A. A. Rukhadze. 19(5), 618–21 (Nov. 1974); CPM-7501X0412

Rusakov, N. V.—Condensation of a dense vapor flow —V. G. Dneprovskii, B. A. Osadin, and N. V. Rusakov. 19(2), 271–4 (Aug. 1974); CPM-7408X1535

—Condensation of an erosion plasma —B. A. Osadin and N. V. Rusakov. 19(2), 299–300 (Aug. 1974); CPM-7408X1563

Rusanov, V. D.—Acceleration of plasma electrons in strong electric fields —Z. A. Al'bikov, M. I. Ivanov, V. I. Kazacha, O. V. Kozlov, V. D. Rusanov, and S. S. Sobolev. 19(11), 1498–9 (May 1975); CPM-7506X1252

Rusov, V. A.—Pulsed neodymium–glass laser with periodic Q switching —T. A. Kuzovkova, E. V. Nilov, V. A. Rusov, I. N. Semenov, and A. A. Chertkov. 19(4), 503–5 (Oct. 1974); CPM-7412X0287

Rutkevich, B. N.—Wave interaction in a thin plasma sheath —A. V. Pashchenko and B. N. Rutkevich. 19(6), 726–31 (Dec. 1974); CPM-7501X0726

—Two-stream flow in a thin plasma slab —A. V. Pashchenko and B. N. Rutkevich. 19(12), 1538–40 (Jun. 1975); CPM-7508X0412

Rut'kov, E. V.—Time dependence of ion currents produced through surface ionization. Ionization of Ba on the (111) face of iridium —É. Ya. Zandberg, E. V. Rut'kov, and A. Ya. Tontegode. 19(2), 261–3 (Aug. 1974); CPM-7408X1525

Ryabchikov, A. I.—Reflection of a high-current relativistic electron beam from a conducting surface —A. N. Didenko, A. I. Ryabchikov, V. A. Tuzov, and Yu. P. Usov. 19(12), 1625–6 (Jun. 1975); CPM-7508X0499

Ryabtsov, A. V.—Linear accelerator for beam injection into a slowly rising magnetic field —D. G. Borisov, A. I. Gryzlov, V. M. Levin, and A. V. Ryabtsov. 19(4), 509–10 (Oct. 1974); CPM-7412X0293

Rybin, P. P.—Two-section solenoid with internal "equally-loaded" section; power as a function of the length of the internal section —G. S. Veisig, A. P. Doroshenko, and P. P. Rybin. 19(3), 416–8 (Sep. 1974); CPM-7412X1102

Ryzhov, Ń. M.—Magnetodrift waves in a finite-β plasma —Ń. M. Ryzhov, V. L. Sizonenko, V. A. Suprunenko, E. A. Sukhomlin, and Yu. V. Gutarev. 19(6), 722–5 (Dec. 1974); CPM-7501X0722

S

Saenko, V. A.—Electron-beam excited crossed-field discharge —V. A. Saenko and M. M. Kasumov. 19(6), 759–61 (Dec. 1974); CPM-7501X0759

Safikhodzhaev, N. M.—Radiation from a charged particle moving close to an anisotropic dielectric —A. I. Plis and N. M. Safikhodzhaev. 19(7), 865–7 (Jan. 1975); CPM-7503X0753

Safonov, M. P.—Efficiency of the scattering of "unstable" charged particles in quadrupole mass spectrometers —É. P. Sheretov, B. I. Kolotilin, and M. P. Safonov. 19(12), 1622–4 (Jun. 1975); CPM-7508X0496

Sakharov, I. E.—Effect of plasma parameters on emission in an ion laser —I. E. Sakharov, V. V. Ermolin, and S. V. Shatalin. 19(8), 1081–4 (Feb. 1975); CPM-7504X1505

Salyadinov, V. S.—Optical characteristics of K-8 glass subject to radiation from a neodymium laser —A. M. Bonch-Bruevich, Ya. A. Imas, V. S. Salyadinov, and A. V. Shatilov. 19(2), 287–9 (Aug. 1974); CPM-7408X1551

Samoilenko, Yu. I.—Distributed systems for feedback control of a tokamak plasma —V. F. Gubarev and Yu. I. Samoilenko. 19(4), 463–7 (Oct. 1974); CPM-7412X0247

Samoilov, L. N.—Extraction of synchroton radiation from a cyclic electron accelerator with a strong magnetic field —V. I. Kvochka, V. S. Panasyuk, V. F. Romanovskii, L. N. Samoilov, A. A. Sokolov, B. M. Stepanov, and Yu. M. Tereshkin. 19(6), 762–6 (Dec. 1974); CPM-7501X0762

Sanochkin, Yu. V.—Low-pressure self-maintained discharge with suppressed electron drift. I —V. K. Kalashnikov and Yu. V. Sanochkin. 19(12), 1549–53 (Jun. 1975); CPM-7508X0423
—Low-pressure self-maintained discharge with suppressed electron drift. II —Yu. V. Sanochkin and V. K. Kalashnikov. 19(12), 1554–8 (Jun. 1975); CPM-7508X0428
Sapargaliev, A. A.—Theory of the cathode lens. III. Derivation of equations for composite cathode lenses —V. M. Kel'man, A. A. Sapargaliev, and E. M. Yakushev. 19(5), 592–6 (Nov. 1974); CPM-7501X0386
—Theory of the cathode lens. IV. Aberrations of composite cathode lens —V. M. Kel'man, A. A. Sapargaliev, and E. M. Yakushev. 19 (5), 597–9 (Nov. 1974); CPM-7501X0391
Savichev, A. T.—Dynamics and emission of coaxial plasma shells in air —A. F. Aleksandrov, V. V. Perebeinos, A. T. Savichev, and I. B. Timofeev. 19(1), 38–42 (Jul. 1974); CPM-7407X1550
—Initial stage of a high-current discharge in air —A. F. Aleksandrov, V. V. Perebeinos, A. T. Savichev, and I. B. Timofeev. 19(11), 1490–1 (May 1975); CPM-7506X1244
Savichev, V. V.—Effect of a high-current relativistic electron beam on a metal —B. I. Dmitrenko, L. V. Leskov, G. P. Maksimov, S. L. Nedoseev, V. V. Savichev, V. P. Smirnov, and A. M. Spektor. 19 (9), 1224–5 (Mar. 1975); CPM-7505X0646
Savin, V. V.—Characteristics of the electrical ionization CO$_2$ laser —Yu. I. Bychkov, Yu. A. Kurbatov, and V. V. Savin. 19(4), 506–8 (Oct. 1974); CPM-7412X0290
Savkin, V. Ya.—Formation of a narrow gas jet in vacuum —G. I. Dimov and V. Ya. Savkin. 19(6), 755–8 (Dec. 1974); CPM-7501X0755
Seleznev, V. G.—Method for determining the absolute characteristics of CF$_3$I laser emission —V. S. Komarov, V. G. Seleznev, and G. A. Skorobogatov. 19(4), 558–60 (Oct. 1974); CPM-7412X0342
—Absolute-photometry determination of the rate constant of the gas-phase reaction of the radical compound C$_3$F$_7$ and I(^{2}P$_{3/2}$) —G. A. Skorobogatov, V. S. Komarov, and V. G. Seleznev. 19(9), 1239–41 (Mar. 1975); CPM-7505X0661
Selin, L. N.—Contraction of the positive column of a glow discharge due to the presence of negative ions —L. A. Mikhalev and L. N. Selin. 19(5), 689–90 (Nov. 1974); CPM-7501X0483
Selyakov, V. I.—Multiple reflection of light in a shock tube —V. D. Mironov and V. I. Selyakov. 19(3), 402–4 (Sep. 1974); CPM-7412X1088
Semashko, N. N.—Production of an ion beam by a magnetic system with opposed fields —V. B. Glasko, A. G. Sveshnikov, and N. N. Semashko. 19(2), 201–5 (Aug. 1974); CPM-7408X1465
Semenov, I. N.—Pulsed neodymium–glass laser with periodic Q switching —T. A. Kuzovkova, E. V. Nilov, V. A. Rusov, I. N. Semenov, and A. A. Chertkov. 19(4), 503–5 (Oct. 1974); CPM-7412X0287
Semenov, V. V.—Diagnostics of a laser–produced plasma by a scattering method using an electron–optical image converter —E. A. Burunov, G. M. Malyshev, G. T. Razdobarin, and V. V. Semenov. 19(1), 66–9 (Jul. 1974); CPM-7407X1578
—Two–spin oscillator with optical orientation of electrons and nuclei —R. A. Zhitnikov and V. V. Semenov. 19(1), 105–9 (Jul. 1974); CPM-7407X1617
—Effect of instrumental noise on a system with two spin oscillators using Cs^{133} and He^3 —R. A. Zhitnikov, V. V. Semenov, and P. A. Klyushkin. 19(4), 556–7 (Oct. 1974); CPM-7412X0340
Serebryakov, V. A.—Interaction of intense laser radiation with solid targets —L. V. Dubovoi, V. D. Dyatlov, V. I. Kryzhanovskii, A. A. Mak, R. N. Medvedev, A. N. Popytaev, V. A. Serebryakov, V. N. Sizov, and A. D. Starikov. 19(11), 1477–9 (May 1975); CPM-7506X1231
Serezhkin, Yu. G.—Narrow–band decimeter radiation from lighting —E. L. Kosarev and Yu. G. Serezhkin. 19(2), 229–33 (Aug. 1974); CPM-7408X1493
Sergeev, A. A.—Plasma density in a magnetoplasma compressor —A. K. Vinogradova, V. P. Vinogradov, A. I. Morozov, and A. A. Sergeev. 19(3), 421–3 (Sep. 1974); CPM-7412X1107
Sergeev, A. V.—Aberrations in systems with plane and spherical detection apertures —V. V. Izokh, A. V. Sergeev, and I. Yu. Shmidov. 19(9), 1177–80 (Mar. 1975); CPM-7505X0599
Serikov, A. V.—Modulation of microwaves by density fluctuations in a plasma —L. A. Dushin, A. V. Serikov, A. I. Skibenko, E. V. Krivorukov, and I. P. Fomin. 19(9), 1163–7 (Mar. 1975); CPM-7505X0585
Serov, Yu. L.—Interferometer measurement of the neutral cesium distribution in a short low–voltage arc —Yu. L. Serov and I. P. Yavor. 19(6), 751–4 (Dec. 1974); CPM-7501X0751
—Atomic density in the low-voltage arc in a cesium diode —F. G. Baksht, A. A. Kostin, Yu. L. Serov, and I. P. Yavor. 19(11), 1424–5 (May 1975); CPM-7506X1178
Shabanov, O. M.—Behavior of molten salts in strong electric fields —A. Z. Éfendiev, O. M. Shabanov, S. M. Gadzhiev, and S. M. Tagirov. 19(6), 820–3 (Dec. 1974); CPM-7501X0820
Shaporenko, A. A.—Scattering of He$^+$ ions by the core of the He atom —Z. Z. Latypov and A. A. Shaporenko. 19(7), 976–7 (Jan. 1975); CPM-7503X0864
Shapovalov, A. S.—Shot noise in a thermionic cathode —A. F. Golubentsev and A. S. Shapovalov. 19(10), 1345–6 (Apr. 1975); CPM-7506X0279
Shaptala, V. G.—Second–harmonic generation and emission in wave conversion at a plasma boundary —A. N. Kondratenko, V. G. Shaptala, and V. M. Kuklin. 19(1), 22–4 (Jul. 1974); CPM-7407X1534
—Scattering of high–frequency electromagnetic waves by ion–acoustic oscillations in a bounded plasma —V. G. Shaptala. 19(2), 193–6 (Aug. 1974); CPM-7408X1457
Shatalin, S. V.—Effect of plasma parameters on emission in an ion laser —I. E. Sakharov, V. V. Ermolin, and S. V. Shatalin. 19(8), 1081–4 (Feb. 1975); CPM-7504X1505
Shatilov, A. V.—Optical characteristics of K–8 glass subject to radiation from a neodymium laser —A. M. Bonch–Bruevich, Ya. A. Imas, V. S. Salyadinov, and A. V. Shatilov. 19(2), 287–9 (Aug. 1974); CPM-7408X1551
Shcheglov, V. A.—Photochemical waves in a medium with a branch–chain conversion mechanism —A. N. Oraevskii, V. P. Pimenov, and V. A. Shcheglov. 19(6), 782–6 (Dec. 1974); CPM-7501X0782
—Gas polymerization wave excited by monochromatic light —A. I. Plis and V. A. Shcheglov. 19(9), 1262–3 (Mar. 1975); CPM-7505X0684
Shcherbakov, A. P.—Simulation of ion scattering on diatomic molecules —M. L. Aleksandrov, N. S. Pliss, and A. P. Shcherbakov. 19(3), 394–5 (Sep. 1974); CPM-7412X1080
Shcherbinin, O. N.—Role of collisions in plasma absorption of electromagnetic waves near the lower hybrid —B. V. Galaktionov, V. V. D'yachenko, M. M. Larionov, and O. N. Shcherbinin. 19(4), 459–62 (Oct. 1974); CPM-7412X0243
Shcherbinin, P. P.—Volt—ampere characteristic of the low-voltage arc. I. Recombination model —P. P. Shcherbinin. 19(11), 1436–41 (May 1975); CPM-7506X1190
Shchukin, E. R.—Thermophoresis and diffusophoresis of small, volatile aerosol particles —Yu. I. Yalamov and E. R. Shchukin. 19 (2), 278–9 (Aug. 1974); CPM-7408X1542
Shelepin, L. A.—Kinetics of gasdynamic lasers. Effect of nozzle geometry on inversion —A. S. Biryukov and L. A. Shelepin. 19(6), 775–81 (Dec. 1974); CPM-7501X0775
—Plasma dynamic lasers —S. A. Reshetnyak and L. A. Shelepin. 19 (8), 1076–80 (Feb. 1975); CPM-7504X1500
Shenderovich, A. M.—Self-acceleration of an intense electron beam —I. A. Grishaev, A. N. Dedik, V. V. Zakutin, I. I. Magda, Yu. V. Tkach, and A. M. Shenderovich. 19(8), 1087–9 (Feb. 1975); CPM-7504X1511
Shendrik, V. A.—Cerenkov instabilities of a relativistic beam in a periodic plasma–filled waveguide —V. I. Kurilko, Yu. V. Tkach, and V. A. Shendrik. 19(5), 607–11 (Nov. 1974); CPM-7501X0401
Sher, S. P.—Linear transient response of a fully ionized plasma in a pulsed electric field —V. V. Istomin, S. P. Sher, and S. P. Dovgopol. 19(7), 963–4 (Jan. 1975); CPM-7503X0851
Sheremet, V. I.—Shielding properties of superconducting shields —S. I. Bondarenko, S. S. Vinogradov, G. A. Gogadze, S. S. Perepelkin, and V. I. Sheremet. 19(6), 824–8 (Dec. 1974); CPM-7501X0824
—Superconducting magnetic shields —S. I. Bondarenko and V. I. Sheremet. 19(7), 952–5 (Jan. 1975); CPM-7503X0840
Sheretov, É. P.—Efficiency of the scattering of "unstable" charged particles in quadrupole mass spectrometers —É. P. Sheretov, B. I. Kolotilin, and M. P. Safonov. 19(12), 1622–4 (Jun. 1975); CPM-7508X0496
Shermergor, T. D.—Calculation of permittivity of an inhomogeneous dielectric by a variational method —G. A. Ermakov, A. G. Fokin, and T. D. Shermergor. 19(2), 157–60 (Aug. 1974); CPM-7408X1421

—Calculation of bounds for the effective permittivity of an inhomogeneous dielectric —G. A. Ermakov, A. G. Fokin, and T. D. Shermergor. 19(2), 161–5 (Aug. 1974); CPM-7408X1425

Shipilevskii, B. M.—Impurities and crystal dimensions in zone refining —V. G. Glebovskii and B. M. Shipilevskii. 19(9), 1231–5 (Mar. 1975); CPM-7505X0653

Shishkin, B. B.—Electron–microscope and x–ray study of thermionic emitters made from Mo–Pt alloys —B. B. Shishkin and R. S. Bakhtiyarov. 19(2), 243–50 (Aug. 1974); CPM-7408X1507

Shishkin, V. A.—Use of a field-emission microscope to measure the pressure of pump oil —V. Ya. Pliskovskii, M. S. Sukonnik, and V. A. Shishkin. 19(10), 1347–51 (Apr. 1975); CPM-7506X0281

Shmidov, I. Yu.—Aberrations in systems with plane and spherical detection apertures —V. V. Izokh, A. V. Sergeev, and I. Yu. Shmidov. 19(9), 1177–80 (Mar. 1975); CPM-7505X0599

Shneerson, G. A.—Distortion of single-turn solenoids in ultrahigh magnetic fields —G. A. Shneerson. 19(10), 1371–7 (Apr. 1975); CPM-7506X0305

Sholom, V. K.—Approximate similarity relations in the electrical explosions of underwater conductors —E. V. Krivitskii and V. K. Sholom. 19(6), 798–801 (Dec. 1974); CPM-7501X0798

—Electrical characteristics of underwater exploding wires —V. K. Sholom, E. V. Krivitskii, and V. P. Litvinenko. 19(10), 1329–31 (Apr. 1975); CPM-7506X0263

Shpenik, O. B.—Excitation collisions between magnesium ions and inert gas atoms —V. L. Ovchinnikov, O. B. Shpenik, and I. P. Zapesochnyi. 19(3), 382–4 (Sep. 1974); CPM-7412X1068

Shtepa, N. I.—Graphical methods for constructing trajectories of small particles in electrostatic fields —N. I. Shtepa. 19(9), 1253–5 (Mar. 1975); CPM-7505X0675

Shubin, A. F.—Transient thermionic-field emission from a point cathode —E. A. Litvinov and A. F. Shubin. 19(8), 1131–2 (Feb. 1975); CPM-7504X1555

Shubina, V. V.—Mass spectrum of secondary ions ejected from the surface of a single crystal of gallium arsenide by argon ions —A. G. Koval', V. V. Bobkov, Yu. A. Klimovskii, S. S. Strel'chenko, V. V. Shubina, V. V. Lebedev, and Ya. M. Fogel'. 19(12), 1587–9 (Jun. 1975); CPM-7508X0461

Shulaev, N. S.—Nonmonoenergetic relativistic electron beam in a bounded collisional plasma —V. P. Grigor'ev and N. S. Shulaev. 19(1), 20–1 (Jul. 1974); CPM-7407X1532

Shulika, N. G.—Conversion of neutral hydrogen into protons in dense plasmas —T. A. Bazilevskaya, L. I. Krupnik, and N. G. Shulika. 19(6), 741–4 (Dec. 1974); CPM-7501X0741

Shumskii, M. G.—Crystal defects of heterostructures of AlAs–GaAs solid solutions and effect on the characteristics of injection lasers —L. V. Druzhinina, V. T. Bublik, L. M. Dolginov, P. G. Eliseev, M. P. Kerbelev, V. B. Osvenskii, I. Z. Pinsker, and M. G. Shumskii. 19(7), 935–9 (Jan. 1975); CPM-7503X0823

Shuster, A. L.—Electromagnetic levitation of a liquid metal droplet with strong skin effect (surface shape and internal pressure) —A. N. Tverdokhlebov and A. L. Shuster. 19(11), 1399–402 (May 1975); CPM-7506X1153

—Liquid metal droplet with high surface tension in an axially-symmetric electromagnetic field (strong skin effect) —A. N. Tverdokhlebov and A. L. Shuster. 19(11), 1512–3 (May 1975); CPM-7506X1266

Shustova, N. V.—Generation of drift waves by an rf field near the lower hybrid frequency —Yu. F. Baranov, D. G. Bulyginskii, M. I. Vil'dzhyunas, B. V. Galaktionov, and N. V. Shustova. 19(6), 732–5 (Dec. 1974); CPM-7501X0732

Sidorovich, V. G.—Efficiency of light–beam conversion by dynamic three–dimensional phase holograms —D. I. Stasel'ko and V. G. Sidorovich. 19(3), 361–5 (Sep. 1974); CPM-7412X1047

—Transformation of light beams by dynamic correctors using three-dimensional displacement phase holograms —V. G. Sidorovich and D. I. Stasel'ko. 19(12), 1593–7 (Jun. 1975); CPM-7508X0467

Siksin, V. S.—Energy resolution of quadrupole lenses for charged–particle beams —V. S. Siksin. 19(3), 301–7 (Sep. 1974); CPM-7412X0987

Silin, V. P.—Anomalous ion heating in a parametrically unstable plasma —I. S. Baikov and V. P. Silin. 19(12), 1529–33 (Jun. 1975); CPM-7508X0403

Simonenko, L. S.—Gas focusing of a negative–ion beam —M. D. Gabovich, A. P. Naida, I. M. Protsenko, L. S. Simonenko, and I. A. Soloshenko. 19(4), 546–7 (Oct. 1974); CPM-7412X0330

Sinyavskii, V. V.—Optimum dimensions of a coaxial thermionic converter —V. V. Sinyavskii. 19(3), 373–7 (Sep. 1974); CPM-7412X1059

Sizonenko, V. L.—Kinetic plasma instabilities excited by a monoenergetic beam —A. I. Ranyuk and V. L. Sizonenko. 19(5), 628–9 (Nov. 1974); CPM-7501X0422

—Quasilinear theory of beam–generated surface waves in a plasma —V. I. Pakhomov and V. L. Sizonenko. 19(5), 630–4 (Nov. 1974); CPM-7501X0424

—Instabilities in a finite-β plasma with transverse current. I —A. I. Pyatak and V. L. Sizonenko. 19(5), 635–9 (Nov. 1974); CPM-7501X0429

—Instabilities in a finite-β plasma with transverse current. II —A. I. Pyatak and V. L. Sizonenko. 19(5), 640–4 (Nov. 1974); CPM-7501X0434

—Magnetodrift waves in a finite-β plasma —N. M. Ryzhov, V. L. Sizonenko, V. A. Suprunenko, E. A. Sukhomlin, and Yu. V. Gutarev. 19(6), 722–5 (Dec. 1974); CPM-7501X0722

—Transverse-current plasma instability —D. G. Lominadze and V. L. Sizonenko. 19(9), 1145–9 (Mar. 1975); CPM-7505X0567

—Plasma instability due to an anisotropic electron distribution —D. G. Lominadze and V. L. Sizonenko. 19(9), 1150–3 (Mar. 1975); CPM-7505X0572

—Turbulent plasma heating and the Buneman instability —V. L. Sizonenko. 19(9), 1260–1 (Mar. 1975); CPM-7505X0682

Sizov, V. N.—Interaction of intense laser radiation with solid targets —L. V. Dubovoi, V. D. Dyatlov, V. I. Kryzhanovskii, A. A. Mak, R. N. Medvedev, A. N. Popytaev, V. A. Serebryakov, V. N. Sizov, and A. D. Starikov. 19(11), 1477–9 (May 1975); CPM-7506X1231

Skachek, G. V.—Transmission of a high–current relativistic beam through a gas —Yu. V. Tkach, I. I. Magda, G. V. Skachek, S. S. Pushkarev, and I. P. Panchenko. 19(3), 412–3 (Sep. 1974); CPM-7412X1098

Skibenko, A. I.—Spatial characteristics and loss of plasma produced by an electron beam in a magnetic trap —M. Yu. Bredikhin, A. I. Maslov, A. I. Skibenko, E. I. Skibenko, I. P. Fomin, and V. B. Yuferov. 19(1), 49–52 (Jul. 1974); CPM-7407X1561

—Modulation of microwaves by density fluctuations in a plasma —L. A. Dushin, A. V. Serikov, A. I. Skibenko, E. V. Krivorukov, and I. P. Fomin. 19(9), 1163–7 (Mar. 1975); CPM-7505X0585

Skibenko, A. Y.—Plasma equilibrium and confinement in a poloidal heliotron configuration. II —V. G. Zykov, V. I. Karpukhin, Yu. F. Lonin, N. N. Podteregera, N. I. Rudnev, A. Y. Skibenko, V. T. Tolok, and I. P. Fomin. 19(8), 1069–72 (Feb. 1975); CPM-7504X1493

Skibenko, E. I.—Spatial characteristics and loss of plasma produced by an electron beam in a magnetic trap —M. Yu. Bredikhin, A. I. Maslov, A. I. Skibenko, E. I. Skibenko, I. P. Fomin, and V. B. Yuferov. 19(1), 49–52 (Jul. 1974); CPM-7407X1561

Sklyarov, M. Yu.—Thermal effect of continuous laser radiation on optically transparent media —N. S. Bardina, A. I. Portnyagin, M. Yu. Sklyarov, and A. A. Churin. 19(4), 491–4 (Oct. 1974); CPM-7412X0275

Skoblik, I. P.—Investigation of a plasma focus with a time-resolved laser interferometer —I. M. Zolototrubov, I. P. Skoblik, A. G. Tolstolutskii, and V. I. Privezentsev. 19(8), 1061–2 (Feb. 1975); CPM-7504X1485

Skoblik, M. N.—Magnetic topography of toroidal systems —M. N. Skoblik, V. E. Ziser, A. V. Georgievskii, and V. G. Peletminskaya. 19(10), 1277–80 (Apr. 1975); CPM-7506X0211

Skorobogatov, G. A.—Quenching in the CF_3I photodissociation laser —G. A. Skorobogatov, V. M. Tret'yak, and V. S. Komarov. 19(4), 495–8 (Oct. 1974); CPM-7412X0279

—Method for determining the absolute characteristics of CF_3I laser emission —V. S. Komarov, V. G. Seleznev, and G. A. Skorobogatov. 19(4), 558–60 (Oct. 1974); CPM-7412X0342

—Absolute-photometry determination of the rate constant of the gas-phase reaction of the radical compound C_3F_7 and $I(^2P_{3/2})$ —G. A. Skorobogatov, V. S. Komarov, and V. G. Seleznev. 19(9), 1239–41 (Mar. 1975); CPM-7505X0661

Skosyrev, Yu. V.—Anisotropic plasma heating near the lower hybrid frequency —V. M. Glagolev, V. V. Martynenko, and Yu. V. Skosyrev. 19(12), 1543–6 (Jun. 1975); CPM-7508X0417

Skripal', L. P.—Low pressure discharge with high–energy electrons —R. A. Demirkhanov, Yu. V. Kursanov, and L. P. Skripal'. 19(7), 891–4 (Jan. 1975); CPM-7503X0779

Skripnik, V. G.—Skin effect in a constant magnetic field —Z. K. Yankauskas, V. I. Chesonis, and V. G. Skripnik. 19(9), 1251–2 (Mar. 1975); CPM-7505X0673

Skvortsov, V. V.—Hot probe measurements in a rarefied streaming plasma —E. M. Netsvetailov, L. V. Nosachev, and V. V. Skvortsov. 19(12), 1579–83 (Jun. 1975); CPM-7508X0453

Slobodenyuk, G. I.—Line shape of a quadrupole mass spectrometer —G. I. Slobodenyuk. 19(2), 292–3 (Aug. 1974); CPM-7408X1556

Smetanin, V. I.—Streamer propagation after the voltage termination in a streamer chamber —N. S. Rudenko and V. I. Smetanin. 19 (12), 1616–7 (Jun. 1975); CPM-7508X0490

Smirnov, G. V.—Electrical breakdown of vacuum gaps under superhigh voltage pulses —I. I. Kalyatskii, G. M. Kassirov, and G. V. Smirnov. 19(11), 1434–5 (May 1975); CPM-7506X1188

Smirnov, L. A.—X-ray fluorescence of oxygen in H_2O —L. A. Smirnov. 19(5), 702 (Nov. 1974); CPM-7501X0496

Smirnov, V. P.—Switching characteristis of a discharge in water —V. M. Kuleshov, S. L. Nedoseev, V. P. Smirnov, and A. M. Spektor. 19(1), 150–1 (Jul. 1974); CPM-7407X1662

—Effect of a high-current relativistic electron beam on a metal —B. I. Dmitrenko, L. V. Leskov, G. P. Maksimov, S. L. Nedoseev, V. V. Savichev, V. P. Smirnov, and A. M. Spektor. 19(9), 1224–5 (Mar. 1975); CPM-7505X0646

Sobenin, N. P.—Control of output energy in linear electron accelerators —V. N. Golovin and N. P. Sobenin. 19(7), 932–4 (Jan. 1975); CPM-7503X0820

Sobolev, S. S.—Acceleration of plasma electrons in strong electric fields —Z. A. Al'bikov, M. I. Ivanov, V. I. Kazacha, O. V. Kozlov, V. D. Rusanov, and S. S. Sobolev. 19(11), 1498–9 (May 1975); CPM-7506X1252

Sokolov, A. A.—Extraction of synchroton radiation from a cyclic electron accelerator with a strong magnetic field —V. I. Kvochka, V. S. Panasyuk, V. F. Romanovskii, L. N. Samoilov, A. A. Sokolov, B. M. Stepanov, and Yu. M. Tereshkin. 19(6), 762–6 (Dec. 1974); CPM-7501X0762

Sokolov, V. A.—Nonlinear polarizability of a gaseous medium in a longitudinal magnetic field —V. A. Sokolov and L. M. Khayutin. 19(5), 589–91 (Nov. 1974); CPM-7501X0383

Sokolov, V. F.—Radial distribution of density and potential in a glow discharge in CO_2 and water —A. I. Maksimov and V. F. Sokolov. 19(10), 1359–61 (Apr. 1975); CPM-7506X0293

Solntsev, G. S.—Effect of ion current on the measurement of the electron energy distribution function by the second-derivative method —V. A. Dovzhenko, A. P. Ershov, and G. S. Solntsev. 19 (4), 538–9 (Oct. 1974); CPM-7412X0322

Solnyshkov, A. I.—Aberrations in a straight ion-optical accelerator —E. I. Gerasimov, A. I. Solnyshkov, and G. V. Tarvid. 19(1), 131–3 (Jul. 1974); CPM-7407X1643

Solodovchenko, S. I.—Electron temperature in a high-frequency helium discharge —V. S. Voitsenya, A. Yu. Voloshko, V. G. Konovalov, and S. I. Solodovchenko. 19(7), 909–10 (Jan. 1975); CPM-7503X0797

Solodovnikov, A. P.—Dielectric strength of a vacuum gap with electrodes irradiated with He^+ and H^+ ions —A. P. Solodovnikov and Yu. M. Khirnyi. 19(8), 1122 (Feb. 1975); CPM-7504X1546

Solonitsyn, B. P.—Steady-state study of the temperature dependence of the mutual-diffusion coefficients of certain gases —N. D. Kosov and B. P. Solonitsyn. 19(4), 541–2 (Oct. 1974); CPM-7412X0325

Soloshenko, I. A.—Gas focusing of a negative-ion beam —M. D. Gabovich, A. P. Naida, I. M. Protsenko, L. S. Simonenko, and I. A. Soloshenko. 19(4), 546–7 (Oct. 1974); CPM-7412X0330

—Instabilities in interpenetrating electron and ion beams —I. A. Soloshenko and L. P. Katsubo. 19(10), 1317–20 (Apr. 1975); CPM-7506X0251

—Measurement of ion density by the dispersion relation for an ion-beam plasma —M. D. Gabovich, L. P. Katsubo, and I. A. Soloshenko. 19(11), 1412–3 (May 1975); CPM-7506X1166

Sominskii, G. G.—End current in a magnetron with a secondary-emission cathode —G. G. Sominskii, S. A. Fridrikhov, O. Yu. Tsybin, and A. P. Karizhskii. 19(3), 378–81 (Sep. 1974); CPM-7412X1064

—Evaluation of charge distribution in a crossed-field device from ion bombardment of the cathode —V. I. Malyugin and G. G. Sominskii. 19(7), 942–5 (Jan. 1975); CPM-7503X0830

Soms, L. N.—Polarization of a cavity with a thermally deformed active element —I. B. Vitrishchak, L. N. Soms, and A. A. Tarasov. 19(5), 664–8 (Nov. 1974); CPM-7501X0458

Sorokin, Yu. M.—Multimode parametric interactions in a plasma with low-frequency pumping —Yu. M. Sorokin and N. S. Stepanov. 19(2), 185–9 (Aug. 1974); CPM-7408X1449

Sotnikov, V. I.—Method for optical modulation of an electron beam —V. I. Sotnikov. 19(11), 1510–1 (May 1975); CPM-7506X1264

Spektor, A. M.—Switching characteristis of a discharge in water —V. M. Kuleshov, S. L. Nedoseev, V. P. Smirnov, and A. M. Spektor. 19(1), 150–1 (Jul. 1974); CPM-7407X1662

—Effect of a high-current relativistic electron beam on a metal —B. I. Dmitrenko, L. V. Leskov, G. P. Maksimov, S. L. Nedoseev, V. V. Savichev, V. P. Smirnov, and A. M. Spektor. 19(9), 1224–5 (Mar. 1975); CPM-7505X0646

Stakhanov, I. P.—Stability of ball lightning —I. P. Stakhanov. 19(7), 861–4 (Jan. 1975); CPM-7503X0749

—Analytic model of the cesium arc —V. P. Pashchenko, V. L. Mironovich, and I. P. Stakhanov. 19(10), 1332–6 (Apr. 1975); CPM-7506X0266

Starikov, A. D.—Interaction of intense laser radiation with solid targets —L. V. Dubovoi, V. D. Dyatlov, V. I. Kryzhanovskii, A. A. Mak, R. N. Medvedev, A. N. Popytaev, V. A. Serebryakov, V. N. Sizov, and A. D. Starikov. 19(11), 1477–9 (May 1975); CPM-7506X1231

Starodub, A. N.—Surface waves in a magnetized plasma in a radio-frequency field —E. E. Lovetskii and A. N. Starodub. 19(3), 319–22 (Sep. 1974); CPM-7412X1005

Stasel'ko, D. I.—Efficiency of light-beam conversion by dynamic three-dimensional phase holograms —D. I. Stasel'ko and V. G. Sidorovich. 19(3), 361–5 (Sep. 1974); CPM-7412X1047

—Transformation of light beams by dynamic correctors using three-dimensional displacement phase holograms —V. G. Sidorovich and D. I. Stasel'ko. 19(12), 1593–7 (Jun. 1975); CPM-7508X0467

Stefanovskaya, E. M.—Thermionic emission properties of zirconium, hafnium, and titanium nitrides in cesium vapor —M. A. Eremeev, V. S. Neshpor, A. B. Novikov, E. M. Stefanovskaya, and V. P. Fedorinov. 19(10), 1337–41 (Apr. 1975); CPM-7506X0271

Stepanov, B. M.—Extraction of synchroton radiation from a cyclic electron accelerator with a strong magnetic field —V. I. Kvochka, V. S. Panasyuk, V. F. Romanovskii, L. N. Samoilov, A. A. Sokolov, B. M. Stepanov, and Yu. M. Tereshkin. 19(6), 762–6 (Dec. 1974); CPM-7501X0762

—Electron lifetimes in atmosphere at high pressure —V. N. Kapinos, Yu. A. Medvedev, N. N. Morozov, and B. M. Stepanov. 19(11), 1507 (May 1975); CPM-7506X1261

Stepanov, K. N.—Parametric plasma instabilities excited by the sudden application of an electric field —A. B. Kitsenko and K. N. Stepanov. 19(1), 127–8 (Jul. 1974); CPM-7407X1639

—Excitation of electromagnetic ion cyclotron waves by fast ions —T. D. Kaladze, D. G. Lominadze, and K. N. Stepanov. 19(2), 175–6 (Aug. 1974); CPM-7408X1439

—Nonlinear behavior of monochromatic surface waves excited by a beam —A. B. Kitsenko, I. M. Pankratov, and K. N. Stepanov. 19 (11), 1505–6 (May 1975); CPM-7506X1259

Stepanov, N. S.—Multimode parametric interactions in a plasma with low-frequency pumping —Yu. M. Sorokin and N. S. Stepanov. 19 (2), 185–9 (Aug. 1974); CPM-7408X1449

Stolovich, N. N.—Simplified model for the initial stage of exploding wire phenomena —N. N. Stolovich, V. G. Maksimov, and N. S. Minitskaya. 19(10), 1321–8 (Apr. 1975); CPM-7506X0255

Strel'chenko, S. S.—Mass spectrum of secondary ions ejected from the surface of a single crystal of gallium arsenide by argon ions —A. G. Koval', V. V. Bobkov, Yu. A. Klimovskii, S. S. Strel'chenko, V. V. Shubina, V. V. Lebedev, and Ya. M. Fogel'. 19(12), 1587–9 (Jun. 1975); CPM-7508X0461

Sudarushkin, A. S.—Proton extraction from the 70-GeV accelerator for the Ludmila liquid-hydrogen chamber (extraction system S) —A. A. Aseev, A. I. Drozhdin, B. A. Zelenov, É. A. Merker, L. L. Moizhes, K. P. Myznikov, A. A. Roshchin, V. M. Tatarenko, M. A. Kholodenko, A. D. Artemov, L. N. Vaulin, V. I. Gordin, I. I. Kovalevskii, V. N. Rozhkov, M. M. Suvorov, A. S. Sudarushkin, and V. I. Chuiko. 19(1), 70–6 (Jul. 1974); CPM-7407X1582

Suetin, P. E.—Temperature dependence of trace diffusion coefficients of certain gases —A. É. Loiko, B. A. Ivakin, and P. E. Suetin. 19 (3), 434 (Sep. 1974); CPM-7412X1120

—Use of the distribution function to describe free molecular beams —I. G. Neudachin, B. T. Porodnov, and P. E. Suetin. 19(4), 511–4 (Oct. 1974); CPM-7412X0295

—Flow of low-density gases in a capillary grid —B. T. Porodnov, V. D. Akin'shin, V. I. Kichaev, S. F. Borisov, and P. E. Suetin. 19(4), 515–8 (Oct. 1974); CPM-7412X0299

—Diffusion and solubility of helium in potassium chloride —A. Ya. Kupryazhkin, P. V. Volobuev, and P. E. Suetin. 19(8), 1105–7 (Feb. 1975); CPM-7504X1529

Sukhanovskii, Yu. P.—Radiation yield of ions in liquid dielectrics as a function of temperature and radiation energy —V. I. Ivanov, E. D. Kleshchenko, Yu. P. Sukhanovskii, and V. V. Frolov. 19(11), 1468–70 (May 1975); CPM-7506X1222

Sukharev, M. V.—Reversibility of chalcogenide materials in holography —S. B. Gurevich, N. N. Il'yashenko, B. T. Kolomiets, V. M. Lyubin, and M. V. Sukharev. 19(1), 152–3 (Jul. 1974); CPM-7407X1664

Sukhomlin, E. A.—Magnetodrift waves in a finite-β plasma —Ň. M. Ryzhov, V. L. Sizonenko, V. A. Suprunenko, E. A. Sukhomlin, and Yu. V. Gutarev. 19(6), 722–5 (Dec. 1974); CPM-7501X0722

Sukhorukov, A. P.—Nonlinear spherical aberrations and thermoelastic stresses in thermal self-focusing —A. A. Vigasin, Yu. A. Gorokhov, A. P. Sukhorukov, and A. M. Khachatryan. 19(5), 673–5 (Nov. 1974); CPM-7501X0467

Sukhovskii, E. S.—Parametric interaction of a charged particle beam with a periodic system —V. I. Koroza and E. S. Sukhovskii. 19(8), 1020–4 (Feb. 1975); CPM-7504X1444

Sukiasyan, É. A.—Electron density in an argon afterglow —O. P. Bochkova, R. I. Lyagushchenko, É. A. Sukiasyan, and Yu. A. Tolmachev. 19(4), 475–7 (Oct. 1974); CPM-7412X0259

Sukonnik, M. S.—Use of a field-emission microscope to measure the pressure of pump oil —V. Ya. Pliskovskii, M. S. Sukonnik, and V. A. Shishkin. 19(10), 1347–51 (Apr. 1975); CPM-7506X0281

Suladze, K. V.—Pulsed ion beams from a high-current plasma diode —B. A. Tskhadaya, A. A. Plyutto, and K. V. Suladze. 19(8), 1108–9 (Feb. 1975); CPM-7504X1532

Sultanov, M. A.—Supersonic plasma jet from a high-power pulsed discharge —M. A. Sultanov. 19(4), 478–82 (Oct. 1974); CPM-7412X0262

Sumin, L. V.—Kinetic energy of ions produced by surface ionization. I. Distribution over the velocity components —L. V. Sumin. 19(9), 1205–9 (Mar. 1975); CPM-7505X0627

Suprunenko, V. A.—Magnetodrift waves in a finite-β plasma —Ň. M. Ryzhov, V. L. Sizonenko, V. A. Suprunenko, E. A. Sukhomlin, and Yu. V. Gutarev. 19(6), 722–5 (Dec. 1974); CPM-7501X0722

Suvorov, M. M.—Proton extraction from the 70-GeV accelerator for the Ludmila liquid-hydrogen chamber (extraction system S) —A. A. Aseev, A. I. Drozhdin, B. A. Zelenov, É. A. Merker, L. L. Moizhes, K. P. Myznikov, A. A. Roshchin, V. M. Tatarenko, M. A. Kholodenko, A. D. Artemov, L. N. Vaulin, V. I. Gordin, I. I. Kovalevskii, V. N. Rozhkov, M. M. Suvorov, A. S. Sudarushkin, and V. I. Chuiko. 19(1), 70–6 (Jul. 1974); CPM-7407X1582

Sveshnikov, A. G.—Production of an ion beam by a magnetic system with opposed fields —V. B. Glasko, A. G. Sveshnikov, and N. N. Semashko. 19(2), 201–5 (Aug. 1974); CPM-7408X1465

Svettsov, V. I.—Electron energy distribution and electrical characteristics of the positive column in H_2 and H_2+Cl_2 —V. V. Zaitsev, A. I. Maksimov, and V. I. Svettsov. 19(1), 57–9 (Jul. 1974); CPM-7407X1569

Svin'in, M. P.—Beam focusing in an accelerator with inductive energy storage —V. A. Glukhikh, O. A. Gusev, E. G. Komar, V. S. Kuznetsov, M. P. Svin'in, and R. P. Fidel'skaya. 19(3), 366–7 (Sep. 1974); CPM-7412X1052

—High-current pulsed electron accelerator with an annular beam —M. I. Avramenko, V. A. Glukhikh, O. A. Gusev, E. G. Komar, O. L. Komarov, V. S. Kuznetsov, A. S. Perlin, and M. P. Svin'in. 19 (3), 368–70 (Sep. 1974); CPM-7412X1054

—Inductive energy storage in pulsed accelerators —V. A. Glukhikh, O. A. Gusev, E. G. Komar, and M. P. Svin'in. 19(5), 660–1 (Nov. 1974); CPM-7501X0454

T

Tagirov, S. M.—Behavior of molten salts in strong electric fields —A. Z. Éfendiev, O. M. Shabanov, S. M. Gadzhiev, and S. M. Tagirov. 19(6), 820–3 (Dec. 1974); CPM-7501X0820

Takibaev, Zh. S.—Charge-carrier density of the plasma produced in a Penning mixture by irradiation by uranium fission fragments and reactor radiation —G. A. Batyrbekov, Yu. D. Kuznetsov, and Zh. S. Takibaev. 19(5), 645–6 (Nov. 1974); CPM-7501X0439

Taranov, V. B.—Symmetry of high-frequency plasma motions —A. A. Zhmudskii and V. B. Taranov. 19(6), 717–8 (Dec. 1974); CPM-7501X0717

Tarasenko, V. F.—Infrared nitrogen laser using a transverse discharge —V. F. Tarasenko and Yu. I. Bychkov. 19(5), 693 (Nov. 1974); CPM-7501X0487

Tarasov, A. A.—Polarization of a cavity with a thermally deformed active element —I. B. Vitrishchak, L. N. Soms, and A. A. Tarasov. 19(5), 664–8 (Nov. 1974); CPM-7501X0458

Tarasov, V. F.—Angular aberration corrector in a cylindrical mirror analyzer —V. V. Zashkavara and V. F. Tarasov. 19(6), 841–2 (Dec. 1974); CPM-7501X0841

Tarasova, L. V.—Fast electrons and x rays from nanosecond gas discharges at 0.1–760 torr —L. V. Tarasova, L. N. Khudyakova, T. V. Loiko, and V. A. Tsukerman. 19(3), 351–3 (Sep. 1974); CPM-7412X1037

Tarvid, G. V.—Aberrations in a straight ion-optical accelerator —E. I. Gerasimov, A. I. Solnyshkov, and G. V. Tarvid. 19(1), 131–3 (Jul. 1974); CPM-7407X1643

Tatarenko, V. M.—Proton extraction from the 70-GeV accelerator for the Ludmila liquid-hydrogen chamber (extraction system S) —A. A. Aseev, A. I. Drozhdin, B. A. Zelenov, É. A. Merker, L. L. Moizhes, K. P. Myznikov, A. A. Roshchin, V. M. Tatarenko, M. A. Kholodenko, A. D. Artemov, L. N. Vaulin, V. I. Gordin, I. I. Kovalevskii, V. N. Rozhkov, M. M. Suvorov, A. S. Sudarushkin, and V. I. Chuiko. 19(1), 70–6 (Jul. 1974); CPM-7407X1582

Tel'kovskii, V. G.—Energy spectra of scattered particles in proton bombardment of a metal target —G. I. Zhabrev, V. A. Kurnaev, and V. G. Tel'kovskii. 19(7), 978–9 (Jan. 1975); CPM-7503X0866

Terekhin, D. K.—Frequency locking in a 3.39μ laser —E. Yu. Andreeva, S. N. Gulyaev, and D. K. Terekhin. 19(12), 1620–1 (Jun. 1975); CPM-7508X0494

Tereshkin, Yu. M.—Extraction of synchroton radiation from a cyclic electron accelerator with a strong magnetic field —V. I. Kvochka, V. S. Panasyuk, V. F. Romanovskii, L. N. Samoilov, A. A. Sokolov, B. M. Stepanov, and Yu. M. Tereshkin. 19(6), 762–6 (Dec. 1974); CPM-7501X0762

Testov, V. G.—Experimental investigation of microwave radiation produced by hypersonic flows —V. A. Lyutomskii, V. M. Polyakov, and V. G. Testov. 19(4), 483–5 (Oct. 1974); CPM-7412X0267

—N_2O-N_2-He gasdynamic laser —Yu. I. Grin' and V. G. Testov. 19 (7), 975 (Jan. 1975); CPM-7503X0863

Timofeev, A. V.—Drift instability in a weakly ionized plasma —S. V. Putvinskii and A. V. Timofeev. 19(10), 1295–9 (Apr. 1975); CPM-7506X0229

Timofeev, I. B.—Dynamics and emission of coaxial plasma shells in air —A. F. Aleksandrov, V. V. Perebeinos, A. T. Savichev, and I. B. Timofeev. 19(1), 38–42 (Jul. 1974); CPM-7407X1550

—Initial stage of a high-current discharge in air —A. F. Aleksandrov, V. V. Perebeinos, A. T. Savichev, and I. B. Timofeev. 19(11), 1490–1 (May 1975); CPM-7506X1244

Timofeev, M. N.—Electron energy spectrum in a high-current vacuum diode —S. P. Bugaev, V. I. Koshelev, and M. N. Timofeev. 19(9), 1193–5 (Mar. 1975); CPM-7505X0615

Timofeev, V. P.—Peak current in a cold-cathode magnetron —I. M. Vigdorchik and V. P. Timofeev. 19(1), 142–3 (Jul. 1974); CPM-7407X1654

Timonin, A. M.—Laser-initiated vacuum discharge —V. P. Kovalenko, A. A. Makarevich, V. A. Rodichkin, and A. M. Timonin. 19(11), 1429–31 (May 1975); CPM-7506X1183

Timoshenko, A. F.—Low-frequency oscillations in counter-streaming high-current electron beams —A. F. Timoshenko, D. V. Iremashvili, and Yu. K. Udovichenko. 19(8), 1038–41 (Feb. 1975); CPM-7504X1462

Timoshenko, A. P.—Wave excitation at half the gyrofrequency in counterstreaming electron beams —A. P. Timoshenko, D. V. Iremashvili, and Yu. K. Udovichenko. 19(12), 1584–6 (Jun. 1975); CPM-7508X0458

Tishchenko, V. A.—Investigation of ionization processes behind strong shock waves using an electrical conductivity probe —V. A. Tishchenko, N. V. Khandurov, and É. K. Chekalin. 19(5), 651–3 (Nov. 1974); CPM-7501X0445

Tkach, Yu. V.—Transmission of a high-current relativistic beam through a gas —Yu. V. Tkach, I. I. Magda, G. V. Skachek, S. S. Pushkarev, and I. P. Panchenko. 19(3), 412–3 (Sep. 1974); CPM-7412X1098

—Cerenkov instabilities of a relativistic beam in a periodic plasma-filled waveguide —V. I. Kurilko, Yu. V. Tkach, and V. A. Shendrik. 19(5), 607–11 (Nov. 1974); CPM-7501X0401

—Self-acceleration of an intense electron beam —I. A. Grishaev, A. N. Dedik, V. V. Zakutin, I. I. Magda, Yu. V. Tkach, and A. M. Shenderovich. 19(8), 1087–9 (Feb. 1975); CPM-7504X1511

Tkachuk, A. M.—Frequency-doubling single-mode laser for picosecond pulses —A. M. Bonch-Bruevich, A. M. Tkachuk, and A. A. Fedorov. 19(4), 549–51 (Oct. 1974); CPM-7412X0333

Tokarev, L. G.—Vacuum-UV and soft x-ray emission in a magnetoplasma compressor —P. E. Kovrov and L. G. Tokarev. 19 (4), 563–4 (Oct. 1974); CPM-7412X0347

Tolmachev, G. N.—Effect of the radiation density on ion drift velocity in a cadmium-helium laser —G. N. Tolmachev, E. L. Latush, and V. S. Mikhalevskii. 19(8), 1120–1 (Feb. 1975); CPM-7504X1544

Tolmachev, Yu. A.—Electron density in an argon afterglow —O. P. Bochkova, R. I. Lyagushchenko, É. A. Sukiasyan, and Yu. A. Tolmachev. 19(4), 475–7 (Oct. 1974); CPM-7412X0259

Tolok, V. T.—Plasma equilibrium and confinement in a poloidal heliotron configuration. I —V. G. Zykov, V. I. Karpukhin, Yu. F. Lonin, N. N. Podteregera, I. N. Rudnev, and V. T. Tolok. 19(8), 1063–8 (Feb. 1975); CPM-7504X1487

—Plasma equilibrium and confinement in a poloidal heliotron configuration. II —V. G. Zykov, V. I. Karpukhin, Yu. F. Lonin, N. N. Podteregera, I. N. Rudnev, A. Y. Skibenko, V. T. Tolok, and I. P. Fomin. 19(8), 1069–72 (Feb. 1975); CPM-7504X1493

Tolstoi, N. A.—Strobe unit for measuring luminescence in the range 10^{-7}–$2\cdot10^{-10}$ sec —V. A. Bonch-Bruevich and N. A. Tolstoi. 19(2), 284–6 (Aug. 1974); CPM-7408X1548

Tolstolutskii, A. G.—Investigation of a plasma focus with a time-resolved laser interferometer —I. M. Zolototrubov, I. P. Skoblik, A. G. Tolstolutskii, and V. I. Privezentsev. 19(8), 1061–2 (Feb. 1975); CPM-7504X1485

Tolstoluzhskii, A. P.—Conversion of regular charge-density waves in a inhomogeneous plasma —S. S. Kalmykova and A. P. Tolstoluzhskii. 19(4), 455–8 (Oct. 1974); CPM-7412X0239

—Launching and propagation of regular nonlinear waves in an anisotropic plasma-filled waveguide —V. I. Kurilko, A. P. Tols-toluzhskii, and Ya. B. Fainberg. 19(5), 622–7 (Nov. 1974); CPM-7501X0416

—Solitary waves in anisotropic plasma waveguide —V. I. Kurilko and A. P. Tolstoluzhskii. 19(7), 887–90 (Jan. 1975); CPM-7503X0775

Tonkopryad, V. M.—Hydrodynamic stability of the Uragan stellarator —V. M. Zalkind, Yu. K. Kuznetsov, V. K. Pashnev, and V. M. Tonkopryad. 19(8), 1123–5 (Feb. 1975); CPM-7504X1547

Tontegode, A. Ya.—Time dependence of ion currents produced through surface ionization. Ionization of Ba on the (111) face of iridium —É. Ya. Zandberg, E. V. Rut'kov, and A. Ya. Tontegode. 19(2), 261–3 (Aug. 1974); CPM-7408X1525

Torchinskii, V. M.—Electron energy distribution in helium, nitrogen, and their mixtures —K. D. Asvadurov, I. A. Vasil'eva, and V. M. Torchinskii. 19(3), 354–7 (Sep. 1974); CPM-7412X1040

Tret'yak, V. M.—Quenching in the CF_3I photodissociation laser —G. A. Skorobogatov, V. M. Tret'yak, and V. S. Komarov. 19(4), 495–8 (Oct. 1974); CPM-7412X0279

Trifonov, Yu. M.—Secondary-electron energy in a resonance discharge in a three-electrode system —Yu. A. Kulikov, V. V. Ogienko, and Yu. M. Trifonov. 19(8), 1090–2 (Feb. 1975); CPM-7504X1514

Tripol'nikov, V. P.—Radar sounding of sea ice —V. V. Bogorodskii and V. P. Tripol'nikov. 19(3), 414–5 (Sep. 1974); CPM-7412X1100

—Differential electromagnetic characteristics at the interface between ice and water in the ocean —V. V. Bogorodskii and V. P. Tripol'nikov. 19(4), 526–8 (Oct. 1974); CPM-7412X0310

Troitskii, S. V.—Scattering by ion-acoustic waves in a rectangular waveguide —S. V. Troitskii. 19(2), 181–4 (Aug. 1974); CPM-7408X1445

Troyan, P. E.—Thermal conditions for a sandwich cold cathode —F. M. Benson, P. E. Troyan, and Yu. B. Yankelevich. 19(7), 946–7 (Jan. 1975); CPM-7503X0834

Trubnikov, G. I.—Maximum current of a beam with finite phase volume —G. I. Trubnikov and V. S. Kuznetsov. 19(6), 715–6 (Dec. 1974); CPM-7501X0715

Tsapkov, V. I.—Resistance and enthalpy of refractory exploding wires —M. M. Martynyuk, I. Karimkhodzhaev, and V. I. Tsapkov. 19(11), 1458–61 (May 1975); CPM-7506X1212

Tsendin, L. D.—Propagation and stability of large amplitude ionization waves —M. S. Gorelik and L. D. Tsendin. 19(7), 880–2 (Jan. 1975); CPM-7503X0768

Tskhadaya, B. A.—Pulsed ion beams from a high-current plasma diode —B. A. Tskhadaya, A. A. Plyutto, and K. V. Suladze. 19(8), 1108–9 (Feb. 1975); CPM-7504X1532

Tskhakaya, D. D.—Low-frequency helical instability in a high-frequency electric field —V. S. Paverman and D. D. Tskhakaya. 19(11), 1508–9 (May 1975); CPM-7506X1262

Tskhakya, D. D.—Parametric excitation of helicon waves in a plasma by modulated radio frequency waves —V. S. Paverman and D. D. Tskhakya. 19(12), 1629–30 (Jun. 1975); CPM-7508X0503

Tsukerman, V. A.—Fast electrons and x rays from nanosecond gas discharges at 0.1–760 torr —L. V. Tarasova, L. N. Khudyakova, T. V. Loiko, and V. A. Tsukerman. 19(3), 351–3 (Sep. 1974); CPM-7412X1037

Tsukerman, V. G.—Multiple recording and erasure of optical information in certain glassy chalcogenides —V. V. Korsakov, V. I. Nalivaiko, V. G. Remesnik, and V. G. Tsukerman. 19(4), 565–6 (Oct. 1974); CPM-7412X0349

Tsvetkova, L. B.—A useful function in the thermodynamics of irreversible processes —A. V. Pamfilov, A. I. Lopushanskaya, and L. B. Tsvetkova. 19(4), 535–7 (Oct. 1974); CPM-7412X0319

Tsybin, A. M.—Solution of the Stefan problem —A. M. Tsybin. 19 (11), 1514–5 (May 1975); CPM-7506X1268

Tsybin, O. Yu.—End current in a magnetron with a secondary-emission cathode —G. G. Sominskii, S. A. Fridrikhov, O. Yu. Tsybin, and A. P. Karizhskii. 19(3), 378–81 (Sep. 1974); CPM-7412X1064

Tsyplenko, A. P.—Dielectric breakdown of detonation products —V. L. Korol'kov, M. A. Mel'nikov, and A. P. Tsyplenko. 19(12), 1569–70 (Jun. 1975); CPM-7508X0443

Tsytovich, V. N.—Linear theory for the low-frequency electromagnetic properties of an isotropic turbulent plasma —K. Komilov, F. Kh. Khakimov, and V. N. Tsytovich. 19(5), 615–7 (Nov. 1974); CPM-7501X0409

—Nonlinear statistical theory for condensation of Langmuir plasmons. III. Energy flux for plasma turbulence —F. Kh. Khakimov and V. N. Tsytovich. 19(10), 1300–2 (Apr. 1975); CPM-7506X0234

Tunkin, V. G.—Direct and cascade four-photon parametric scattering of light in $LiIO_3$ crystals —S. M. Arakelyan, V. G. Tunkin, A. I. Kholodnykh, and A. S. Chirkin. 19(6), 787–92 (Dec. 1974); CPM-7501X0787

Tuzov, V. A.—Reflection of a high-current relativistic electron beam from a conducting surface —A. N. Didenko, A. I. Ryabchikov, V. A. Tuzov, and Yu. P. Usov. 19(12), 1625–6 (Jun. 1975); CPM-7508X0499

Tverdokhlebov, A. N.—Electromagnetic levitation of a liquid metal droplet with strong skin effect (surface shape and internal pressure) —A. N. Tverdokhlebov and A. L. Shuster. 19(11), 1399–402 (May 1975); CPM-7506X1153

—Liquid metal droplet with high surface tension in an axially-symmetric electromagnetic field (strong skin effect) —A. N. Tverdokhlebov and A. L. Shuster. 19(11), 1512–3 (May 1975); CPM-7506X1266

Tyrnov, V. F.—Parametric instability of a spatially moderated electron beam in a magnetic field —N. S. Repalov and V. F. Tyrnov. 19(7), 871–3 (Jan. 1975); CPM-7503X0759

U

Udovichenko, Yu. K.—Low-frequency oscillations in counter-streaming high-current electron beams —A. F. Timoshenko, D. V. Iremashvili, and Yu. K. Udovichenko. 19(8), 1038–41 (Feb. 1975); CPM-7504X1462

—Wave excitation at half the gyrofrequency in counterstreaming electron beams —A. P. Timoshenko, D. V. Iremashvili, and Yu. K. Udovichenko. 19(12), 1584–6 (Jun. 1975); CPM-7508X0458

Udris, Ya. Ya.—Effect of electron reflection on the voltage-current characteristics of a high-voltage, hollow-cathode, glow discharge —Ya. Ya. Udris, V. A. Chernov, and L. G. Guseva. 19(1), 134–5 (Jul. 1974); CPM-7407X1646

Ukolov, A. S.—Radiation emitted by charged particles trapped by plane electromagnetic waves —V. Ya. Davydovskii and A. S. Ukolov. 19(8), 1057–60 (Feb. 1975); CPM-7504X1481

—Energy of charged particles accelerated by electromagnetic waves in a plasma with a spatially decreasing density —V. Ya. Davydovskii and A. S. Ukolov. 19(10), 1303–7 (Apr. 1975); CPM-7506X0237

Ul'yanov, K. N.—Axially symmetric neutralized electron beam —G. N. Vyalov, V. N. Evteev, Yu. M. Zolotaikin, and K. N. Ul'yanov. 19(11), 1414–7 (May 1975); CPM-7506X1168

Urman, Yu. M.—Ponderomotive forces on a rotating conducting sphere in a time-varying inhomogeneous magnetic field —R. V. Lin'kov and Yu. M. Urman. 19(11), 1393–8 (May 1975); CPM-7506X1147

Ushatkin, E. F.—Dispersion of the dielectric constant of crystalline KH_2PO_4 near the "soft" mode frequency —V. V. Meriakri, Yu. M. Poplavko, and E. F. Ushatkin. 19(5), 703–4 (Nov. 1974); CPM-7501X0497

Ushkov, V. L.—Titanium-pump system for hydrogen —K. G. Mirzoev, V. G. Rogozinskii, and V. L. Ushkov. 19(3), 432–3 (Sep. 1974); CPM-7412X1118

Usov, Yu. P.—Reflection of a high-current relativistic electron beam from a conducting surface —A. N. Didenko, A. I. Ryabchikov, V. A. Tuzov, and Yu. P. Usov. 19(12), 1625–6 (Jun. 1975); CPM-7508X0499

Ustinov, Yu. K.—Titanium adsorption on tungsten —Yu. K. Ustinov and S. V. Fedichev. 19(8), 1118–9 (Feb. 1975); CPM-7504X1542

Ustyugov, V. I.—Unidirectional cw oscillation in a solid state ring laser with a return mirror —A. A. Mak, V. I. Ustyugov, V. A. Fromzel', and M. M. Khaleev. 19(4), 552–3 (Oct. 1974); CPM-7412X0336

V

Vagner, I. V.—Cell for forming electron beams of arbitrary shape in a high-voltage gaseous discharge —I. V. Vagner, É. I. Bolgov, V. F. Grakun, V. L. Gokhfel'd, and V. A. Kudlai. 19(8), 1042–5 (Feb. 1975); CPM-7504X1466

Vagner, S. D.—Electron energy distribution in a high-freqeuncy discharge in an axial magnetic field —S. D. Vagner, V. A. Virolainen, Yu. M. Kagan, and T. A. Kalmykova. 19(2), 290–1 (Aug. 1974); CPM-7408X1554

—High-frequency discharge in a mercury—helium mixture —S. D. Vagner, Yu. M. Kagan, A. I. Konstantinov, and I. S. Niskonen. 19 (7), 898–900 (Jan. 1975); CPM-7503X0786

Vainer, B. V.—Ionization oscillations in a plasma in the presence of ionizing radiation —B. V. Vainer. 19(1), 119–20 (Jul. 1974); CPM-7407X1631

Vakhrushin, Yu. P.—Estimate of the angular divergence in intense electron beams —V. S. Kuznetsov, Yu. P. Vakhrushin, O. L. Komarov, and R. P. Fidel'skaya. 19(7), 868–70 (Jan. 1975); CPM-7503X0756

Vasil'ev, N. M.—Neutral particles from the interaction of laser radiation with a solid target —Yu. A. Bykovskii, N. M. Vasil'ev, I. D. Laptev, and V. N. Nevolin. 19(12), 1635 (Jun. 1975); CPM-7508X0509

Vasil'eva, I. A.—Electron energy distribution in helium, nitrogen, and their mixtures —K. D. Asvadurov, I. A. Vasil'eva, and V. M. Torchinskii. 19(3), 354–7 (Sep. 1974); CPM-7412X1040

Vasserman, S. B.—Resistance and inductance of a gas arc —S. I. Barannik, S. B. Vasserman, and A. N. Lukin. 19(11), 1449–53 (May 1975); CPM-7506X1203

Vaulin, L. N.—Proton extraction from the 70-GeV accelerator for the Ludmila liquid-hydrogen chamber (extraction system S) —A. A. Aseev, A. I. Drozhdin, B. A. Zelenov, É. A. Merker, L. L. Moizhes, K. P. Myznikov, A. A. Roshchin, V. M. Tatarenko, M. A. Kholodenko, A. D. Artemov, L. N. Vaulin, V. I. Gordin, I. I. Kovalevskii, V. N. Rozhkov, M. M. Suvorov, A. S. Sudarushkin, and V. I. Chuiko. 19(1), 70–6 (Jul. 1974); CPM-7407X1582

Veisig, G. S.—Two-section solenoid with internal "equally-loaded" section; power as a function of the length of the internal section — G. S. Veisig, A. P. Doroshenko, and P. P. Rybin. 19(3), 416–8 (Sep. 1974); CPM-7412X1102

Vigasin, A. A.—Nonlinear spherical aberrations and thermoelastic stresses in thermal self-focusing —A. A. Vigasin, Yu. A. Gorokhov, A. P. Sukhorukov, and A. M. Khachatryan. 19(5), 673–5 (Nov. 1974); CPM-7501X0467

Vigdorchik, I. M.—Peak current in a cold-cathode magnetron —I. M. Vigdorchik and V. P. Timofeev. 19(1), 142–3 (Jul. 1974); CPM-7407X1654

Vikulov, V. F.—Multiple-section linear electron accelerator with synchronized oscillators —V. F. Vikulov, V. A. Volodin, and O. S. Milovanov. 19(7), 930–1 (Jan. 1975); CPM-7503X0818

Vil'dzhyunas, M. I.—Generation of drift waves by an rf field near the lower hybrid frequency —Yu. F. Baranov, D. G. Bulyginskii, M. I. Vil'dzhyunas, B. V. Galaktionov, and N. V. Shustova. 19(6), 732–5 (Dec. 1974); CPM-7501X0732

Vinogradov, S. S.—Shielding properties of superconducting shields — S. I. Bondarenko, S. S. Vinogradov, G. A. Gogadze, S. S. Perepelkin, and V. I. Sheremet. 19(6), 824–8 (Dec. 1974); CPM-7501X0824

Vinogradov, V. F.—Composition of adsorbing and desorbing fluxes — Yu. A. Gel'man, V. I. Mikhailov, V. F. Vinogradov, and Yu. N. Lyubitov. 19(10), 1355–8 (Apr. 1975); CPM-7506X0289

Vinogradov, V. P.—Plasma density in a magnetoplasma compressor —A. K. Vinogradova, V. P. Vinogradov, A. I. Morozov, and A. A. Sergeev. 19(3), 421–3 (Sep. 1974); CPM-7412X1107

Vinogradova, A. K.—Plasma density in a magnetoplasma compressor —A. K. Vinogradova, V. P. Vinogradov, A. I. Morozov, and A. A. Sergeev. 19(3), 421–3 (Sep. 1974); CPM-7412X1107

Vinogradova, E. B.—Dependence of the basic parameters of $Al_xGa_{1-x}As$—GaAs solar converters on temperature and optical intensity —E. B. Vinogradova, M. B. Kagan, N. S. Koroleva, T. L. Lyubashevskaya, and T. A. Nuller. 19(10), 1378–81 (Apr. 1975); CPM-7506X0312

Virko, V. F.—Plasma synthesis by injection of an electron beam through an ion source —V. F. Virko, M. D. Gabovich, G. S. Kirichenko, and O. K. Nazarenko. 19(11), 1418–20 (May 1975); CPM-7506X1172

Virolainen, V. A.—Electron energy distribution in a high-freqeuncy discharge in an axial magnetic field —S. D. Vagner, V. A. Virolainen, Yu. M. Kagan, and T. A. Kalmykova. 19(2), 290–1 (Aug. 1974); CPM-7408X1554

Vitrishchak, I. B.—Polarization of a cavity with a thermally deformed active element —I. B. Vitrishchak, L. N. Soms, and A. A. Tarasov. 19(5), 664–8 (Nov. 1974); CPM-7501X0458

Vlasov, V. V.—Plasma decay instability in crossed fields —V. I. Farenik, V. V. Vlasov, A. M. Rozhkov, and A. A. Kozharin. 19(8), 1116–7 (Feb. 1975); CPM-7504X1540

—Ion energy spectra and collective effects in a Penning ion source — V. I. Farenik, V. V. Vlasov, A. M. Rozhkov, and A. A. Kozharin. 19(9), 1258–9 (Mar. 1975); CPM-7505X0680

Voitsenya, V. S.—Electron temperature in a high-frequency helium discharge —V. S. Voitsenya, A. Yu. Voloshko, V. G. Konovalov, and S. I. Solodovchenko. 19(7), 909–10 (Jan. 1975); CPM-7503X0797

Volkov, A. A.—Temperature dependence of the dielectric permittivity of single-crystal TiO_2 in the submillimeter range —A. A. Volkov, N. A. Irisova, and G. V. Kozlov. 19(4), 567–8 (Oct. 1974); CPM-7412X0351

Volkov, M. P.—Effects of cleaning on adsorption by germanium single crystals —Yu. I. Belyakov, M. P. Volkov, and T. N. Kompaniets. 19(6), 815–6 (Dec. 1974); CPM-7501X0815

Volkov, N. V.—Effect of selenium and sulfur on the work function of tungsten —N. V. Volkov, Yu. K. Gus'kov, Z. N. Kononova, and Yu. I. Kostikov. 19(1), 144–5 (Jul. 1974); CPM-7407X1656

—Steady-state operation of a surface-ionization thermionic converter —N. V. Volkov, Yu. K. Gus'kov, Yu. I. Kostikov, and V. P. Pashchenko. 19(8), 1129–30 (Feb. 1975); CPM-7504X1553

Volkov, Ya. F.—Magnetic field in a θ pinch with an axial conductor —Ya. F. Volkov, V. G. Dyatlov, and N. I. Mitina. 19(3), 323–5 (Sep. 1974); CPM-7412X1009

—Optical investigation of a turbulent plasma —Ya. F. Volkov, V. G. Dyatlov, and N. I. Mitina. 19(7), 905–8 (Jan. 1975); CPM-7503X0793

Volobuev, P. V.—Diffusion and solubility of helium in potassium chloride —A. Ya. Kupryazhkin, P. V. Volobuev, and P. E. Suetin. 19(8), 1105–7 (Feb. 1975); CPM-7504X1529

Volodin, V. A.—Multiple-section linear electron accelerator with synchronized oscillators —V. F. Vikulov, V. A. Volodin, and O. S. Milovanov. 19(7), 930–1 (Jan. 1975); CPM-7503X0818

Voloshko, A. Yu.—Electron temperature in a high-frequency helium discharge —V. S. Voitsenya, A. Yu. Voloshko, V. G. Konovalov, and S. I. Solodovchenko. 19(7), 909–10 (Jan. 1975); CPM-7503X0797

Volosov, V. I.—Mechanism for plasma loss from a magnetic trap — V. I. Volosov. 19(11), 1408–11 (May 1975); CPM-7506X1162

Vorob'eva, N. A.—Effect of cathode emission on the threshold for striations —N. A. Vorob'eva, Yu. M. Kagan, V. M. Milenin, and A. Kh. Muradov. 19(1), 117–8 (Jul. 1974); CPM-7407X1629

Vorogushin, M. F.—Resonator with azimuthally varying end plates —M. F. Vorogushin and V. I. Petrunin. 19(6), 767–9 (Dec. 1974); CPM-7501X0767

—Azimuthal and vertical motion in an accelerator with azimuthally varying electric field —M. F. Vorogushin and V. I. Petrunin. 19(6), 770–2 (Dec. 1974); CPM-7501X0770

—Phase motion of particles in an accelerator with an azimuthally varying electric field —M. F. Vorogushin and V. I. Petrunin. 19(7), 926–9 (Jan. 1975); CPM-7503X0814

Voronin, V. S.—Magnetic-field transport of a high-current electron beam —A. V. Agafonov, V. S. Voronin, A. N. Lebedev, and K. N. Pazin. 19(9), 1188–92 (Mar. 1975); CPM-7505X0610

Voronkov, R. M.—Low-voltage gun with a resonator for formation of electron bunches in a linear accelerator —V. A. Boiko, R. M. Voronkov, and V. A. Danilichev. 19(4), 569–71 (Oct. 1974); CPM-7412X0353

Vovk, O. M.—Analysis of magnetic deflection systems —O. M. Vovk and O. Ya. Popov. 19(11), 1504 (May 1975); CPM-7506X1258

Vul'gal'ter, G. A.—Magnetoacoustic transducer based on the domain structure of a ferromagnetic material —G. L. Gurevich and G. A. Vul'gal'ter. 19(1), 154–5 (Jul. 1974); CPM-7407X1666

Vyalov, G. N.—Multiple scattering of a focused beam of monoenergetic electrons —G. N. Vyalov. 19(9), 1216–8 (Mar. 1975); CPM-7505X0638

—Axially symmetric neutralized electron beam —G. N. Vyalov, V. N. Evteev, Yu. M. Zolotaikin, and K. N. Ul'yanov. 19(11), 1414–7 (May 1975); CPM-7506X1168

Y

Yakovkin, I. B.—Optical methods for studying amplification of elastic surface waves in a stratified system —I. B. Yakovkin, V. V. Petrov, and S. V. Bogdanov. 19(9), 1242–5 (Mar. 1975); CPM-7505X0664

Yakovleva, M. N.—Electromagnetic fields outside a synthesized plasma jet —E. V. Bogdanov, G. M. Mantrova, and M. N. Yakovleva. 19(7), 919–21 (Jan. 1975); CPM-7503X0807

Yakushev, E. M.—A transaxial lens —V. M. Kel'man, L. M. Nazarenko, and E. M. Yakushev. 19(4), 523–5 (Oct. 1974); CPM-7412X0307

—Theory of the cathode lens. III. Derivation of equations for composite cathode lenses —V. M. Kel'man, A. A. Sapargaliev, and E. M. Yakushev. 19(5), 592–6 (Nov. 1974); CPM-7501X0386

—Theory of the cathode lens. IV. Aberrations of composite cathode lens —V. M. Kel'man, A. A. Sapargaliev, and E. M. Yakushev. 19(5), 597–9 (Nov. 1974); CPM-7501X0391

Yalamov, Yu. I.—Thermophoresis and diffusophoresis of small, volatile aerosol particles —Yu. I. Yalamov and E. R. Shchukin. 19(2), 278–9 (Aug. 1974); CPM-7408X1542

—Motion of stable aerosol particles —O. A. Barsegyan and Yu. I. Yalamov. 19(11), 1486–7 (May 1975); CPM-7506X1240

Yalovets, A. P.—Ionization of a gas-discharge gap by fast electrons —O. B. Evdokimov and A. P. Yalovets. 19(1), 138–9 (Jul. 1974); CPM-7407X1650

Yampol'skii, P. A.—Nonradiative electron transitions and thermal effects in laser-irradiated transparent dielectrics —B. I. Makshantsev, A. A. Kovalev, R. K. Leonov, and P. A. Yampol'skii. 19(1), 98–102 (Jul. 1974); CPM-7407X1610

Yankauskas, Z. K.—Skin effect in a constant magnetic field —Z. K. Yankauskas, V. I. Chesonis, and V. G. Skripnik. 19(9), 1251–2 (Mar. 1975); CPM-7505X0673

Yankelevich, Yu. B.—Thermal conditions for a sandwich cold cathode —F. M. Benson, P. E. Troyan, and Yu. B. Yankelevich. 19(7), 946–7 (Jan. 1975); CPM-7503X0834

Yanshin, É. V.—Investigating prebreakdown fields in water by means of the Kerr effect —I. T. Ovchinnikov, K. V. Yanshin, and É. V. Yanshin. 19(2), 294–5 (Aug. 1974); CPM-7408X1558

Yanshin, K. V.—Investigating prebreakdown fields in water by means of the Kerr effect —I. T. Ovchinnikov, K. V. Yanshin, and É. V. Yanshin. 19(2), 294–5 (Aug. 1974); CPM-7408X1558

Yavor, I. P.—Interferometer measurement of the neutral cesium distribution in a short low-voltage arc —Yu. L. Serov and I. P. Yavor. 19(6), 751–4 (Dec. 1974); CPM-7501X0751

—Atomic density in the low-voltage arc in a cesium diode —F. G. Baksht, A. A. Kostin, Yu. L. Serov, and I. P. Yavor. 19(11), 1424–5 (May 1975); CPM-7506X1178

Yuferov, V. B.—Spatial characteristics and loss of plasma produced by an electron beam in a magnetic trap —M. Yu. Bredikhin, A. I. Maslov, A. I. Skibenko, E. I. Skibenko, I. P. Fomin, and V. B. Yuferov. 19(1), 49–52 (Jul. 1974); CPM-7407X1561

Yurchenko, V. I.—Computer calculation of quasistationary pulsed magnetic fields —V. I. Yurchenko. 19(8), 1025–30 (Feb. 1975); CPM-7504X1449

—Flux loss in the production of ultrastrong fields by rapid compression of conducting shells —V. I. Yurchenko. 19(8), 1031–3 (Feb. 1975); CPM-7504X1455

—Equations and boundary conditions for a three-dimensional quasistationary field —V. I. Yurchenko. 19(8), 1126–8 (Feb. 1975); CPM-7504X1550

Yurevichyus, Sh. V.—Optical simulation of a radiator aperture with arbitrary amplitude–phase distribution —M. M. Butusov and Sh. V. Yurevichyus. 19(6), 833–4 (Dec. 1974); CPM-7501X0833

Yushmanov, E. E.—Measurement of plasma ion temperature by a thin probe with $T_i \gtrsim T_e$ —B. I. Kanaev and E. E. Yushmanov. 19(4), 554–5 (Oct. 1974); CPM-7412X0338

—Measurement of plasma electron temperature with a sinusoidal probe potential —B. I. Kanaev, V. V. Piterskii, and E. E. Yushmanov. 19(11), 1421–3 (May 1975); CPM-7506X1175

Z

Zagorskii, P. V.—Lagrange problem in magnetohydrodynamics —P. V. Zagorskii and Yu. P. Lun'kin. 19(8), 1009–11 (Feb. 1975); CPM-7504X1433

Zaitsev, V. K.—Laser compensation for thermal distortion in optical pumping —V. K. Zaitsev, V. A. Il'inskii, A. M. Marugin, and V. M. Ovchinnikov. 19(11), 1480–1 (May 1975); CPM-7506X1234

Zaitsev, V. V.—Electron energy distribution and electrical characteristics of the positive column in H_2 and H_2+Cl_2 —V. V. Zaitsev, A. I. Maksimov, and V. I. Svettsov. 19(1), 57–9 (Jul. 1974); CPM-7407X1569

Zakatov, L. P.—Scattering of an electron beam in a straight *dc* turbulent plasma —Yu. P. Golovanov, L. P. Zakatov, A. S. Kingsep, and A. G. Plakhov. 19(8), 1046–9 (Feb. 1975); CPM-7504X1470

Zakharenko, Yu. G.—Mode coupling in a double-anode discharge —Yu. G. Zakharenko and V. E. Privalov. 19(7), 980–2 (Jan. 1975); CPM-7503X0868

This index is based on the 1975 *Physics and Astronomy Classification Scheme* developed by AIP. It is not a translation. It was produced by computer-aided photocomposition directly from the magnetic tapes of the AIP's Current Physics Information System. Suggestions for improvements as well as other comments are welcome and should be addressed to the Editor.

This index includes microfilm reel and frame numbers for the convenience of those wishing to find articles in *Current Physics Microform* (CPM), the monthly microfilm edition of the complete set of journals of the American Institute of Physics. These numbers are given in the form **CPM-7201A0321**, where 72 refers to the year, 01 denotes the month (January in this example), A the cartridge, and 0321 the frame.

Focusing of an astigmatic beam by a doublet and a symmetric triplet of quadrupole lenses

V. I. Chetvertkov
D. V. Efremov NIIEFA, Leningrad

(Submitted April 6, 1973)
Zh. Tekh. Fiz., 44, 3-5 (January 1974)

Using a matrix method analytic expressions are obtained in the semithin-lens approximation for the optical parameters and gradients necessary to focus astigmatic beams for given lens geometries and object and image positions.

The solution of the inverse problem of particle optics – finding the magnitudes of the focusing fields and the optical parameters of the lenses for given beam requirements and configurations and known geometry – can facilitate the synthesis of optical systems.

We consider the solution of this problem for a doublet and a symmetric triplet for astigmatic beams with a small space charge as the matching of objects and images. We use the semithin approximation for quadrupole lenses.[1,2] The solution of this problem is known only for a doublet.[3] Figure 1 shows particle trajectories in perpendicular planes in a symmetric triplet. Trajectories in a doublet are constructed in similar fashion. Letters with subscripts and superscripts are used in Fig. 1 and in the test. Subscripts 1 and 2 refer to the corresponding gradient and superscripts denote the number of primes. Equivalent thin lenses with optical strengths g_m^n pass through the centers of the poles with the effective length L_m; d is the distance between centers of neighboring poles; a^n is the distance from the object to the entrance and b^n from the image to the exit. Without loss of generality Fig. 1 is drawn for $b'' < 0$, a^n, $b' > 0$.

We use a matrix method to describe the optics. The relation between a^n and b^n is given by[1]

$$b^n(A_{21}^n a^n + A_{22}^n) + (A_{11}^n a^n + A_{12}^n) = 0. \tag{1}$$

$$A^n = \begin{pmatrix} A_{11}^n & A_{12}^n \\ A_{21}^n & A_{22}^n \end{pmatrix}$$

is the transfer matrix between entrance and exit.

We introduce the notation

$$x_m^n = g_m^n d,\ A_m^n = \begin{pmatrix} 1 & 0 \\ -\frac{1}{d} x_m^n & 1 \end{pmatrix},\ A_d = \begin{pmatrix} 1 & d \\ 0 & 1 \end{pmatrix}.$$

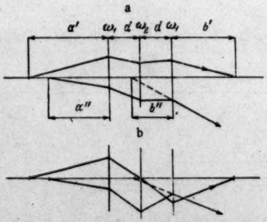

Fig. 1. Trajectories in a symmetrical triplet. $a' = 1$, $a'' = 0.75$, $b' = 0.784$, $b'' = -0.507$, $d = 0.4$, $L_1 = 0.2$, $L_2 = 0.4$ (dimensions in meters). a) Weak solution ($y_1 = 0.366$, $y_2 = 0.619$, $\omega_1 = 0.625$, $\omega_2 = 0.835$); b) strong solution ($y_1 = 0.730$, $y_2 = 1.245$, $\omega_1 = 0.919$, $\omega_2 = 1.294$).

In the semithin approximation

$$x_m^n = \begin{cases} \frac{d}{L_m}\omega_m \sin\omega_m & \text{for}\quad n = m, \\ -\frac{x_m^m}{1-\delta_m x_m^m} & \text{for}\quad n \neq m, \end{cases} \tag{2}$$

where $\delta_m = L_m/3d$.

We find the matrices for a doublet

$$A^n = A_2^n A_d A_1^n = \begin{pmatrix} (1 - x_1^n) & d \\ -\frac{1}{d}[(1 - x_1^n)x_2^n + x_1^n]; & (1 - x_2^n) \end{pmatrix} \tag{3}$$

and a symmetric triplet

$$A^n = A_1^n A_d A_2^n A_d A_1^n$$

$$= \begin{pmatrix} [(1 - x_1^n)(1 - x_2^n) - x_1^n]; & d(2 - x_2^n) \\ -\frac{1}{d}(1 - x_1^n)[(1 - x_1^n)x_2^n + 2x_1^n]; & A_{11}^n \end{pmatrix}. \tag{4}$$

Clearly $|A^n| = 1$. Using (1), (2), (3), or (4) for two values of n we obtain two equations for x_1' and x_2''. These equations can be written in compact form:

$$\sum_{p=0}^{N} h_{s,p} \cdot (x_1')^{N-p} = 0, \tag{5}$$

$$x_2'' = \frac{\sum\limits_{p=0}^{\frac{N}{2}} h_{q,p}(x_1')^{\frac{N}{2}-p}}{\sum\limits_{p=0}^{\frac{N}{2}} h_{q+1,p}(x_1')^{\frac{N}{2}-p}}, \tag{6}$$

where

$$h_{s,p} = \sum_{\nu=\nu_1}^{\nu_2} \sum_{\mu=1}^{2} (-1)^{\mu} h_{\mu,p-\nu} h_{s-\mu,\nu}.$$

$\nu_1 = p - \nu_2$, $\nu_2 = p$ for $p \leq 1$, $\nu_2 = (N/2)$ for $p > 1$.

For a doublet $N = 2$, $h_{10} = \beta'$, $h_{11} = -(\eta' - 1)$, $h_{20} = -(1 - \delta_2 h_{10})$, $h_{21} = (\alpha' + \delta_2 h_{11})$, $h_{30} = (\beta'' - \delta_1 h_{31})$, $h_{31} = (\eta'' - 1)$, $h_{40} = (1 - \delta_1 h_{41})$, $h_{41} = \alpha''$; for a symmetric triplet $N = 4$, $h_{10} = -2$, $h_{11} = 2(\theta' - 1)$, $h_{12} = -(2\eta' - \theta')$, $h_{20} = (1 - 2\delta_2)$, $h_{21} = -(\theta' - \delta_2 h_{11})$, $h_{22} = (\eta' + \delta_2 h_{12})$, $h_{30} = 2 - \delta_1[2(\theta'' - 1) - \delta_1 h_{32}]$, $h_{31} = 2[(\theta'' - 1) - \delta_1 h_{32}]$, $h_{32} = (2\eta'' - \theta'')$, $h_{40} = 1 - \delta_1(\theta'' - \delta_1\eta'')$, $h_{41} = (\theta'' - 2\delta_1\eta'')$, $h_{42} = \eta''$, where

$$\alpha^n = \left(1 + \frac{d}{a^n}\right),\ \beta^n = \left(1 + \frac{d}{b^n}\right),\ \eta^n = \alpha^n\beta^n,\ \theta^n = (\alpha^n + \beta^n).$$

Equation (5) is solved analytically. The value of x_2''

is found by substituting x_1' into (6). It is possible to take $q = 1$ or 3. From its meaning $x_m^m > 0$, and therefore of all possible solutions of (5) and (6) we retain only those which give positive pairs x_1' and x_2''. The solutions corresponding to maximum x_m^m are called "strong".[2] Using the values found for x_1' and x_2'' we compute x_1'' and x_2' and then g_m^n. Using x_m^n we determine the matrix A^n from (3) or (4). The optical parameters of the lenses are found. To calculate the gradients we must determine ω_m. We use (2) for $n = m$ in the form

$$y_m = \omega_m \sin \omega_m, \quad y_m = \frac{L_m}{d} x_m^m. \tag{7}$$

Making a Taylor's expansion of the function ω_m defined implicitly by (7), limiting ourselves to a few terms, and simplifying the coefficients we obtain

$$\omega_m \approx \sqrt{y_m}\left\{1 + \frac{y_m}{12}\left[1 + \frac{y_m}{4}\sum_{l=0}^{2}\left(\frac{y_m}{3}\right)^l\right]\right\}. \tag{8}$$

The relative error in computing ω_m from (8) is

$$\frac{\Delta\omega_m}{\omega_m} < 2 \cdot 10^{-4}\,(5 \cdot 10^{-3}) \text{ for } y_m < 0.85\,(1.25).$$

The values found for ω_m can be improved by Newton's method

$$\omega_m^{i+1} = \omega_m^i + \frac{y_m - \omega_m^i \sin \omega_m^i}{\sin \omega_m^i + \omega_m^i \cos \omega_m^i},$$

where i is the number of the approximation.

We determine the gradients from the known values of ω_m. For example, for magnetic lenses[3]

$$G_m = \left(\frac{\omega_m}{L_m}\right)^2 (BR),$$

where G_m is the gradient in T/m, BR is the magnetic rigidity of the particles in Tm, and L_m is in m.

A numerical example for a symmetric triplet is shown in Fig. 1. The relations obtained offer an effective method of calculating the focusing of astigmatic beams in ray optics and give a first approximation to envelope optics.

Round metal-optical waveguide filled with a two-layer dielectric

V. A. Pruzhanovskii

(Submitted July 24, 1972; resubmitted February 14, 1973)
Zh. Tekh. Fiz., 44, 6-15 (January 1974)

The theoretical section of this paper deals with the application of the characteristic equation for a three-layer coaxial structure to a round metal-optical waveguide filled with a two-layer dielectric, and also to an open two-layer dielectric waveguide with finite sheath thickness. An approximate solution based on the use of an asymptotic expansion of Bessel functions is obtained. Results of a numerical calculation are given. The second part of the article is devoted to an experimental investigation of this waveguide. Both single-mode and multimode designs, obtained by chemical silvering of a two-layer glass fiber, are considered. A procedure is described for measuring the fiber parameters and a method is given for silvering. Measurement results are cited and show that when the sheath is thick the silvering of the outer surface of the fiber decreases the attenuation of the waves propagating in the core. At the same time, silvering a fiber with a thin sheath increases this attenuation. Certain waveguide properties observed in the present study are discussed and practical applications of such a waveguide are discussed.

INTRODUCTION

Earlier articles[1,2] have dealt with coaxial and circular metal-optical waveguides. The present paper is devoted to a round waveguide filled with a two-layer dielectric in which the refractive index of the outer layer is somewhat lower than that of the inner one.

The use of a metallic shield to decrease the losses in a two-layer planar dielectric light pipe is discussed in ref. 3. Round metallic waveguides filled with a two-layer dielectric are investigated at microwave frequencies in refs. 4-7. The metal is regarded as a medium of infinite conductivity, and the problem is solved with zero boundary conditions. This method cannot be used at optical frequencies, where the metal must be regarded as a dielectric with a complex permittivity $\overset{*}{\varepsilon} = \varepsilon - i(4\pi\sigma/\omega)$ and it is necessary to solve the characteristic equation for a three-layer structure.

Such an equation has been solved in refs. 8 and 9. The method used in the first of these references, however, is not suitable for the determination of the damping introduced by the outer absorbing coating. The successive-approximation method developed in the second references calls for the use of a computer.

In contrast, the purpose of the theoretical part of the present paper is to obtain equations for the damping in an open and metallized two-layer fiber in explicit form.

The experimental section is devoted to the influence of metallization on the damping of the light flux and on its polarization in a two-layer glass fiber. There seem to be no other papers published on this question.

THEORY

Characteristic equation. The waveguide construction is shown in Fig. 1. It consists of a dielectric core I of radius ρ and refractive index n_1, of a dielectric sheath II with outer radius R and refractive index n_2 ($n_2 < n_1$), and of an outer metallic cover III. The outside radius of this cover should be regarded as infinite in view of the small skin depth in the metal. For the sake of comparison, we consider later the case in which medium III is free space or air.

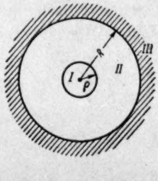

Fig. 1. Construction of the waveguide.

We turn to the previously derived[2] characteristic equation (1) for a three-layer coaxial waveguide (changing the index numbers of the media, in accord with Fig. 1). Of the solutions of this equation we are interested primarily in those corresponding to waves propagating in the core and attenuating in the sheath. Such solutions correspond to values of χ_2 lying near the imaginary axis in the complex plane, and to values χ_1 located near the real axis.

If the sheath is thick enough, $|\chi_2|R \gg 1$ so that we can apply the asymptotic Hankel expansion[10] to the functions $J_n(\chi_2R)$ and $N_n(\chi_2R)$. Substituting it in the indicated equation and neglecting terms of higher order than $\exp[-2|\chi_2|R]$, we represent this equation in the form

$$\left[\frac{J_n'(\chi_1\rho)}{J_n(\chi_1\rho)}\right]^2\frac{\varepsilon_1\mu_1\chi_2^2}{\varepsilon_2\mu_2\chi_1^2}-\frac{J_n'(\chi_1\rho)}{J_n(\chi_1\rho)}\frac{H_n^{(1)\prime}(\chi_2\rho)}{H_n^{(1)}(\chi_2\rho)}\frac{\chi_2}{\chi_1}\left(\frac{\varepsilon_1}{\varepsilon_2}+\frac{\mu_1}{\mu_2}\right)+\left[\frac{H_n^{(1)\prime}(\chi_2\rho)}{H_n^{(1)}(\chi_2\rho)}\right]^2$$
$$-\frac{\Gamma^2k_0^2n^2}{\chi_1^4\chi_2^2\rho^2}\left(1-\frac{\varepsilon_1\mu_1}{\varepsilon_2\mu_2}\right)^2+(-1)^n\frac{i8e^{i2\chi_2R}}{\pi\chi_2\rho qS_n^2(i2\chi_2R)\,[H_n^{(1)}(\chi_2\rho)]^2}$$
$$\times\left\{-\frac{J_n'(\chi_1\rho)}{J_n(\chi_1\rho)}\left(\gamma_*+\frac{i\alpha_*\psi}{2}\right)-\frac{\xi\pi^2\chi_2^2\rho R}{4}+\frac{H_n^{(1)\prime}(\chi_2\rho)}{H_n^{(1)}(\chi_2\rho)}(i\psi+\beta)\right\}=0, \quad (1)$$

where $S_n(z) = 1 + (4n^2-1)/4iz + \ldots$ is the series in the Hankel expansion,[10]

$$\alpha_*=\frac{\chi_2}{\chi_1}\left(\frac{\varepsilon_1}{\varepsilon_2}+\frac{\mu_1}{\mu_2}\right),\quad \gamma_*=\frac{H_n^{(1)\prime}(\chi_3R)}{H_n^{(1)}(\chi_3R)}\frac{\chi_2^2}{\chi_1\chi_3}\left(\frac{\varepsilon_1\varepsilon_3}{\varepsilon_2^2}+\frac{\mu_1\mu_3}{\mu_2^2}\right),$$
$$u\approx -i/2\chi_2R,\quad q=1+\zeta-i\beta+u(2-i\beta+u),$$
$$\psi=2(1+u)-qS_n(i2\chi_2R)\,S_n(-i2\chi_2R),$$

and the remaining notation is the same as in ref. 2.

The last term of this equation is small, since it contains the factor $\exp(-2|\chi_2|R)$. The remaining four terms coincide with the characteristic equation for a two-layer dielectric waveguide.[11] It is noteworthy that both the radius R and the parameters of the medium III enter only in the last term. The small value of this term corresponds to a small perturbation introduced by medium III into the structure of the waves propagating in dielectrics I and II.

Approximation solution. The characteristic equation (1) has complex coefficients with small imaginary parts. Its roots should therefore lie near the real roots of the real part of this equation. Since the latter, owing to the insignificance of the fifth term, coincide with the characteristic equation for a two-layer dielectric waveguide, we can use the approximate solution methods developed for the latter[12,13] and determine the real part of the root Re χ_1.

For example, for an He_{11} wave, we can use the approximation[13]

$$\operatorname{Re}\chi_1 \approx \frac{3\pi(1+\sqrt{2})\sqrt{\varepsilon_1-\varepsilon_2}}{\lambda\left\{1+\left[4+\left(\frac{2\pi\rho}{\lambda}\right)^4(\varepsilon_1-\varepsilon_2)^2\right]^{1/4}\right\}}. \tag{2}$$

For $J_n'(\chi_1\rho)/J_n(\chi_1\rho)$ and $H_n^{(1)'}(\chi_2\rho)/H_n^{(1)}(\chi_2\rho)$ we use an asymptotic expansion analogous to Eq. (16) of ref. 2 (the arguments of these functions for the practically realizable constructions of two-layer glass fibers[14] never drop below 0.9):

$$\frac{J_n'(z_1)}{J_n(z_1)} \approx f(y_{nm}-|z_1|), \tag{3}$$

$$\frac{H_n^{(1)'}(z_2)}{H_n^{(1)}(z_2)} \approx i\left(1+\frac{ig}{2z_2}\right). \tag{4}$$

Here, y_{nm} is the m-th zero of the derivative $J_n'(z)$, in the vicinity of which there are located the roots of (1) corresponding to the modes HE_{nm} and EH_{nm} (or H_{0m} and E_{0m} if n = 0), f and g are correction coefficients determined for $z_{10} = \operatorname{Re}(\chi_1)\rho$ and $z_{20} = i|\chi_{20}|\rho = (i\rho)[|k_1|^2 - |k_2|^2 - (\operatorname{Re}\chi_1)^2]^{1/2}$ by substituting the coresponding numerical values of the functions in (3) and (4).

We write the roots of Eq. (1) in the form $\chi_1 = |\chi_1|e^{i\varphi_1}$ and $\chi_2 = i|\chi_2|e^{i\varphi_2}$. If medium III is a metal, then we can write $\chi_1 \approx |\chi_1|$, $\chi_2 \approx i|\chi_2|$, $\dot{\varepsilon}_1 \approx \varepsilon_1$, $\dot{\varepsilon}_2 \approx \varepsilon_2$, and $\alpha_* \approx i|\alpha_*|$, since φ_1, φ_2, Δ_1, and Δ_2 are much smaller than the arguments of the complex quantities β, γ_*, and ζ. If the medium III is a dielectric (say, air), we can neglect this term completely.

Separating the imaginary part of Eq. (1) and solving it, we find

$$\varphi_1 = \frac{\Sigma + \operatorname{Im}\Omega}{\Delta}, \tag{5}$$

where we use the notation

$$\sum = \frac{f^2\varkappa^2\nu(2\tau-\Delta)}{\theta^2} + f\varkappa\left(|\alpha_*|\tau - \frac{\varepsilon_1\nu\Delta}{\varepsilon_2|\theta|}\right) + \frac{g\tau\nu}{|\chi_2|\rho} + \frac{\Gamma^2|k_2|^2n^2(1-\upsilon)^2}{|\chi_2|^2\rho^2|\chi_1|^4}\left(\frac{\upsilon\Delta}{1-\upsilon} + \frac{2\tau\theta^2}{1-\theta^2}\right), \tag{6}$$

$$\Delta = 2f^2\varkappa^2\upsilon\left(\frac{y_{nm}}{\varkappa\theta^2} - 1\right) + f|\alpha_*|(\nu y_{nm} - \varkappa\theta^2) - \frac{g\nu\theta^2}{|\chi_2|\rho} + \frac{2\Gamma^2|k_2|^2n^2(2+\theta^2)(1-\upsilon)^2}{|\chi_1|^4|\chi_2|^2\rho^2}, \tag{7}$$

$$\Omega = \frac{i2\pi e^{i2\chi_2R}}{\chi_2\rho q[S_n(i2\chi_2R)]^2[K_n(-i\chi_2\rho)]^2} \times\left\{\frac{J_n'(\chi_1\rho)}{J_n(\chi_1\rho)}\left(\gamma_* + \frac{i\alpha_*\psi}{2}\right) + \frac{\xi\pi^2\chi_2^2\rho R}{4} - \frac{H_n^{(1)'}(\chi_2\rho)}{H_n^{(1)}(\chi_2\rho)}(i\psi+\beta)\right\}. \tag{8}$$

$K_n(-i\chi_2\rho)$ is the MacDonald function, and

$$\varkappa = y_{nm} - |\chi_1|\rho,\ \Delta = \operatorname{tg}\Delta_1 - \operatorname{tg}\Delta_2,$$

$$\dot{\varepsilon}_1 = \varepsilon_1(1 - i\operatorname{tg}\Delta_1),\ \dot{\varepsilon}_2 = \varepsilon_2(1 - i\operatorname{tg}\Delta_2),$$

$$\theta = i\left|\frac{\chi_1}{\chi_2}\right|,\ \nu = 1 + (g/2|\chi_2|\rho),\ \upsilon = \varepsilon_1\mu_1/\varepsilon_2\mu_2.$$

The first term in this expression characterizes the damping of the light flux in the core material, the second introduces a correction for the field distribution and for the differences between the losses in the core and in the sheath. Both terms taken together determine the damping in a dielectric waveguide in the two-layer approximation, i.e., at R = ∞.

Substituting (5) in the equation $\Gamma = (k_1^2 - \chi_1^2)^{1/2}$ and isolating its imaginary part, we determine the damping constant (in decibels per unit length of the waveguide)

$$\gamma = \frac{8.6858}{\sqrt{|k_1|^2 - |\chi_1|^2}}\left(\frac{|k_1|^2\operatorname{tg}\Delta_1}{2} + \frac{|\chi_1|^2\Sigma}{\Delta} + \frac{|\chi_1|^2\operatorname{Im}\Omega}{\Delta}\right).$$

The last term in (9) corresponds to the damping introduced by the medium III. For $R \gg \rho$, the value is negligibly small. For a comparative estimate when $\varkappa \ll 1$ we neglect the first two terms of the numerator of (8), the quantities $|u| \ll 1$ and $|\zeta| \ll |\beta|$, and use the approximation $\psi \approx 1 + i\beta$. We then have for a metallic medium

$$\operatorname{Im}\Omega \approx \frac{2\pi\nu|\beta|\varphi_\beta e^{-2|\chi_2|R}}{|\chi_2|\rho(1-|\beta|)^2[K_n(|\chi_2|\rho)]^2}, \tag{10}$$

where φ_ρ is the argument of the complex quantity $\beta = -i|\beta|e^{i\varphi_\beta}$.

If medium III is a dielectric, the largest value in (8) is that of the argument of the complex quantity $e^{i2\chi_2R}$, and

$$\operatorname{Im}\Omega \approx -\frac{4\pi\nu R(\theta^2\varphi_1 + \tau)e^{-2|\chi_2|R}}{\rho(1+|\beta|)[K_n(|\chi_2|\rho)]^2}. \tag{11}$$

Results of numerical calculations. We present the results of numerical calculations for a silver-coated two-layer glass fiber with the following parameters: $\rho = 2.175\ \mu$, $R = 31.1\ \mu$, $n_1 = 1.516$, $n_2 = 1.5025$, tan $\Delta_1 = 6.135\cdot10^{-9}$ (or 400 dB/km) and tan $\Delta_2 = 1.541\cdot10^{-8}$ (or 1000 dB/km). The optical constants of silver $\varepsilon_{Ag} = -16.39$ and $\sigma_{Ag} = 1.273\cdot10^{14}$ (cgs esu) at $\lambda = 0.6328\ \mu$ are determined by linear interpolation between their values at $\lambda = 0.6$ and $0.65\ \mu$, given in ref. 15. The critical parameter of such a fiber is $(2\pi\rho/\lambda)(n_1^2 - n_2^2)^{1/2} = 4.34$; there can exist in this waveguide seven modes propagating in the core and attenuating in the sheath: HE_{11}, H_{01}, E_{01}, HE_{21}, HE_{12}, HE_{31}, and EH_{12}. The attenuation of the HE_{11} wave, calculated from Eqs. (5)-(9), is 426.6 dB/km, of which 25.6 dB/km are due to the second term of (9) and only $3.62\cdot10^{-37}$ dB/km to the third.

The H_{02} mode in such a waveguide has the smallest value of $|\chi_2|$ of all the symmetrical magnetic waves propagating in the sheath, and should therefore have the smallest attenuation. Since $\rho/R \ll 1$ for the design considered by us, this attenuation can be defined as the attenuation of the H_{01} mode in a round metal-optical waveguide filled with one dielectric II [i.e., using Eq. (3) of ref. 1]. It amounts to 1095.5 dB/km, of which 95.5 dB/km is due to the influence of metallic coating III.

If the sheath II of the described fiber is glass having the same loss as the core, i.e., if tan $\Delta_2 = 6.135\cdot10^{-9}$), then the second term of (9) decreases by 1.077 dB/km, so that the total attenuation of the HE_{11} wave is 402.077 dB/km. The damping of the H_{02} mode then decreases to 495.5 dB/km, of which 95.5 dB/km is brought about, as before, by the metallic medium III.

Comparing these results, we can verify at the same time that the metal-optical waveguide filled with a two-layer dielectric operating in the fundamental mode has a much lower attenuation than one filled with dielectric II alone (for the same cross section).

It is of interest to compare the results with the case of an open glass fiber in air. In this case the third term of (9) decreases to $-0.91 \cdot 10^{-39}$ dB/km (at $\tan \Delta_2 = 1.541 \cdot 10^{-8}$).

Thus in both cases, when medium III is metal or air, we obtain so small a value for the attenuation due to this medium that it can be neglected. But then we have no explanation for the experimentally observed 10-15% decrease of the attenuation in a two-layer glass fiber with a thick sheath, after the latter is coated with silver. To understand this phenomenon it is obviously necessary to consider the scattering of the light by the microstructure of the fiber.

EXPERIMENT

Measurement of fiber parameters and fiber metallization. The waveguide is fabricated from two-layer glass fibers of two types, single-mode and multimode.

The core of the single-mode fiber is made of K-3 glass with refractive index 1.5163 and attenuation 0.4 dB/m, while the sheath is made of K-8 glass with refractive index 1.51 and attenuation 1 dB/m. The outer diameter of the fiber is 62.2 m, and the core diameter is 4.35 μ. After preparation of the fiber, the refractive index of its sheath is measured by an immersion method and turns out to be 1.5025. The refractive index of the core remains unchanged at 1.516. It is measured in an experiment in which two fibers of the given type are joined.

To this end, different immersion liquids are placed in the gap (150 μ long) between the fiber end surfaces to be joined, and we plot the dependence of the light-flux transmission coefficient on their refractive indices. This dependence reveals two distinct maxima. The first, smaller in magnitude, corresponds to equality of the refractive indices of the liquid and of the sheath, while the second, larger maximum corresponds to equality of the refractive indices of the liquid and of the core.

In similar fashion we measure the parameters of the multimode fiber: $R = 10.3\ \mu$, $\rho = 9.3\ \mu$, and $\dot{n}_2 = 1.62$.

Chemical silvering of the fiber is affected by the procedure described in ref. 1, in a glass burette 75 cm long. Two thin diaphragms with openings in their centers and with notches on the edges to permit escape of air are placed in the burette.

TABLE 1

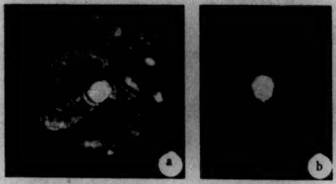

Fig. 2. Planar (a) and conical (b) ends of fibers, obtained by overheating them by passage of electric current through the silver coating.

The quality of the obtained coating is estimated from the value of its running resistance to direct current. For the single-mode fiber, after double silvering the resistance is 5 Ω/cm, while for the multimode fiber the value is 34 Ω/cm.

When the current flowing in the coating exceeds 180-200 mA, the single-mode fiber overheats, and the greatest overheating occurs in the glass dielectric, after which the silver film breaks. The cuts produced in this manner have a rather regular shape. Figure 2 shows photographs of planar and conical cuts (the latter are obtained by slightly stretching the fiber along the axis during the overheating).

To prevent oxidation of the silver coating, it is coated on the outside by asphalt–bitumen lacquer. This increases the fiber diameter, but also increases its strength.

In our experiments, we have investigated fibers with silvered sections that reached 1.4 m in length.

Description of apparatus. The method used by us to measure the damping of the light in the fiber is typical of most investigations on this subject.[16,17] The experimental arrangement is shown in Fig. 3. The light source is a helium–neon laser 1 ($\lambda = 0.6328\ \mu$), the light beam of which is focused on the entrance end of the fiber with the aid of a microobjective 2. The output-power level of the laser is monitored by an FD-1 photodiode placed at the rear mirror.

To eliminate the waves propagating in the sheath the open section of the waveguide is passed through an immersion trap 3. The latter is a glass plate with a drop of immersion liquid having the same refractive index as the sheath.

The exit end of the fiber is placed in front of the objective of microscope 4 with oil immersion. The refractive index of the latter is equal to the refractive index of the core. This choice decreases the scattering of the light flux by the random cleavages and roughnesses of the exit end. In addition, the improved matching of the exit end decreases the reflected backward wave.

Using the eyepiece of the microscope 4, it is possible to observe the structure of the field in the exit section of the waveguide, or to photograph it with the aid of a microphoto attachment. The output flux can be measured by attaching the housing of an FÉU-51 photomultiplier to this eyepiece.

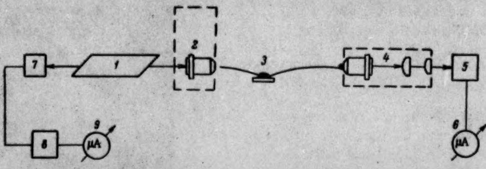

Fig. 3. Experimental arrangement. 1) Laser; 2) excitation source; 3) immersion trap; 4) exit microscope; 5) photomultipliers; 6, 9) microammeters; 7) photodiode; 8) emitter follower.

In the excitation source 2 we use not only an individual microobjective, but a complete reflected-light microscope (MIM-7) from which the illuminator is removed and a laser is placed on the same side as the illuminator. The optical system for excitation of this type was proposed earlier in ref. 16. Using the microscope eyepiece, it is possible to observe simultaneously the entrance end of the fiber and the light beam focused on it. It is easy to align the two accurately, by moving the fiber with the micrometric screws of the object stage of the microscope.

In addition, an arrangement of this type makes it possible to investigate the backward wave produced in the fiber by scattering from its inhomogeneities and by reflection from the mismatched exit end. The polarization of this wave is usually different from the polarization of the direct wave. Therefore, by introducing the analyzer of microscope 2, it is possible to extinguish the image of the direct wave and to observe only the backward wave through the eyepiece.

We present in conclusion Table 1, which lists the values of the neck diameter of the laser-beam caustic and its beam divergence in the focal planes of the various microobjectives. These data are essential in choosing the objective for the excitation of a wave of definite type in the fiber. They are both obtained with the MIM-7 microscope by measuring the diameter of the laser beam reflected from the surface of a glass plate.

Results of the experiment. The investigated fiber, strictly speaking, is not single-mode, since seven modes can exist in it (it would be more correct to call it a "few-mode" fiber). However, when such a fiber is excited by a light beam with a divergence angle 3-4°, only one mode, HE_{11}, is produced in it and propagates at an angle 3°25' to the fiber axis.

Figure 4a shows a photograph of the field distribution in the exit end of an uncoated single-mode fiber, obtained with the excitation described above, while Fig. 4b shows an similar photograph of the same fiber, but coated with silver on the outside. The bright round spot in the center of each of these photographs corresponds to the HE_{11} mode.

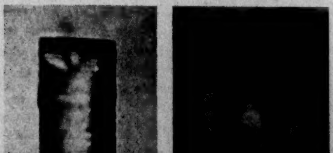

Fig. 4. Light flux at the exit of a single-mode fiber. a) In uncoated construction; b) in metallized construction.

The polarization of the light flux at the exit of the fiber is investigated with the aid of the rotating analyzer of microscope 4 and a compensating quartz wedge. Just as in ref. 17, the results reveal the simultaneous existence at the exit of HE_{11} mode components with plane and elliptic polarizations, and of a depolarized component. The intensity of the latter, however, decreases rapidly with increasing fiber length. In shorter fibers, the higher modes, having different polarizations, come into play, especially the modes propagating in the outer dielectric sheath.

In the present work we noted, in addition, that the character of the polarization of the exit light flux depends on the bends in the single-mode fiber. In practically any section of the latter it is possible to select a bend radius such that the output radiation has either only plane or only elliptic polarization (we have in mind a fiber of sufficient length). This phenomenon is equally well observed in open and metallized single-mode fibers.

This distinguishes the single-mode fiber from the multimode fiber, since the light flux of the latter is completely depolarized. As to the metallized multimode fiber with thin sheath, the number of its output modes is decreased as a result of mode selection by attenuation caused by the presence of the metal. Consequently, the output radiation contains in addition to the depolarized component also components with elliptic and plane polarization.

Figure 5a shows a photograph of the structure of the field in the exit section of a silvered multimode fiber, while Fig. 5b shows a photograph of the same field with the analyzer turned on. The grainy character of this structure is clearly seen on both photographs.

The attenuation of the light flux in the fiber before and after silvering is measured on the same samples by

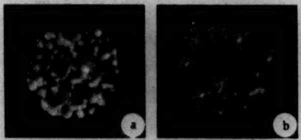

Fig. 5. Light flux at exit from silvered multimode fiber. a) With the analyzer of microscope 4 turned off; b) with the analyzer turned on.

TABLE 2. Attenuation of Light Flux in Fiber (in dB/m)

	Number of sample				
	1	2	3	4	5
Before silvering	1.33	1.9	1.85	2.91	2.91
After silvering	1.16	1.3	1.82	2.76	2.52

cutting off individual sections and determining the resultant changes of the output signal (at equal excitation conditions). To exclude the effect of a random cleaved surface on the exit end, the measurements are repeated on several cuts separated by 0.5-1 mm. The results of these measurements, averaged over 5-10 closely located cuts, are given in Table 2.

The obtained values of the attenuation exceed somewhat the calculated ones (for the HE_{11} mode). This is obviously due to the imperfect technology of fiber preparation, wherein the number of inhomogeneities in the fiber is greatly increased. In addition, a role is played by the presence of additional "waveguide scattering" of the light flux by the roughnesses of the boundaries.[18]

For a more exact determination of the difference between the attenuation in the fiber before and after silvering, we use also a differential method. We measure first the light flux at the exit from a fiber with a silvered section 1.4 m long. The silver film is then removed with nitric acid within several seconds, and the change of the output signal is recorded.

The measurements are performed on two samples of a single-mode fiber. For the first of them we obtain a 5.5% decrease of the output signal within 30 seconds after pouring the acid into the cell with the fiber, and another 16% decrease during the subsequent 3.5 minutes. When converted into running attenuation in the metallized section, this amounts to 0.18 and 0.48 dB/m, respectively. For the second sample, we obtain a 7% decrease of the signal within the first 30 seconds and another 4% after the next 30 seconds (0.21 and 0.13 dB/m). The initial increments are obviously due to the removal of the silver film, while those succeeding them (in time) are due to the damage of the glass fiber by the acid, which absorbs the metallic impurities and leaves, therefore, pores and cracks.

The attenuation in a multimode fiber is measured only by cutting off the measured sections (approximately 10 cm long). It is observed there that the attenuation is increased by silvering from 5-7 to 16-20 dB/m.

Comparing the obtained data, we can easily note a significant difference between the single-mode and multimode fibers. Whereas silvering the former reduces the attenuation by 10-15%, silvering the latter, to the contrary, increases the attenuation.

This is obviously due to the difference in the thickness of the sheath. In a single-mode fiber with a thick sheath, the loss introduced by the metal is smaller than the fraction of the scattered light reflected by the specularly reflecting metallic layer and returns to the HE_{11} wave via mode transformation by the inhomogeneities (in an uncoated fiber, this energy is radiated to the outside within the limits of the critical angle on the sheath–air interface and by scattering from the inhomogeneities of this interface). In a multimode fiber with a thin sheath, the losses caused by the metal exceed the energy returned by the metal, so that the attenuation is larger.

The observed decrease of the attenuation upon metallization of a fiber with a thick sheath is, of course, also of practical importance. As is well known, an uncoated single-mode fiber with an attenuation of 16 dB/km has been produced,[18] as well as a multimode fiber[19] with attenuation 2 dB/km. It is quite probable that owing to the lower losses to the absorption, the silvering of such a fiber would result in an even larger decrease of the attenuation than is observed in our case. This would be of great importance, since the already attained attenuations are close to the limits imposed by Rayleigh scattering in glass and by the "waveguide scattering" from the roughnesses of the boundaries.[18,20]

Of course, the designs investigated here do not exhaust all the possible variants of round metal-optical waveguides with two-layer dielectrics. To decrease the Rayleigh scattering in the core it is possible, for example, to replace it by a metallized quartz or glass capillary filled with liquid. It is reported in ref. 21 that glass capillaries filled with hexachlorbutadiene have been produced and have an attenuation of 6 dB/km. One can hope that the silvering of such capillaries will also decrease their attenuation.

The metallization of a dielectric waveguide transforms it into a covered metallic waveguide, one of the most significant advantages of which is the absence of spurious emission. In addition, metallization makes possible a certain decrease in the dielectric-sheath thickness without increasing the waveguide attenuation, so that the number of channels per unit cross section area of the cable can be increased.

CONCLUSION

We have shown that the designs considered here combine successfully the useful properties of dielectric and metallic waveguides. On the one hand, if the sheath is thick enough, the scattering of the light by the inhomogeneities of the metal–glass interface is greatly decreased; on the other hand, the presence of the metallic layer eliminates spurious emission from the fiber and decreases the attenuation.

The properties described above enable us to use the considered waveguide in optical-signal transmission systems and in optoelectronics.

Excitation of Alfvén waves in decay instabilities

A. G. Elfimov and F. M. Nekrasov

(Submitted January 17, 1973)
Zh. Tekh. Fiz., 44, 16–21 (January 1974)

The evolution of the wave numbers is studied for Alfvén waves transverse to a constant magnetic field. These waves are excited by the decay instability of a standing magnetoacoustic wave. It is shown that finite conductivity stabilizes the spectrum. The time required to establish a stationary spectrum is determined and the profile of the spectrum is found. Criteria are obtained for the stability of the Alfvén wave as a function of the plasma parameters and the amplitude of the pump wave. It is shown that there is no transfer of energy through the spectrum for a traveling pump wave.

The system of equations that describes the stability of characteristic magnetohydrodynamic oscillations of a plasma in the field of a pump wave has the form (see, for example, ref. 1)

$$\frac{d^2X^{\alpha}_{m}}{dt^2}+\Omega^2_{m,\alpha}X^{\alpha}_{m}=h_0\sum_{\alpha',m'}U^{\alpha\alpha'}_{mm'}X^{\alpha'}_{m'}, \tag{1}$$

where the $\Omega_{m,\alpha}$ are the characteristic frequencies of the linear oscillations of the plasma. The field of the pump wave is assumed to be weak, and its coordinate–time dependence is given by

$$\mathbf{H}^{(0)}(x,\ t)=h_0\sum_{m,n}\mathbf{A}_{m,n}\exp i(mk_0x+n\Omega_0t), \tag{2}$$

where k_0 and Ω_0 are related by the linear dispersion relation; h_0 is a dimensionless small parameter, and the matrix elements $U^{\alpha\alpha'}_{mm'}$ are periodic functions of the time, with period $2\pi\Omega_0^{-1}$. The dependence of the perturbations on the coordinate $\varkappa$ is represented, as usual, in the form

$$X^{\alpha}(x;\ t)=\sum_m X^{\alpha}_m(t)\exp i\varkappa_m x, \tag{3}$$

where $\varkappa_m = \varkappa + mk_0$. The indices of the Fourier transform with respect to the coordinates y and z are omitted. Throughout this paper, in discussing a spectral distribution we have in mind the distribution associated with the x coordinate.

A typical decay instability consists of the excitation of two normal modes $X^{\alpha_1}_{m_1}$ and $X^{\alpha_2}_{m_2}$, for which the so-called decay conditions are satisfied; these relate the characteristic frequencies and wave vectors of these modes to the corresponding characteristics of the pump wave.[2] The instability is excited by the transfer of energy from the pump wave to these oscillations.

A different situation obtains when the frequencies $\Omega_{m\alpha}$ do not depend or depend weakly on the subscript m (there is no dispersion or the dispersion is weak in the direction of the inhomogeneity of the pump wave). In this case, the decay condition for the frequencies

$$|\Omega_0|=|\Omega_{m,\alpha_1}|+|\Omega_{m,\alpha_2}| \tag{4}$$

is satisfied for all m_1 and m_2. There are now not two, but infinitely many spatial harmonics characterized by α_1 and α_2. One has the problem of the time behavior of the m spectrum of unstable amplitudes and the dependence of this behavior on the initial conditions.

We have considered this problem for Alfvén waves in a plasma in the presence of a magnetoacoustic pump wave. In papers[3–5] on the excitation of Alfvén waves by magnetoacoustic waves with which we are acquainted, the behavior of the spectrum has not been investigated.

The problem is solved using the equations of magnetohydrodynamics:

$$\left.\begin{aligned}\rho\left\{\frac{\partial V}{\partial t}+(\mathbf{V}\nabla)\mathbf{V}\right\}&=-\operatorname{grad}\left(P+\frac{\mathbf{H}^2}{8\pi}\right)+\frac{1}{4\pi}(\mathbf{H}\nabla)\mathbf{H},\\ \frac{\partial\rho}{\partial t}+\operatorname{div}\rho\mathbf{V}&=0;\quad P=P_0\left(\frac{\rho}{\rho_0}\right)^{\gamma},\\ \frac{\partial\mathbf{H}}{\partial t}&=\operatorname{curl}[\mathbf{VH}]+\frac{c^2}{4\pi\sigma}\nabla^2\mathbf{H}.\end{aligned}\right\} \tag{5}$$

The notation is customary. Effects associated with dissipation are assumed to be weak and are taken into account in the same way as in ref. 1 only in the investigation of the perturbations. The small parameter h_0 is the ratio of the amplitude of the field of the magnetoacoustic wave to H_0, the constant magnetic field. The problem is solved in the linear approximation in this parameter.

In the stationary state $[\partial/(\partial y) = \partial/(\partial z) = 0]$, the field and plasma are described by the relations

$$\left.\begin{aligned}H_z^{(0)}(x;\ t)&=H_0(1+h_0\cos k_0x\sin\Omega_0t),\\ v_x^{(0)}(x;\ t)&=-\frac{\Omega_0}{k_0}h_0\sin k_0x\cos\Omega_0t\\ \rho^{(0)}(x;\ t)&=\rho_0(1+h_0\cos k_0x\sin\Omega_0t),\\ P^{(0)}(x;\ t)&=P_0(1+\gamma h_0\cos k_0x\sin\Omega_0t),\\ \Omega_0^2=k_0^2(c_s^2+c_A^2);\ c_A^2&=\frac{H_0^2}{4\pi\rho_0};\quad c_s^2=\gamma\frac{P_0}{\rho_0}.\end{aligned}\right\} \tag{6}$$

In solving the perturbation problem we assume $\partial/\partial y = 0$. This simplifies the solution since it allows separation of the Alfvén branch from the magnetoacoustic branch. The equation that describes the Alfvén wave reduces to the equation for the y component of the velocity perturbation:

$$\begin{aligned}\frac{\partial^2v_y}{\partial t^2}+k_z^2c_A^2v_y&=-\frac{c^2}{4\pi\sigma}\left(k_z^2-\frac{\partial^2}{\partial x^2}\right)\frac{\partial v_y}{\partial t}\\ &+h_0\left[\frac{\Omega_0}{k_0}\sin k_0x\left(2\cos\Omega_0t\frac{\partial^2v_y}{\partial x\partial t}-\Omega_0\sin\Omega_0t\frac{\partial v_y}{\partial x}\right.\right.\\ &\left.\left.-\cos k_0x\left(k_z^2c_A^2\sin\Omega_0tv_y-\Omega_0\cos\Omega_0t\frac{\partial v_y}{\partial t}\right)\right)\right].\end{aligned} \tag{7}$$

The smallness of the dissipative effects assumed in this paper corresponds to the condition

$$h_0^2\ll\frac{c^2}{4\pi\sigma\Omega_0l^2_{\min}}\ll1, \tag{8}$$

where $l_{\min}$ is the minimum spatial scale of the problem.

Representing the solution in the form (3), we can reduce Eq. (7) to a system like (1) with frequency $\Omega^2_{m\alpha} = k_z^2 C_A^2$, which does not depend on m. However, it is more convenient to solve Eq. (7) directly and then to expand the solution in plane waves which are eigenfunctions for planar geometry.

The solution of Eq. (7) is based on Bogolyubov's idea of multiple time scales.[6] The method of solving the problem adopted here, which uses this idea, is described, for example, in ref. 7 and the literature cited there. To solve the problem we expand the desired function and the time derivatives in powers of the small parameter:

$$v_y = v_y^{(0)} + h_0 v_y^{(1)} + \ldots; \quad \frac{\partial}{\partial t} = \frac{\partial}{\partial t_0} + h_0 \frac{\partial}{\partial t_1} + \ldots; \tag{9}$$

where $t_0 \equiv t$, $t_1 \equiv h_0 t$, etc., substitute these expansions into the equation, and equate terms of equal powers of h_0. An important requirement is that there be no secular terms in the solution.

Let us first investigate Eq. (7) with zero dissipation. Our method leads to the following equations: The zeroth approximation is

$$\frac{\partial^2 v_y^{(0)}}{\partial t_0^2} + \frac{\Omega_0^2}{4} v_y^{(0)} = 0. \tag{10}$$

The first approximation is

$$\frac{\partial^2 v_y^{(1)}}{\partial t_0^2} + \frac{\Omega_0^2}{4} v_y^{(1)} + 2\frac{\partial^2 v_y^{(0)}}{\partial t_0 \partial t_1} = \frac{\Omega_0}{k_0} \sin k_0 x v_y^{(0)}$$
$$\times \left(2 \cos \Omega_0 t_0 \frac{\partial^2 v_y^{(0)}}{\partial x \partial t_0} - \Omega_0 \sin \Omega_0 t_0 \frac{\partial v_y^{(0)}}{\partial x}\right)$$
$$- \cos k_0 x \left(\frac{\Omega_0^2}{4} \sin \Omega_0 t_0 v_y^{(0)} - \Omega_0 \cos \Omega_0 t_0 \frac{\partial v_y^{(0)}}{\partial t_0}\right). \tag{11}$$

For simplicity, in Eqs. (10) and (11) we have used the condition of exact resonance $\Omega_0 = 2|k_z c_A|$. Substituting the solution

$$v_y^{(0)} = A(x;\ t_1) \cos \frac{1}{2} \Omega_0 t_0 + B(x;\ t_1) \sin \frac{1}{2} \Omega_0 t_0 \tag{12}$$

of Eq. (10) into Eq. (11) and using the condition that there are no secular terms in $v_y^{(1)}$ [vanishing of the coefficients of $\sin(1/2)\Omega_0 t_0$ and $\cos(1/2)\Omega_0 t_0$], we obtain

$$\frac{\partial A}{\partial t_1} = -\frac{\Omega_0}{8} \cos k_0 x A, \tag{13}$$

$$\frac{\partial B}{\partial t_1} = \frac{\Omega_0}{8} \cos k_0 x B, \tag{14}$$

$$\frac{\partial^2 v_y^{(1)}}{\partial t_0^2} + \frac{\Omega_0^2}{4} v_y^{(1)} = \Omega_0^2 \Big[\cos \frac{3}{2} \Omega_0 t_0 \Big(\frac{1}{k_0} \frac{\partial B}{\partial x} \sin k_0 x + \frac{3}{8} B \cos k_0 x\Big)$$
$$- \sin \frac{3}{2} \Omega_0 t_0 \Big(\frac{1}{k_0} \frac{\partial A}{\partial x} \sin k_0 x + \frac{3}{8} A \cos k_0 x\Big)\Big]. \tag{15}$$

The complete dependence $v_y^{(1)}$ on the slow time t_1 is determined by the equations of the higher approximation. Its determination goes beyond the limits determined by the accuracy of the present paper. Since the first approximation is a small correction to the solution of the zeroth approximation, we shall restrict ourselves in what follows to studying the dependence of the zeroth approximation on the slow time. Thus,

$$v_y \simeq v_y^{(0)} = A(x) \exp\Big(-\frac{h_0}{8} \Omega_0 t \cos k_0 x\Big) \cos \frac{1}{2} \Omega_0 t$$
$$+ B(x) \exp\Big(\frac{1}{8} h_0 \Omega_0 t \cos k_0 x\Big) \sin \frac{1}{2} \Omega_0 t. \tag{16}$$

The form of the functions A and B is determined by the initial and boundary conditions for v_y. It follows from (16) that the initial profile of the perturbation is strongly distorted with the course of time. A characteristic feature is the formation of peaks at the points $k_0 x = \pm n\pi$, with a height that increases with the time, the width being a decreasing function.

To describe the behavior of the perturbation in terms of spectral characteristics we must represent the solution (16) in the form

$$\left.\begin{aligned} v_y^{(0)} &= \sum_{s=-\infty}^{\infty} u_s \exp isk_0 x, \\ u_s &= \sum_n I_n\Big(\frac{h_0}{8} \Omega_0 t\Big)\Big[(-1)^n A_{s-n} \cos \frac{1}{2} \Omega_0 t + B_{s-n} \sin \frac{1}{2} \Omega_0 t\Big], \end{aligned}\right\} \tag{17}$$

where the I_n are modified Bessel functions and A_m and B_m are the Fourier coefficients of the expansions of the functions A(x) and B(x). To be specific, in deriving (17) we assume that the boundary conditions require periodicity of the solution with period $L = 2\pi/k_0$. An important characteristic associated with the spectral energy density is $|u_s|^2$ (averaging is performed over the period of the Alfvén oscillations). This quantity is

$$\overline{|u_s|^2} = \frac{1}{2} \sum_{n,n'} I_n\Big(\frac{1}{8} h_0 \Omega_0 t\Big) I_{n'}\Big(\frac{1}{8} h_0 \Omega_0 t\Big)$$
$$\times [(-1)^{n+n'} A_{s-n} A^*_{s-n'} + B_{s-n} B^*_{s-n'}]. \tag{18}$$

Bearing in mind that the main contribution in the sum in (18) is determined by the region $|n|, |n'| \lessdot (1/8) h_0 \Omega_0 t$, and also remembering that the asymptotic behavior of the modified Bessel functions depends weakly on the index, we can write Eq. (18) as

$$\overline{|u_s|^2} \simeq \frac{1}{2} I_0^2\Big(h_0 \frac{\Omega_0 t}{8}\Big) \sum_{m,\, m'=s-N}^{s+N} [(-1)^{m+m'} A_m A^*_{m'} + B_m B^*_{m'}], \tag{19}$$

where N is the integral part of $h_0 \Omega_0 t/8$. Thus, if a narrow spectrum of oscillations is excited at the initial time in the region $|m| \sim m_0$, the spectrum broadens with time. The width of the spectrum Δm_0 is determined roughly by the condition

$$\Delta m_0 \sim \frac{1}{8} h_0 \Omega_0 t. \tag{20}$$

But if the initial spectrum is broad, the spectral density of the energy will be determined in the course of time by an ever broader section of the spectrum of initial perturbations. The time dependence of the width of the spectrum (20) can also be found from the general form of the solution. It is sufficient to represent $\exp[(h_0 \Omega_0 t/8) \cos k_0 x]$ as a series and then the time of excitation of the harmonic m is determined approximately by

$$\frac{1}{m!}\Big(\frac{h_0 \Omega_0 t}{8}\Big)^m \sim 1. \tag{21}$$

From (17) one can determine the variation of the mean square of the velocity perturbation v_y^2 in the case of a random distribution of the phases of the initial perturbation:

$$\overline{v_y^2}=\sum_s\overline{|u_s|^2}=\frac{1}{2}I_0\left(\frac{h_0\Omega_0t}{4}\right)\sum_m(|A_m|^2+|B_m|^2). \tag{22}$$

It is to be expected that when allowance is made for the finite conductivity, the broadening of the spectrum due to the excitation of ever higher modes will be restricted. With dissipation Eqs. (14) and (15) are replaced by

$$\left.\begin{aligned}\frac{\partial A}{\partial t_1}+\frac{\Omega_0}{8}\cos k_0xA+\frac{c^2}{8\pi\sigma h_0}\left(k_z^2A-\frac{\partial^2A}{\partial x^2}\right)=0,\\ \frac{\partial B}{\partial t_1}-\frac{\Omega_0}{8}\cos k_0xB+\frac{c^2}{8\pi\sigma h_0}\left(k_z^2B-\frac{\partial^2B}{\partial x^2}\right)=0.\end{aligned}\right\} \tag{23}$$

It is easy to show that a solution of these equations satisfying the previously mentioned periodicity condition in the x coordinate has the form

$$\left.\begin{aligned}A=\sum_{m=0}^{\infty}\Big\{A_m^{(1)}\exp(-\alpha_m\Omega_0t)\,ce_{2m}\left(\frac{k_0x}{2};\ q\right)\\ +A_m^{(2)}\exp(-\beta_m\Omega_0t)\,se_{2m+2}\left(\frac{k_0x}{2};\ q\right)\Big\},\\ B=\sum_{m=0}^{\infty}\Big\{B_m^{(1)}\exp(-\alpha_m\Omega_0t)\,ce_{2m}\left(\frac{k_0x}{2};\ -q\right)\\ +B_m^{(2)}\exp(-\beta_m\Omega_0t)\,se_{2m+2}\left(\frac{k_0x}{2};\ -q\right)\Big\},\end{aligned}\right| \tag{24}$$

where $q = 2\pi\sigma\Omega_0h_0(k_0c)^{-2}$.

In Eq. (24), ce_{2m} and se_{2m+2} are Mathieu functions,[8] and the constants $A_m^{(1,2)}$ and $B_m^{(1,2)}$ are determined by the initial conditions. The characteristic exponents α_m and β_m are related to the eigenvalues $\alpha_{2m}(q)$ and $b_{2m+2}(q)$ of the functions $ce_{2m}(k_0x/2;\ q)$ and $se_{2m+2}(k_0x/2;\ q)$ by

$$\alpha_m=\frac{k_0^2c^2}{32\pi\sigma\Omega_0}\left(a_{2m}+1+\frac{c_s^2}{c_A^2}\right);\ \ \beta_m=\frac{k_0^2c^2}{32\pi\sigma\Omega_0}\left(b_{2m+2}+1+\frac{c_s^2}{c_A^2}\right). \tag{25}$$

In Eq. (25) we have used the resonance condition $4k_z^2c_A^2=k_0^2(c_A^2+c_s^2)$. For fixed q, the eigenvalues a_{2m} and b_{2m+2} form an infinite uniformly increasing sequence $a_0 < b_2 < a_2 < b_4 < \ldots$, and $a_0 \leq 0$ for all $|q|$, while b_2 changes sign in the region of $|q| \sim 8$. More detailed data can be obtained from the monograph in ref. 8. The asymptotic behavior of the solution (24) will be determined by the smallest eigenvalue. If the initial and boundary conditions are such that $A_0^{(1)}$ or $B_0^{(1)}$ in the expansion (24) are nonzero, a_0 is the eigenvalue. In this case, the instability condition is

$$a_0+1+\frac{c_s^2}{c_A^2}<0. \tag{26}$$

Taking account of the dependence $a_0(q)$ (see Appendix 2 in ref. 8, in which the data are rounded off with accuracy 10%) for $c_s^2/c_A^2 \ll 1$, we obtain

$$h_0>\frac{3k_0^2c^2}{4\pi\sigma\Omega_0}. \tag{27}$$

But if the initial and boundary conditions are such that $A_0^{(1)} = 0$ and $B_0^{(1)} = 0$ in the expansion (24) and $A_0^{(2)}$ or $B_0^{(2)}$ are nonvanishing, the asymptotic behavior will be determined by b_2 and the instability condition analogous to (27) has the form

$$h_0>\frac{27}{2}\frac{k_0^2c^2}{4\pi\sigma\Omega_0}. \tag{28}$$

An exact analysis of the transient processes described by Eq. (24) for arbitrarily specified initial conditions is fairly complicated. However, the asymptotic form of the perturbation will be described either by the function $ce_0(k_0x/2;\pm q)$ or $se_2(k_0x/2;\pm q)$. The time required to reach the asymptotic regime t_a is determined in these two cases by the conditions

$$\left.\begin{aligned}\left|t_a\frac{k_0^2c^2}{32\pi\sigma}\left[a_0(q)+1+\frac{c_s^2}{c_A^2}\right]\right|\sim 1,\\ \left|t_a\frac{k_0^2c^2}{32\pi\sigma}\left[b_2(q)+1+\frac{c_s^2}{c_A^2}\right]\right|\sim 1.\end{aligned}\right\} \tag{29}$$

Thus, allowance for dissipation leads, in contrast to (15), to a stationary form of the perturbation. The functions ce_0 and se_2 are also characterized by the presence of peaks, but their width remains finite in contrast to the function $(1/8h_0\Omega_0t\,\cos k_0x)$, for which the width of the peaks decreases with the time.

Comparing the two solutions (15) and (24) we obtain the following picture for the development of longwave perturbations. As long as dissipation is weak, energy is transferred to the shortwave part of the spectrum, the amplitudes increasing at the same time. With the excitation of high harmonics, for which damping is important, the profile of the spectrum begins to be stabilized and after the passage of time determined by Eq. (29) a stationary spectral profile is established.

It should be noted that the transfer of energy through the spectrum does not occur in the presence of a traveling wave above.

The general solution without dissipation has the form

$$A=\cos k_0x\left[\varphi_1(x)\exp\left(-\frac{1}{8}h_0\Omega_0t\right)+\varphi_2(x)\exp\left(\frac{1}{8}h_0\Omega_0t\right)\right],$$

$$B=(1-\sin k_0x)\,\varphi_2(x)\exp\left(\frac{1}{8}h_0\Omega_0t\right)$$

$$-(1+\sin k_0x)\,\varphi_1(x)\exp\left(-\frac{1}{8}h_0\Omega_0t\right).$$

The energy transfer to the shortwave part of the spectrum considered for an Alfvén wave can also occur for ion-acoustic waves when $c_s^2/c_A^2 \lessdot h_0$. This effect can play an appreciable role in the rf heating of a plasma.

(Submitted February 2, 1973)
Zh. Tekh. Fiz., 44, 22-27 (January 1974)

Frequency spectra are given for waves emitted from a plane plasma layer at a finite temperature in the absence of an external magnetic field. As a result of the energy loss by radiation the frequencies are complex and this means that the waves are damped in the layer. This damping must be taken into account together with the other loss mechanisms in any study of the propagation and interaction of waves in bounded plasma systems.

1. INTRODUCTION

It is well known that the fact that a plasma is bounded leads to a series of specific properties connected with the propagation of waves: discrete frequency spectrum for the natural modes of the system and the possibility of surface waves.

It is also important that bounded plasma systems can produce oscillations with a finite lifetime, so that in addition to a real frequency spectrum there is also a spectrum with complex values of ω. This is because a bounded system, in contrast to an unbounded one, can lose energy by radiation. The oscillations which correspond to the radiated modes are damped in time and this increases the effective wave dissipation in the system.

Radiated modes were first found by Dawson and Oberman[1,2] for a plasma cylinder in a strong magnetic field. The general conditions for the existence of radiated modes were derived in refs. 3 and 4 for bounded plasma systems and the radiation mechanism was related to the Cerenkov effect. For radiation into a vacuum it is essential that the projection of the phase velocity of the wave on the plasma–vacuum surface exceed the velocity of light in vacuum ($\omega/k_{\parallel} > c$, where $k_{\parallel}$ is the projection of the wave vector onto the plasma–vacuum boundary).

In the present paper we derive the spectra of TE and TM waves emitted from a plane plasma layer of finite temperature in the absence of an external magnetic field. The radiation from a layer of cold plasma with $(\omega_p/c)a \gg 1$ (ω_p is the electron plasma frequency and a is the layer width) has been considered in ref. 5. We consider the radiation by studying the nonlinear wave interaction in the plasma layer.

2. STATEMENT OF THE PROBLEM

In order to investigate the high-frequency spectrum of oscillations in a plane isotropic plasma layer we make use of the usual system of linearized hydrodynamic equations for the electrons and consider the ions to be fixed (see, for example, ref. 6):

$$\left.\begin{aligned} n_0\frac{\partial \mathbf{v}}{\partial t}+\frac{en_0}{m}\mathbf{E}+s^2\nabla n&=0,\\ \frac{\partial n}{\partial t}+\operatorname{div} n_0\mathbf{v}&=0,\\ \frac{\partial \mathbf{H}}{\partial t}+c\operatorname{curl}\mathbf{E}&=0,\\ \frac{\partial \mathbf{E}}{\partial t}-c\operatorname{curl}\mathbf{H}-4\pi en_0\mathbf{v}&=0.\end{aligned}\right\}\qquad(1)$$

Here, $s = [\gamma(T/m)]^{1/2}$ is the velocity of sound and n_0 is the equilibrium plasma density. The remaining notation is standard.

We take the x axis to be perpendicular to the plasma layer and assume that the plasma is bounded by the planes $x = -a, a$. The system (1) must be supplemented by the boundary conditions at the plasma–vacuum boundary and at infinity. We assume that at the plasma–vacuum boundary the electrons undergo perfect reflection. In addition, the tangential components of the electric and magnetic fields are continuous at this boundary. At infinity we impose the condition that there be no incoming waves.

We further assume that the waves propagate in the x, y plane, i.e., $k_z = 0$. Since the system is linear and homogeneous in y, the variation of the disturbance with time and with the coordinate y can be taken in the form $\exp\{-i\omega t + ik_y y\}$.

The system (1) can then be reduced to the three equations

$$\frac{d^2\Psi_i}{dx^2}+\left(\frac{\omega^2-\omega_{pe}^2}{c_i^2}-k_y^2\right)\Psi_i=0,$$

$$\Psi_1=E_z,\ \Psi_2=H_z,\ \Psi_3=n,\ c_1=c_2=c,\ c_3=s.\qquad(2)$$

The other variables can be expressed in terms of E_z and H_z as follows:

$$v_z=-\frac{i}{\omega}\frac{e}{m}E_z,\ H_x=\frac{k_yc}{\omega}E_z,\ H_y=-\frac{ic}{\omega}\frac{\partial E_z}{\partial x},\qquad(3)$$

$$\left.\begin{aligned} v_x&=-i\frac{e}{m}\frac{ck_y}{\omega^2-\omega_{pe}^2}H_z-i\frac{s^2}{n^0}\frac{\omega}{\omega^2-\omega_{pe}^2}\frac{\partial n}{\partial x},\\ v_y&=-\frac{e}{m}\frac{c}{\omega^2-\omega_{pe}^2}\frac{\partial H_z}{\partial x}+\frac{s^2}{n_0}\frac{k_y\omega}{\omega^2-\omega_{pe}^2}n,\\ E_x&=-\frac{\omega ck_y}{\omega^2-\omega_{pe}^2}H_z+\frac{4\pi es^2}{\omega^2-\omega_{pe}^2}\frac{\partial n}{\partial x},\\ E_y&=-i\frac{c\omega}{\omega^2-\omega_{pe}^2}\frac{\partial H_z}{\partial x}+i\frac{4\pi es^2k_y}{\omega^2-\omega_{pe}^2}n.\end{aligned}\right\}\qquad(4)$$

The relation between the longitudinal and transverse oscillations is established through the boundary conditions. In a plane plasma layer there can be independent propagation of TE waves, in which the electric field vector is perpendicular to the plane of incidence, and TM waves, in which the magnetic field vector is perpendicular to this plane.

The problem can be stated as follows: For given k_y, given temperature and plasma density, find the spectrum of values of ω for which the solutions of (2) satisfy the boundary conditions.

3. EMISSION OF TE WAVES FROM A PLASMA LAYER

We start with the simple case of the emission of TE waves from a plasma layer. Inside the layer the waves are described by the equation

$$\frac{d^2E_z}{dx^2} + \left(\frac{\omega^2 - \omega_{pe}^2}{c^2} - k_y^2\right)E_z = 0 \tag{5}$$

and by the boundary continuity conditions

$$\{E_z\}_{x=\pm a} = 0, \quad \left\{\frac{d}{dx}E_z\right\}_{x=\pm a} = 0.$$

The waves in vacuum are described by (5) with $\omega_{pe} = 0$.

We introduce the following notation:

$$k^2 \equiv \frac{\omega^2 - \omega_{pe}^2}{c^2} - k_y^2, \quad \varkappa^2 \equiv \frac{\omega^2}{c^2} - k_y^2. \tag{6}$$

In accordance with the radiation condition at infinity we assume that in the vacuum where $x < -a$ the solution varies as $\sim \exp\{-i\varkappa x\}$ and that when $x > a$ the solution goes as $\sim \exp\{i\varkappa x\}$, where we take $\mathrm{Re}\,\varkappa > 0$. It can easily be shown that the solutions of (5) which satisfy the boundary conditions can be divided into those which are even and those which are odd with respect to the x coordinate.

For even solutions of E_z the spectrum of allowed values for ω can be found with the help of (6) from the dispersion equation

$$\operatorname{tg} ka = -\frac{i\varkappa}{k}. \tag{7}$$

For odd solutions of E_z the dispersion equation takes the form

$$\operatorname{tg} ka = -\frac{ik}{\varkappa}. \tag{8}$$

Equations (7) and (8) do not have purely real or imaginary solutions for ω. They are most easily solved in terms of the unknown ka. Using (6), we write (7) and (8) in the form

$$\operatorname{tg} ka = -i\sqrt{1 + \frac{\alpha_0^2}{(ka)^2}}, \tag{9}$$

$$\operatorname{tg} ka = -\frac{i}{\sqrt{1 + \frac{\alpha_0^2}{(ka)^2}}}, \tag{10}$$

where $\alpha_0^2 = (\omega_{pe}^2 a^2)/c^2$.

We put $ka = k_r + ik_i$. The solutions (9) and (10) satisfy $k_r > 0$, $k_i < 0$. These solutions can easily be found graphically. Numerical calculations give the variation of k_r and $|k_i|$ with α_0 shown in Fig. 1 for (9) and in Fig. 2 for (10). The asymptotic values of k_r and k_i for $\alpha_0 \gg 1$ can easily be obtained from (9) and (10).

It follows from (9) that when $\alpha_0 \gg |ka|$, $\cot ka \approx 0$, and so $ka \approx (\nu + 1/2)\pi$. In a similar way from (10) we get $ka \approx \nu\pi$. The correction terms can be found by successive approximations. Thus we obtain

$$\left.\begin{aligned} &k_r + ik_i \approx \left(\nu + \tfrac{1}{2}\right)\pi - \frac{\left(\nu + \frac{1}{2}\right)\pi}{\alpha_0^2} - i\,\frac{\left(\nu + \frac{1}{2}\right)\pi}{\alpha_0}, \\ &\nu = 0, 1, 2, \ldots, \ \alpha_0 \gg \left(\nu + \tfrac{1}{2}\right)\pi \end{aligned}\right\} \tag{11}$$

for even solutions,

$$\left.\begin{aligned} &k_r + ik_i \approx \nu\pi - \frac{\nu\pi}{\alpha_0^2} - i\,\frac{\nu\pi}{\alpha_0}, \\ &\nu = 1, 2, \ldots, \ \alpha_0 \gg \nu\pi \end{aligned}\right\} \tag{12}$$

for odd solutions.

It is easy to find the values of ω from (6). When $\alpha_0 \gg \nu\pi$ we get

$$\left.\begin{aligned} &\mathrm{Re}\,\omega_\nu \approx \sqrt{\omega_p^2 + k_y^2c^2 + k_r^2\frac{c^2}{a^2}}, \\ &\mathrm{Im}\,\omega_\nu \approx -\frac{k_r^2c^2}{\alpha_0 a^2}\frac{1}{\mathrm{Re}\,\omega_\nu}, \quad \nu = 0, 1, 2, 3, \ldots \end{aligned}\right\} \tag{13}$$

where k_r is given by (11) or (12).

As expected, the damping disappears in an unbounded plasma when $\alpha_0 \to \infty$ and the frequency spectrum becomes continuous. The value of $\mathrm{Re}\,ka$ corresponding to the highest mode is closer to the appropriate asymptote. This is connected with the fact that the wavelength decreases for high k values and for the highest mode ν the approximation to an unbounded plasma is more closely satisfied.

4. EMISSION OF TM WAVES FROM A PLASMA LAYER

We first consider a cold plasma ($\beta^2 = s^2/c^2 = 0$). For TM waves we have the equation

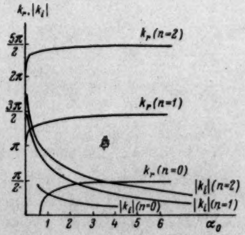

Fig. 1. Spectrum of values of ka for symmetric TE modes.

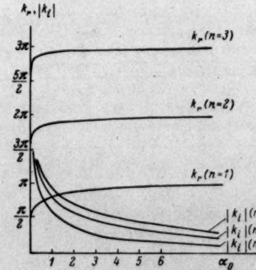

Fig. 2. Spectrum of values of ka for antisymmetric TE modes.

$$\frac{d^2H_z}{dx^2}+\left(\frac{\omega^2-\omega_{pe}^2}{c^2}-k_y^2\right)H_z=0$$

(for the vacuum $\omega_{pe} = 0$).

The tangential components of the fields E_y and H_z, i.e., H_z and $(1/\varepsilon)(dH_z/dx)$, are continuous at the plasma–vacuum boundary. Thus, for the even (symmetric) solutions of H_z we get the dispersion equation

$$\operatorname{tg} ka=-\frac{i\varkappa}{k}\varepsilon, \tag{14}$$

and for the odd (antisymmetric) solution

$$\operatorname{ctg} ka=\frac{i\varkappa}{k}\varepsilon. \tag{15}$$

Here, as before, k^2 and $\varkappa^2$ are defined by (6) and $\varepsilon = 1 - (\omega_{pe}^2/\omega^2)$. It follows from (6) that ε can be represented in the form

$$\varepsilon=\frac{k^2+k_y^2}{\varkappa^2+k_y^2}.$$

The solutions of (14) and (15) now depend not only on the parameter α_0, but also on k_y. In the two limiting cases $k_y^2 \gg \operatorname{Re}\varkappa^2$ and $k_y^2 \ll \operatorname{Re}\varkappa^2$ the roots of (14) and (15) are close to those already found (see Figs. 1 and 2) except that in the second case the roots for the symmetric and antisymmetric modes are interchanged. In the wide layer approximation $\alpha_0 \gg 1$, the dispersion of symmetric TM waves emitted from the plasma can be found from (13) and the following asymptotic equations:

$$ka\approx\nu\pi-\frac{\nu\pi}{\alpha_0}\left(1+\frac{k_y^2a^2}{\nu^2\pi^2}\right)\left(\frac{1}{\alpha_0}+i\right),\quad \text{if}\quad k_y^2\gg\operatorname{Re}\varkappa^2$$

$$ka\approx\left(\nu+\frac{1}{2}\right)\pi-\frac{\left(\nu+\frac{1}{2}\right)\pi}{\alpha_0}\left(1+\frac{\alpha_0^2}{k_y^2a^2}\right)\left(\frac{1}{\alpha_0}+i\right),$$

$$\text{if}\quad k_y^2\ll\operatorname{Re}\varkappa^2\ . \tag{16}$$

In order to find the dispersion of the antisymmetric mode we must put $\nu \to \nu + 1/2$ in (16).

When $\varepsilon < 0$, Eqs. (14) and (15) have purely imaginary roots $ka = ik_1$ corresponding to surface waves; the frequency of these is real and for $k_ya \gg 1$ we have

$$\omega^2=\frac{\omega_p^2}{2}\left(1-\frac{1}{4}\frac{\omega_p^2}{c^2k_y^2}\right).$$

We now consider the emission of TM waves from a plasma layer at a finite temperature. It can be shown that the solutions of the system (2) under the given boundary conditions split into two groups. In one group H_z is an even function of x and n is odd (we call these symmetric solutions) and in the other group H_z and n have the opposite parity (antisymmetric solutions). For the symmetric solutions the dispersion equation has the form

$$\frac{ik\operatorname{tg} ka}{\varepsilon}+i\varkappa=k_y^2\left(1-\frac{1}{\varepsilon}\right)\frac{\operatorname{tg} k_1a}{k_1}, \tag{17}$$

and for the antisymmetric solutions

$$\frac{k\operatorname{ctg} ka}{\varepsilon}-i\varkappa=k_y^2\left(1-\frac{1}{\varepsilon}\right)\frac{\operatorname{ctg} k_1a}{k_1}, \tag{18}$$

where $k_\parallel = [(\omega^2/c^2)(\varepsilon/\beta^2) - k_y^2]^{1/2}$ is the projection of the vector of the plasma oscillations along the layer.

When $k_y^2 < \omega^2/c^2$, surface waves are possible and the frequencies of these when $ka \gg (\omega_p a)/c$ are approximately equal to

$$\omega\approx\frac{\omega_p}{\sqrt{2}}\sqrt{1+\frac{k_yv_{Te}\sqrt{2}}{\omega_{pe}}}.$$

In addition, when $\omega \approx \omega_{pe}$, there is a discrete real spectrum of longitudinal plasma oscillations. This spectrum has been derived in ref. 7, for example, in the quasistatic approximation.

We are interested here, however, in the modes emitted from a system for which $k_y^2 < \operatorname{Re}(\omega^2/c^2)$ and $\operatorname{Re}k$, $\operatorname{Re}\varkappa$, $\operatorname{Re}k_\parallel > 0$. Then $\operatorname{Re}\varepsilon > 0$.

Since $|k_\parallel| \gg |k_\perp|$, we can consider two cases: $|ka| \ll 1$, $|k_\parallel a| \sim 1$ and $|ka| \sim 1$, $|k_\parallel a| \gg 1$.

Let us consider the first case.

Equation (17) takes the form

$$i\varkappa=\frac{k_y^2\left(1-\frac{1}{\varepsilon}\right)\operatorname{tg} k_1a}{k_1}, \tag{19}$$

and (18) becomes

$$\frac{1}{\varepsilon}-i\varkappa a=\frac{ak_y^2\left(1-\frac{1}{\varepsilon}\right)\operatorname{ctg} k_1a}{k_1}. \tag{20}$$

Since $|k_y| \ll |k_\parallel|$, we can solve (19) and (20) by the method of successive approximations and thus obtain for the symmetric mode

$$k_1a\approx\left(\nu+\frac{1}{2}\right)\pi-\frac{ik_y^2a^2}{\left(\nu+\frac{1}{2}\right)\pi\varkappa a}\left\{\frac{\frac{\omega_p^2a^2}{c^2}}{\left[\left(\nu+\frac{1}{2}\right)^2\pi^2+k_y^2a^2\right]\beta^2}\right\}, \tag{21}$$

where $\varkappa^2 = (k_\parallel^2 + k_y^2)\beta^2 + (\omega_p^2/c^2) - k_y^2$, $|\varepsilon| \lessdot 1$, $\nu = 0, 1, 2, \ldots$, and for the antisymmetric mode we have

$$k_1a\approx\nu\pi-\frac{k_y^2a^2}{\nu\pi}\left[\frac{\alpha_0^2}{\left(\frac{\nu^2\pi^2}{a^2}+k_y^2\right)a^2\beta^2+\alpha_0^2}\right]$$

$$\times\left(1+i\varkappa a\frac{\left(\frac{\nu^2\pi^2}{a^2}+k_y^2\right)a^2\beta^2}{\left(\frac{\nu^2\pi^2}{a^2}+k_y^2\right)a^2\beta^2+\alpha_0^2}\right),\quad \nu=1,\ 2,\ \ldots. \tag{22}$$

The spectrum of ω values can then easily be found from

$$\omega^2=\omega_p^2+(k_1^2+k_y^2)s^2, \tag{23}$$

and since $k_\parallel$ is complex, ω has a small negative imaginary part, which corresponds to radiation damping of the waves.

In the second case, where $ka \gg 1$, it turns out that $k_{II}r_D \sim 1$ if $a \sim \omega_p/c$ and the resonance terms connnected with the longitudinal oscillations are smeared out as a result of Landau damping, which is not described by the original hydrodynamic equations. Thus when $|ka| \gg 1$, we can neglect the right sides of (17) and (18). The ω spectrum of the emitted modes coincides with that found above for transverse TM waves in the cold plasma approximation. Thus in bounded plasma systems it is possible to have wave damping caused by the emission of fast waves ($v_{ph} > c$). This damping must be taken into account together with that produced by collisions and Landau damping when considering the propagation and nonlinear interaction of waves.

In conclusion we wish to thank V. N. Oraevskii for his interest in this work and for useful discussion.

Stabilization of MHD instabilities by a high-frequency current in a straight system

V. P. Fedyakova

(Submitted March 26, 1973; resubmitted June 12, 1973)
Zh. Tekh. Fiz., 44, 28-33 (January 1974)

We describe an experimental study of the stabilizing action of a hf current which passes through an unstable (Kruskal–Shafranov) plasma with a quasistationary current in a straight system. The amplitude of the hf current needed to stabilize the plasma is smaller than that derived from the theory of dynamic stabilization and the range of stabilization for longitudinal field values is broader. The more effective stabilization is connected with the production of turbulence by the hf current in the plasma skin layer and the creation of a positive gas-kinetic pressure gradient inside the plasma.

The present paper presents the results of an experimental investigation into the possibilities of using a hf current to stabilize MHD instabilities in a plasma in a straight system. The value of the modulation coefficient required to stabilize the Kruskal–Shafranov instability $\eta = I_{\sim m}/I_{-} \simeq 0.3$ ($I_{\sim m}$ and I_{-} are the amplitudes of the hf and quasistationary currents respectively) is smaller than the value $\eta \gg 1$, which has previously been accepted in MHD stabilization theory. The more effective stabilization in the present case can be explained by the presence of a high-temperature cylindrical shell characterized by anomalous conductivity at the surface of the unstable plasma.

1. OBSERVATION OF THE INSTABILITY

The experiment has been carried out on the Omega device described in refs. 1 and 2. A plasma with a quasistationary current I_{-} = 3-10 kA and lifetime of about 280 μsec is created by a discharge between electrodes at a pressure of $p_0 = 10^{-2}$-10^{-3} mm Hg. The discharge takes place in a quartz tube $2a$ = 10 cm in diameter with a distance of L = 90 cm between the electrodes. Measurements with a streak camera and double electric probes show that the plasma is not in contact with the walls, that the density increases towards the axis, and that the boundary of the plasma is limited by the apertures in the end plates (diameter $2a$ = 4 cm). The temperature of the discharge is 10 eV. The experimental evidence all suggests that the plasma has a helical deformation caused by the fact that the Kruskal–Shafranov condition

$$q = \frac{2\pi a}{L}\frac{H_z}{H_\theta} > m \qquad (1)$$

is not satisfied. Here, m is the azimuthal mode number and takes on the integral values 1, 2, 3,... When condition (1) is not satisfied, a perturbation deforms the plasma, which assumes a helical shape with pitch which is greater than or equal to the pitch of the helical field line; all this has been observed in the experiment. The expression for the growth rate of an instability which produces a change in shape of the plasma has been obtained by Leontovich and Shafranov:[3]

$$\gamma^2 = \left|\frac{K_1(k_i a)}{K_0(k_i a)}\right| \frac{1}{4\pi a\rho}\left[-\frac{H_\theta^2 K_0(k_i a)}{a K_1(k_i a)} + k_i H_z^2 \pm \frac{H_\theta H_z}{a}\right], \qquad (2)$$

where K_1 and K_0 are modified Bessel functions, the k_i are the mode wave numbers, and ρ is the plasma density. The nature of the instability is determined experimentally as follows. First, for two values of the current approximate estimates are made of the instability growth rate from oscillograms of the time change in dH_θ at the beginning of the discharge ($t \simeq 0$). For I_{-} = 7 kA, $H_z = 0$, $\gamma \simeq 10^6$ sec^{-1}; for I_{-} = 10 kA and H_z = 1 kOe, $\gamma \simeq 2\cdot10^{-6}$ sec^{-1}. These measured values of γ agree to within ~50% with those calculated from (2). Second, the streak photographs show that the plasma is curved in the axial direction and that the wavelength is equal to the distance between the electrodes. Third, magnetic probes, oriented along azimuth and axis, measure the fluctuations in the magnetic field $\partial H_\theta/dt$ and $\partial H_z/dt$ and their distribution with radius, azimuth, and axial distance. The magnetic field oscillation has two branches: One at a frequency of 200 kHz and another, which modulates the first, at a frequency 30-50 kHz. Simultaneous measurements are made by magnetic probes of the distribution in amplitudes of both modes along the radius of the chamber. The maximum of the 200 kHz mode occurs in the central region; that for the low-frequency mode is near the walls. In the axial direction, the pitch of the helix is equal to the distance between the electrodes. If the position of the endplate limiters is changed, there are changes in the pitch of the oscillations, the frequency, and the spatial amplitude. A comparison of the oscillations of $\partial H_\theta/\partial t$ measured by magnetic probes placed in azimuth around the chamber shows that the plasma rotates at a frequency of 200 kHz. The oscillations in the magnetic field correlate with those in the signal (nT) measured by the double probes near the wall and in the center of the chamber. For 150 μsec the plasma undergoes quasiharmonic oscillations at 200 kHz, periodically touching the walls at a frequency of 30-50 kHz, and the growth rate is given by (2).

The oscillogram of $\partial H_\theta/\partial t$ is used to construct the relationship between the 200-kHz oscillations in the magnetic field and the value of H_z. Figure 1 shows the results for two values of the quasistationary current I_{-} = 4.8 and 8 kA. As the field H_z increases, the amplitude decreases and reaches a minimum for $q = (2\pi a/L)(H_z/H_\theta) > 1$, i.e., when the Kruskal–Shafranov conditions are satisfied. (In practice it is sufficient to suppress the m = 1 mode to eliminate any severe MHD instability.)

It is clear that the helical instability in this experiment with a quasistationary current arises because the Kruskal–Shafranov criterion is not satisfied.

2. SUPPRESSION OF THE INSTABILITY

A quasiharmonic current from a hf generator is used to stabilize the instabilities just described. When the generator is connected across the discharge gap, the overall current $I = I_{-} + I_{\sim}$, where $I_{\sim} = I_{\sim m}\cos\omega t$ is the varying current at a frequency of $\omega = 10^7$ sec^{-1}. Magnetic probes were used to measure the total magnetic field H_θ +

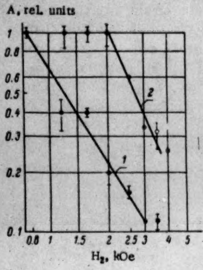

Fig. 1. Variation in the amplitude of the oscillations with the longitudinal magnetic field. 1) $I_- = 4.8$ kA; 2) $I_- = 8$ kA.

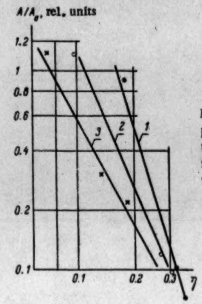

Fig. 3. Variation of the relative amplitude of oscillations in dH_θ/dt with the modul[illegible]on coefficient $\eta = I_{\sim m}/I_-$ for ξ = [illegible] Values of I_- in kA: 1) 3; 2) 5; 3) 7.5.

H_φ, where H_φ is the field of the hf current. The streak photographs and oscillograms of the signal from a photomultiplier directed at a point r = 3.5 cm from the axis of the chamber show that when a hf current $I_{\sim m} = 1$ kA passes through the plasma deformed by a quasistationary current of $I_- = 5$ kA, the plasma becomes linear and the radial oscillations disappear. Measurements by the magnetic probes show that there are no 200-kHz oscillations in the magnetic field of the plasma $\partial H_\theta/dt$.

A series of oscillograms of $\partial H_\theta/\partial t$ shows that the greater the amplitude of the quasiharmonic current, the smaller the oscillation amplitude for a fixed value of $I_- = 5.5$ kA. Similar observations suggest that the suppression of the plasma oscillations is a continuous process. In order to represent the degree of suppression graphically as a function of the discharge parameters, we introduce the following notation. The relative oscillation amplitude A/A_0 is defined as the ratio of the $\partial H_\theta/\partial t$ in a plasma stabilized by the hf current to the amplitude in a plasma with a quasistationary current alone. The modulation coefficient is the ratio of the amplitudes of the hf and quasistationary currents $\eta = I_{\sim m}/I_-$. The ratio of the longitudinal magnetic field to the field of the quasistationary current is denoted by the parameter $\xi = H_z/H_\theta$. The curves $A/A_0 = f(\xi)$, constructed from oscillograms of $\partial H_\theta/\partial t$ (in the time interval 30 μsec < t < 150 μsec) as shown in Fig. 2 indicate that there is a rapid change in the degree of suppression with the longitudinal magnetic field H_z as long as this field is smaller than that produced by the current itself. For $\xi = H_z/H_\theta > 1$-1.5, the relative oscillation amplitude is independent of H_z. The variation of relative oscillation amplitude with the modulation coefficient is shown in Fig. 3 for the case $\xi = 1.5$. As η increases, A/A_0 decreases earlier in a discharge with a higher current; final suppression of the instability (i.e., by a factor of 10 in amplitude) requires a modulation coefficient which is independent of the quasistationary current ($\eta \simeq 0.3$ when $\xi = 1.5$ and is slightly reduced with increase in ξ; η = 0 for ξ = 6). The values of the modulation coefficient required to reduce the amplitude by 10 times are shown in Fig. 4 as a function of ξ for $I_- = 3$, 5, and 7.5 kA. The points indicate the experimental values. The sharp increase in the required value of η for ξ < 1 suggests a change in the suppression mechanism. When $H_z = 0$, it is impossible to get hf stabilization even for the minimum quasistationary current of 3 kA. Stabilization here, if it is at all possible, requires η > 0.8. This might be due to the fact that when $H_z = 0$ the hf current goes to the walls of the chamber and does not create the necessary conditions for stabilization to occur. If only the hf current passes through the discharge channel, then over the whole range of values $0.2 < H_\varphi/H_\theta < 6$, no large-scale instabilities are observed despite the fact that the Kruskal–Shafranov criterion is not satisfied.

When $H_z = 0$, the hf current travels along the chamber walls forming a current cylinder with a skin-layer thickness δ and diameter approximately equal to 2*a* =

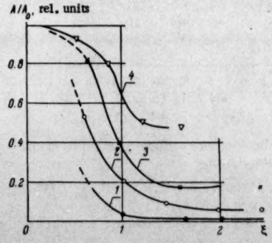

Fig. 2. Variation in the relative amplitude of the oscillations dH_θ/dt of the plasma with $\xi = H_z/H_\theta$ in the presence of a hf current $I_{\sim m} = 1.34$ kA. Values of I_- in kA: 1) 3; 2) 5; 3) 8; 4) 10.

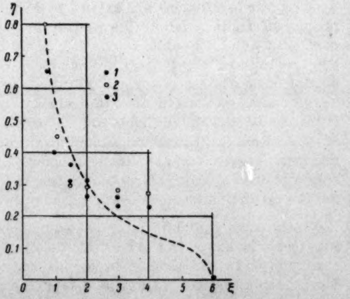

Fig. 4. Variation with $\xi = H_z/H_\theta$ of the modulation coefficient $\eta = I_{\sim m}/I_-$ required to suppress the oscillations in dH_θ/dt by a factor of 10. Values of I_- in kA: 1) 3; 2) 5; 3) 8.

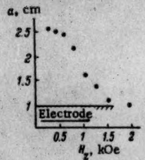

Fig. 5. Variation in the radius of a hf plasma with longitudinal magnetic field. $I_{\sim m}$ = 1.34 kA.

2A − δ. As H_z increases, the diameter of the skin cylinder decreases to that of the electrodes (for $I_{\sim m} = 1.34$ kA according to Fig. 5) when $H_z > H_{z\,cr} = H_\varphi L/2\pi a$. It is possible that in a longitudinal field $H_z < H_{z\,cr}$, the hf discharge is unstable and the widening of the discharge to the walls implies the absence of lf oscillations. When H_z exceeds $H_{z\,cr}$, the hf plasma becomes stable and has the same diameter as the electrodes. We can therefore suggest that the stabilizing action of the hf current on an unstable plasma is more effective when the hf discharge does not touch the walls and has a diameter close to that of the quasistationary plasma.

It is impossible to explain the experimental observations in terms of the dynamic stabilization theory because the values of the modulation coefficient are much smaller and the stability region is much wider than that given by the theories, e.g., refs. 4-7.

The gas-kinetic pressure of the plasma is measured by a diamagnetic probe for deformed and stabilized plasma. The amplitude of the pulse proportional to the pressure is an order of magnitude greater in the second case than in the first (for times $t \leq 30\ \mu$sec, when the cold impurities from the chamber walls have not yet interfered with the measurements). The greatest value of the diamagnetic signal occurs when only the hf current passes through the discharge gap. Spectral diagnostics and measurements with a double electric probe show that the electron temperature in a discharge with a hf current alone ($T_e \simeq 60$ eV) is much higher than with a quasistationary current even when the latter is hf stabilized. The hf field H_φ inside the plasma is concentrated in a skin layer, as in the case in which there is no constant current. It has been shown[8] that when an hf current passes through a skin layer in the discharge gap in the Omega apparatus, ion-acoustic oscillations are excited in the skin layer, the plasma conductivity falls by several orders of magnitude compared with the Coulomb value ($\sigma_{\exp} \simeq 10^{14}$ sec^{-1}, $\sigma_{\mathrm{Coul}} \simeq 10^{16}$ sec^{-1} for $I_{\sim m} = 1$ kA) and there is effective heating of the plasma to $(nT_e) \simeq 2 \cdot 10^{16}$ eV/cm^3 for $n = 2 \cdot 10^{14}$ cm^{-3}. Measurements of the density distribution of the particles with the double probes show that when a hf current passes through a quasistationary discharge, the maximum density occurs in the skin layer. This is probably explained by the preferential heating and ionization of the plasma in this layer.

Since stabilization is accompanied by heating in the skin layer the suggestion arises that the dissipation of electromagnetic wave energy in the skin region might produce a stable system. This idea is related physically to the production of a positive gas-kinetic pressure gradient inside the plasma when a hf current passes through the skin layer. The value of (nT) is a maximum in the current layer and falls to a minimum on the axis; this distribution might be important in the interpretation of the stability. The stabilizing effect of a hollow plasma configuration which does not touch the walls was noted by Tuck[9] back in 1958, when he showed that the stability is connected with the fact that the Suydam conditions

$$\frac{8\pi}{H_z^2}\left(\frac{dp}{dr}\right)+\frac{r}{4}\left(\frac{1}{\mu}\frac{d\mu}{dr}\right)^2>0,\quad \mu=\frac{H_\theta}{rH_z} \tag{3}$$

are satisfied in this case.

In the present experiment the stabilization condition can be estimated approximately as

$$\rho a\gamma^2 < \mathrm{grad}\,(nT). \tag{4}$$

The left side gives the force which deforms the plasma and which has a growth rate (2) (ρ is the plasma density). If grad (nT) inside the plasma is positive, condition (4) is satisfied when

$$\eta > 0.6\xi^{-1}\left|\frac{K_1(k_ia)}{K_0(k_ia)}\right|\left[-\frac{K_0(k_ia)}{K_1(k_ia)}+k_ia\pm\xi\right]. \tag{5}$$

For this to be true, it is necessary that the temperature in the moving plasma should not be able to equalize during the deformation time, i.e.,

$$\gamma > \tau^{-1}. \tag{6}$$

Condition (5) is always satisfied in the present experiment and condition (6), which is indicated graphically in Fig. 5 by the shaded line, coincides with the experimental points in view of the assumptions we have made. Other facts may be enlisted to explain the stabilizing effect of the hf current (for example, the change in the plasma conductivity tensor in the region affected by the hf electric field). However, despite the fact that there is no complete theory of hf stabilization, the experiment shows that the hf current does have a stabilizing effect by producing turbulence in the skin layer.

This work, first, proves the importance of using a hollow-configuration hf current for producing a stable MHD plasma. Secondly, the results have shown that the stabilization of a Kruskal−Shafranov unstable plasma with a quasistationary current requires a hf current with an amplitude some three or more times smaller than that of the quasistationary current, the exact value depending on the longitudinal magnetic field; this assumes that the plasma does not touch the chamber walls and that there is a positive gas-kinetic pressure gradient inside the plasma. Thirdly, the presence of a hf current in a plasma means that it is possible to work with H_z fields smaller than those required by the Kruskal−Shafranov criterion.

In conclusion, the author wishes to thank L. V. Dubovoi for useful discussion.

Nonmonoenergetic relativistic electron beam in a bounded collisional plasma

V. P. Grigor'ev and N. S. Shulaev

Scientific Research Institute of Nuclear Physics, Electronics,
and Automation, Kirov Tomsk Polytechnic Institute
(Submitted April 11, 1973; resubmitted June 26, 1973)
Zh. Tekh. Fiz., 44, 34-37 (January 1974)

The interaction between a low-density relativistic electron beam and a spatially bounded magnetoactive plasma is analyzed. The longitudinal electromagnetic waves excited by the nonmonoenergetic beam are examined allowing for collisions between plasma electrons and heavy particles (neutral molecules or ions); the maximum growth rates are computed as functions of the system parameters. It is shown that an energy spread in the beam electrons results in a stabilization of hydrodynamic instability and the appearance of threshold currents.

A number of papers[1-5] are devoted to the theoretical study of the interaction between a relativistic electron beam and a bounded plasma. Despite the fact that these studies avoid a number of idealizations and bring the statement of the problem close to the experimental conditions, they do not allow for one essential factor: collisions between plasma electrons and heavy particles. As shown in refs. 6 and 7, allowance for collisions and the associated energy dissipation of the electromagnetic waves excited by a monoenergectic beam in an unbounded isotropic plasma results in changes in the interaction picture.

In the present study we investigate the interaction between a bounded nonmonoenergetic beam of relativistic electrons and a dissipative magnetoactive plasma. It is assumed that the uniform beam and plasma completely fill a waveguide of radius R (with ideally conducting walls) and that the system is subject to an external longitudinal magnetic field ($B_0 \parallel z$), with $B_0^2 \gg 8\pi n_b mc^2\gamma_0$, where $\gamma_0 = (1 - v_0^2/c^2)^{-1/2}$, n_b, v_0 are respectively the density and average directed velocity of the electron beam, and n_p is the density of the plasma electrons, $n_p \gg n_b$.

With these assumptions, if we give the perturbations as functions of the coordinates and time in the form $\Phi(r, \varphi, z, t) = \Phi(r)\exp\{i[k_z z + l\varphi - \omega t]\}$, we obtain the following dispersion equation to describe the electrostatic oscillations in the system:

$$1 - \frac{\omega_p^2}{\omega(\omega + i\nu)} - \int \frac{\omega_b^2\gamma^{-3}}{(\omega - k_z v)^2} F_0(\gamma)\, d\gamma + \frac{k_\perp^2}{k_z^2} \times\left[1 - \frac{\omega + i\nu}{\omega}\frac{\omega_p^2}{(\omega + i\nu)^2 - \Omega^2} - \int \frac{\omega_b^2\gamma F_0(\gamma)\, d\gamma}{\gamma^2(\omega - k_z v)^2 - \Omega^2}\right] = 0, \quad (1)$$

where ω_b and ω_p are respectively the plasma frequency of the beam and plasma electrons; $\Omega = eB_0/(mc)$; ν is the effective collision frequency between plasma electrons and heavy particles; $k_\perp = \mu_{s,l}/R$; $\mu_{s,l}$ is the s-th root of a l-th order Bessel function; and $F_0(\gamma)$ is the energy distribution function of the beam electrons in the unperturbed state.

An analysis of (1) indicates that the following waves can be excited in the system: plasma-waveguide waves corresponding to the characteristic spectrum of plasma oscillations in the waveguide,

$$\omega_{1,2}^2 = \frac{1}{2}(\omega_p^2 + \Omega^2) \pm \left[\frac{1}{4}(\omega_p^2 + \Omega^2)^2 - \frac{k_z^2}{k_z^2 + k_\perp^2}\omega_p^2\Omega^2\right]^{1/2}, \quad (2)$$

space-charge waves $\omega \approx k_z v$, and electron-cyclotron waves $\omega \approx k_z v \pm \Omega/\gamma$. The interaction between beam and plasma is strongest in the region of synchronism of the plasma-waveguide waves and the space-charge waves (Cerenkov instability) and the electron-cyclotron waves (cyclotron instability). Below we will consider separately the excitation of Cerenkov and cyclotron instabilities for $\nu/\omega \ll 1$ by an electron beam with an equilibrium distribution of the form

$$F_0(\gamma) = \frac{\Delta\gamma}{\pi}\frac{1}{(\gamma - \gamma_0)^2 + \Delta\gamma^2}, \quad (3)$$

where $\Delta\gamma$ is the longitudinal energy spread and $\xi = \Delta\gamma/\gamma_0 \ll 1$.

1. With synchronism between the plasma-waveguide waves and the space-charge waves the solution of dispersion equation (1) can be written in the form $\omega = k_z v_0 + \delta = \omega_0 + \delta$, $\delta/\omega_0 \ll 1$, where ω_0 is one of the roots of (2). For a dense plasma ($n_b \ll n_p$), limiting ourselves to linear terms in ξ, we obtain the following equation for determining the correction δ from Eqs. (1) and (3):

$$A\frac{\delta}{\omega_0} + \frac{k_\perp^2}{k_z^2}\frac{\omega_b^2\gamma_0}{\Omega^2} + iB - \frac{\omega_b^2}{\gamma_0^3}\frac{(1 + 3i\xi)}{\left(\delta + i\frac{\xi\omega_0}{\gamma_0^2\beta_0^2}\right)^2} = 0, \quad (4)$$

where

$$A = 2\left[\frac{\omega_p^2}{\omega_0^2} + \frac{k_\perp^2}{k_z^2}\frac{\omega_p^2\omega_0^2}{(\omega_0^2 - \Omega^2)^2}\right],$$

$$B = \frac{\nu}{\omega_0}\left[\frac{A}{2} + \frac{k_\perp^2}{k_z^2}\frac{\omega_p^2\Omega^2}{(\omega_0^2 - \Omega^2)^2}\right], \quad \beta_0 = \frac{v_0}{c}.$$

It can be shown from (4) that the maximum growth rate corresponds to the smallest transverse wave number $k_\perp = \mu_{1,0}/R = 2.4/R$ and that electrostatic waves are excited at a frequency $\omega^2 \approx \omega_0^2 \approx \omega_p^2$. Examination of the other branch that results from the solution of (2), $\omega_0^2 \approx \Omega^2$ for $k_z^2 \gg k_\perp^2$, shows that the instability is not excited at this frequency.

We consider the case of a dense plasma and high-energy beams; then

$$2\left(\frac{\nu\gamma_0}{2\omega_p}\right)^{2/3}\frac{\omega_p}{\omega_b} \gg 1, \quad (5)$$

and the solution of (4) corresponding to the unstable branch with maximum growth rate can be written in the form

$$\tilde{\delta} = \frac{\omega_b}{(2\gamma_0^3 B_{\min})^{1/3}}\left[-1 + i\left(1 - \xi\left[\frac{3}{2} + \frac{\omega_p B_{\min}^{1/3}}{\beta_0^2\gamma_0^{1/3}\omega_b}\right]\right)\right], \quad (6)$$

where

$$B_{\min}=\frac{\nu}{\omega_p}\left[1+\frac{\mu_{1,0}^2}{R^2}\frac{\beta_0^2c^2}{\omega_p^2}\right].$$

It follows from (6) that with increasing plasma resistance resulting from collisions between plasma electrons and heavy particles the growth rate for the Cerenkov instability decreases $\sim\nu^{-1/2}$. A low energy spread of the beam electrons also results in a weakening of the interaction between beam and plasma and a reduction in the growth rate.

It can be seen from (6) that for a nonmonoenergetic beam there is a threshold current value below which the Cerenkov instability does not arise:

$$I_{\mathrm{cr}}=\frac{mR^2c}{2e\beta_0^3}\frac{\omega_p^2B_{\min}}{\gamma_0(1-3\xi)}\xi^2. \tag{7}$$

The threshold current increases with the collision frequency $\sim\nu$ and for constant ξ it decreases with increasing beam energy $\sim\gamma_0^{-1}$.

In the opposite case of a less dense plasma in which the inverse of inequality (5) holds, the growth rate for the Cerenkov instability can be written in the form

$$\left.\begin{aligned}\operatorname{Im}\delta&=\left(\frac{\omega_p\omega_b^2}{A_{\min}\gamma_0^3}\right)^{1/3}\frac{(\sqrt{3}-\xi)}{2}-\frac{B_{\min}}{3A_{\min}}\omega_p-\frac{2\omega_p\xi}{3\beta_0^2\gamma_0^2},\\ A_{\min}&=2\left[1+\left(\frac{\mu_{1,0}}{R}\right)^2\frac{\beta_0^2c^2}{\omega_p^2}\right]\end{aligned}\right\} \tag{8}$$

and, as expected, depends only weakly on the collision frequency. Setting $\nu/\omega_p=\xi=0$ in (8), we obtain an expression which coincides with the Cerenkov-instability growth rate in a collisionless plasma.[3]

2. In the region of synchronism between plasma-waveguide waves and electron-cyclotron waves ($\omega\approx k_zv_0\pm\Omega/\gamma_0$), if we represent the solution in the form $\omega=\omega_0+\delta$, ($\delta/\omega_0\ll1$) and allow for the fact that $\omega_b^2/(\gamma_0\Omega^2)\ll1$, we obtain the following equation for the correction $\delta(\delta\ll\Omega/\gamma_0)$:

$$\frac{\delta}{\omega_0}+i\frac{B}{A}\mp\frac{k_\perp^2\omega_b^2}{2k_z^2\Omega\left(\delta+i\xi\frac{\Omega}{\gamma_0}\right)}=0, \tag{9}$$

where the minus sign refers to the fast electron-cyclotron wave and the plus sign to the slow wave.

We can readily show on the basis of (2) and (9) that for a dense plasma ($\omega_p^2\gg\Omega^2$), the instability is excited primarily at large transverse wave numbers $k_\perp$ and frequency $\omega_0\approx\omega_p$. Moreover, the solution of (9) indicates that the slow electron-cyclotron wave has the maximum growth rate:

$$\operatorname{Im}\delta=-\frac{1}{2}\left(\xi\frac{\Omega}{\gamma_0}+\nu\right)+\left[\frac{1}{4}\left(\xi\frac{\Omega}{\gamma_0}+\nu\right)^2+\frac{\omega_b^2\omega_p}{2\Omega}-\xi\frac{\Omega}{\gamma_0}\nu\right]^{1/2}. \tag{10}$$

The threshold current for the instability under consideration can be written in the form

$$I_{\mathrm{cr}}=\frac{mR^2c\beta_0}{2e}\frac{\Omega^2\nu}{\omega_p}\frac{\xi}{\gamma_0}. \tag{11}$$

It can be seen that the threshold current increases in proportion to the spread in energy ξ and the collision frequency ν.

A comparison of the threshold currents for the Cerenkov instability (7) and the cyclotron instability (11) indicates that when

$$\xi\left[1+\left(\frac{2.4}{R}\right)^2\frac{\beta_0^2c^2}{\omega_p^2}\right]\omega_p^2<\beta_0^4\Omega^2 \tag{12}$$

the Cerenkov instability arises. When the opposite of inequality (12) holds, the cyclotron instability is excited.

In conclusion we note that these results are obtained without allowing for collisions between beam electrons and plasma particles; for relativistic beams we will have $\nu_b/\delta\ll\nu/\omega_0$, where ν_b is the collision frequency for beam electrons and plasma particles.

The authors wish to thank A. N. Didenko for his interest.

Second-harmonic generation and emission in wave conversion at a plasma boundary

A. N. Kondratenko, V. G. Shaptala, and V. M. Kuklin
A. M. Gor'kii Khar'kov State University
(Submitted January 8, 1973)
Zh. Tekh. Fiz., 44, 38-42 (January 1974)

The amplitude of the second harmonic emitted from a plasma layer is found for the case in which an electromagnetic wave incident from vacuum excites a longitudinal wave in the plasma. The intensity of the second harmonic at twice the plasma frequency is found as a function of the plasma width, the intensity of the (constant) magnetic field, and the angle of incidence of the wave at the fundamental frequency.

According to the theory of linear conversion of electromagnetic waves at a plasma–vacuum boundary, the field which arises in a plasma when an electromagnetic wave is incident at its boundary increases sharply when longitudinal waves are excited.[1-6] In a plasma layer field amplification is also possible in the case of a spatial resonance. Under these conditions the nonlinear plasma properties can turn out to be important.

In this work we use the approximation of a specified field[7] to analyze the generation and emission of electromagnetic waves at twice the plasma frequency (the second harmonic) by a plane layer of isotropic, magnetized plasma when this plasma is irradiated (from vacuum) by a wave whose electric vector is parallel to the incidence plane (p polarization) and whose frequency is approximately equal to the plasma frequency.

We assume the plasma to be homogeneous with sharp boundaries, and we neglect the changes in the equilibrium density in temperature, caused by the high-frequency field of the incident wave.

Alanakyan[8] has treated the excitation of the second harmonic of an electromagnetic wave in reflection of this wave from the sharp boundary of an isotropic plasma for the case in which the frequency of the incident wave is very different from the plasma frequency.

In the approximation of a slight nonlinearity $[(eE)\cdot(m\omega c)^{-1} \ll 1]$ the excitation of the second harmonic in the plasma is described by the nonlinear wave equation

$$\operatorname{curl}\operatorname{curl}\mathbf{E}_2 + \frac{\varepsilon(2\omega)}{c^2}\frac{\partial^2\mathbf{E}_2}{\partial t^2} = -\frac{4\pi}{c^2}\frac{\partial\mathbf{j}}{\partial t}, \tag{1}$$

where $\mathbf{j}$ is the part of the second-harmonic current which is quadratic in the field of the linear approximation.

Assuming the spatial dispersion to be small (the condition $qv_e \ll \omega$, where v_e is the electron thermal velocity, is always satisfied for propagating waves in a plasma), and assuming the ions to be immobile, we find the following from the equations of the quasihydrodynamic approximation:

$$\left.\begin{gathered}\mathbf{j} = -e\left(n_0\mathbf{v}^{(2)} + \frac{1}{2}n_1\mathbf{v}_1\right),\\ n_1 = -\frac{en_0}{m\omega^2}\nabla\mathbf{E}_1,\quad \mathbf{v}_1 = -\frac{ie}{m\omega}\mathbf{E}_1,\\ \mathbf{v}_2 = -\frac{i}{4\omega}\left\{(\mathbf{v}_1\nabla)\mathbf{v}_1 + \frac{e}{mc}[\mathbf{v}_1\mathbf{H}_1]\right\}.\end{gathered}\right\} \tag{2}$$

The notation is standard.

Using (2), we can convert Eq. (1) to

$$\operatorname{curl}\operatorname{curl}\mathbf{E}_2 + \frac{\varepsilon(2\omega)}{c^2}\frac{\partial^2\mathbf{E}_2}{\partial t^2} = \frac{e\Omega_e^2}{2m\omega^2c^2}\{[\mathbf{E}_1[\nabla\mathbf{E}_1]] + 3\mathbf{E}_1(\nabla\mathbf{E}_1)\}, \tag{3}$$

where Ω_e is the electron plasma frequency.

Equation (3) must be supplemented with boundary conditions for the fields at the plasma–vacuum boundary:[9]

$$\{\mathbf{E}_{2\tau}\} = 0,\quad [\mathbf{n}\{\mathbf{H}_{2\tau}\}] = \frac{4\pi}{c}\mathbf{j}^s, \tag{4}$$

where $\{\mathbf{E}_{2\tau}\}$ and $\{\mathbf{H}_{2\tau}\}$ are the discontinuities in the tangential components of the field at the boundary, $\mathbf{j}^S$ is the surface-current density, and $\mathbf{n}$ is a unit vector normal to the boundary, directed into the plasma.

ISOTROPIC PLASMA

We first consider a plane-parallel layer of isotropic plasma filling the region $0 < z < a$. The incident wave is

$$\left.\begin{gathered}\mathcal{E} = \mathbf{E}_0 e^{i(\mathbf{kr}-\omega t)},\quad \mathcal{E} = (\mathcal{E}_x, 0, \mathcal{E}_y),\\ \mathbf{k} = (k\sin\theta, 0, k\cos\theta),\quad k = \frac{\omega}{c},\quad |\Omega_e^2 - \omega^2| \ll \Omega_e^2,\end{gathered}\right\} \tag{5}$$

where θ is the angle of incidence.

Transverse and longitudinal waves are excited in the layer:

$$\begin{gathered}\mathbf{E}_1 = (\mathbf{L}_+e^{iqz} + \mathbf{L}_-e^{-iqz} + \mathbf{P}_+e^{i\varkappa_1 z} + \mathbf{P}_-e^{-i\varkappa_1 z})\,e^{i(k_x x-\omega t)},\\ q = k\left[\frac{2\varepsilon(\omega)}{3\beta^2} - \sin^2\theta\right]^{1/2},\quad \varkappa_1 = k[\varepsilon(\omega) - \sin^2\theta]^{1/2},\\ \varepsilon(\omega) = 1 - \frac{\Omega_e^2}{\omega^2} + i\frac{\nu}{\omega};\quad \beta = \frac{v_e}{c},\quad \omega > \Omega_e,\end{gathered} \tag{6}$$

where ν is the electron collision frequency.

The amplitudes of the waves are found in the linear approximation from the fields and the vanishing of the normal component of the hydrodynamic electron velocity at the plasma boundary. Using $\varepsilon(\omega) \ll 1$ and $q \gg \varkappa_1$, k, we find

$$\left.\begin{gathered}P_{\pm z} = \pm\frac{E_0qk_x\cos\theta}{\Delta_1\varkappa_1^2}\left[1 \pm e^{\mp i\varkappa_1 a}\left(i\frac{\varkappa_1 q}{k_x^2}\sin qa \mp \cos qa\right)\right],\\ L_{\pm z} = \mp\frac{E_0q^2\cos\theta}{\Delta_1\varkappa_1 k_x}(1 - e^{\mp iqa}),\\ \Delta_1 = -\frac{2q}{\varkappa_1}(1 - \cos qa\cos\varkappa_1 a) - \frac{q^2}{k_x^2}\sin qa\sin\varkappa_1 a.\end{gathered}\right\} \tag{7}$$

Solving Eq. (3), we find the field of the second harmonic in the plasma to be

$$\mathbf{E}_2 = \left(\mathbf{P}_{+2}e^{i\varkappa_2 z} + \mathbf{P}_{-2}e^{-i\varkappa_2 z} + \sum_j \mathbf{B}_j e^{i\xi_j z}\right)e^{2i(k_x x-\omega t)}, \tag{8}$$

where $\mathbf{P}_{\pm 2}$ are the amplitudes of the natural waves, $\varkappa_2 = 2k[\varepsilon(2\omega) - \sin^2\theta]^{1/2}$, and ξ_j and $\mathbf{B}_j$ are the transverse components of the wave vectors and the amplitudes of the induced waves; for brevity we omit the explicit expressions.

The electromagnetic waves at frequency $\omega \sim 2\Omega_e$ which are emitted by the plasma into vacuum propagate parallel to the reflected and transmitted signals at the fundamental frequency:

$$\mathscr{E}_2' = \mathbf{R}_2 e^{2i(\mathbf{k}'\mathbf{r} - \omega t)}, \quad \mathscr{E}_2'' = \mathbf{T}_2 e^{2i(\mathbf{k}\mathbf{r} - \omega t)},$$
$$\mathbf{k}' = (k_x,\ 0,\ -k_z). \tag{9}$$

In our case boundary condition (4) becomes

$$\{E_{2x}\} = 0, \quad \{H_{2y}\} = -i\frac{2\pi e}{c\omega} n_0 v_{1x} v_{1z}|_{z=0} = 0. \tag{10}$$

We thus find the amplitudes of the second harmonic in vacuum to be

$$T_2 = \frac{e^{-2ik_z a}}{\Delta_2}[D(\cos\theta \cos \varkappa_2 a - ig \sin \varkappa_2 a)$$
$$- C(i\cos\theta \sin \varkappa_2 a - g\cos \varkappa_2 a) + gA - B\cos\theta],$$
$$R_2 = \frac{1}{\Delta_2}[B(\cos\theta\cos \varkappa_2 a - ig\sin \varkappa_2 a)$$
$$+ A(i\cos\theta \sin \varkappa_2 a - g\cos \varkappa_2 a) + gC - D\cos\theta],$$
$$C = \frac{ieE_0^2 k_x}{4mk^2\varepsilon(2\omega)c^2}\Big[(P_{+z}e^{i\varkappa_1 a}$$
$$+ P_{-z}e^{-i\varkappa_1 a})(3L_{+z}e^{iqa} - L_{-z}e^{-iqa})$$
$$+ \frac{3}{2}(L_{+z}^2 e^{2iqa} + L_{-z}^2 e^{-2iqa}) + 3L_{+z}L_{-z}\Big],$$
$$D = \frac{-ieE_0^2\varkappa_1\varkappa_2}{4mc^2 k_x k^2\varepsilon(2\omega)}(P_{+z}e^{i\varkappa_1 a} - P_{-z}e^{-i\varkappa_1 a})(L_{+z}e^{iqa} + L_{-z}e^{-iqa}),$$
$$\Delta_2 = i\cos^2\theta \sin \varkappa_2 a - 2g\cos\theta\cos \varkappa_2 a + ig^2 \sin \varkappa_2 a,$$
$$g = \frac{\varkappa_2}{2k\varepsilon(2\omega)}, \quad C|_{a=0} = A, \quad D|_{a=0} = B. \tag{11}$$

Let us analyze these equations for certain particular cases. We assume that to a first approximation the longitudinal wave which is excited propagates in the plasma $[\varepsilon(\omega) > 0]$, while the transverse wave propagates in a "skin," except for angles of incidence in the interval satisfying $0 < \theta < \arcsin[\varepsilon(2\omega)]^{1/2}$.

If the transverse dimensions of the layer are large in comparison with the wavelength of the longitudinal wave and in comparison with the skin depth for the transverse wave, we can use the approximation for a semiinfinite plasma. Here we have $T_2 = 0$ and

$$R_2 = \frac{ieE_0^2 \sin\theta\cos^2\theta[(4\varepsilon(\omega) - \sin^2\theta)^{1/2}(0.75 - \sin^2\theta)^{1/2} - 3\sin^2\theta]}{2mc\Omega_e[\varepsilon(\omega) - \sin^2\theta][(0.75 - \sin^2\theta)^{1/2} + 0.75\cos\theta]}. \tag{12}$$

This equation has two maxima: a sharp maximum at angles of incidence $\theta \approx \arcsin[\varepsilon(\omega)]^{1/2}$ and a weaker maximum at $\theta \approx \arcsin[\varepsilon(2\omega)]^{1/2}$; these maxima are due to total internal reflection of the waves of the first and second harmonics from the plasma boundary.

The relative energy flux carried into vacuum by the second harmonic is

$$W = \frac{|R_2|^2}{E_0^2} = \left(\frac{eE_0}{mc\Omega_e}\right)^2 F(\theta). \tag{13}$$

Figure 1 shows the function $F(\theta)$ for $|\varepsilon| = 0.1$ and $\nu/\omega = 0.01$.

If the plasma layer is much thinner than the skin depth for the transverse wave ($|\varkappa a| \ll 1$), the radiation at frequency $2\Omega_e$ becomes symmetric on the two sides of the layer and becomes about $(\varkappa a)^{-2}$ times more intense than that from a semiinfinite plasma:

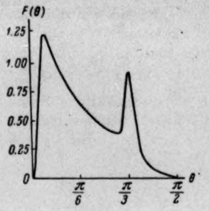

Fig. 1

$$R_2 = T_2 = \frac{8eE_0^2(1 - \cos qa)\cos\theta\sin^3\theta}{3mc\Omega_e(\varkappa a)^2 \sin qa[\varepsilon(\omega) - \sin^2\theta]}. \tag{14}$$

As sin qa decreases the amplitude of the second harmonic in vacuum increases, but at $\sin qa \ll k_x/q$ (corresponding to spatial resonance) Eq. (14) cannot be used; for $qa = (2n + 1)\pi$, where n = 1, 2, 3, . . . , we replace this equation by

$$R_2 = T_2 = \frac{eE_0^2 qa \sin 2\theta}{3m\Omega_e c(\varkappa a)^2}. \tag{15}$$

It follows from Eqs. (12)-(14) that at $\theta = 0$ the radiation at frequency $\omega \sim 2\Omega_e$ vanishes, because in the case of normal incidence a transverse wave at twice the fundamental frequency is not excited in the plasma.

MAGNETIZED PLASMA

We turn now to a plasma layer in a strong, fixed external magnetic field (for which $\omega_e \gg \Omega_e$, where ω_e is the electron gyrofrequency) perpendicular to the plasma boundaries.

In this case a p-polarized wave at frequency $\omega \sim \Omega_e$ incident obliquely excites two quasilongitudinal waves in the plasma:

$$\mathbf{E}_1 = (\mathbf{L}_+ e^{iqz} + \mathbf{L}_- e^{-iqz} + \mathbf{S}_+ e^{i\varkappa_1' z} + \mathbf{S}_- e^{-i\varkappa_1' z}),$$
$$S_{\pm z} = \pm\frac{E_0 q k_x \cos\theta}{\varepsilon^2(\omega)\varkappa_1'^2\Delta_3}\Big[1$$
$$\pm e^{\mp ik_z a}\left(i\frac{\varepsilon(\omega)\varkappa_1' q}{k_x^2}\sin qa \mp \cos qa\right)\Big],$$
$$L_{\pm z} = \mp\frac{E_0 q^2\cos\theta}{\varepsilon(\omega)k_x\varkappa_1'\Delta_3}(1 - e^{\mp iqa}),$$
$$\Delta_3 = -\frac{2q}{\varepsilon(\omega)\varkappa_1'}(1 - \cos qa\cos \varkappa_1' a) - \frac{q^2}{k_x^2}\sin qa \sin \varkappa_1' a,$$
$$\varkappa_1' = k\left[1 - \frac{\sin^2\theta}{\varepsilon(\omega)}\right]^{1/2}. \tag{16}$$

We find the nonlinear wave equation for this case from Eq. (3), taking into account the circumstance that the electrons move in one dimension (along $\mathbf{H}_0$), and taking into account the quasilongitudinal nature of the waves excited in the plasma at frequency $\omega \sim \Omega_e$:

$$\mathrm{curl\ curl}\ \mathbf{E}_2 + \frac{\hat{\varepsilon}(2\omega)}{c^2}\frac{\partial^2\mathbf{E}_2}{\partial t^2} = \frac{3e}{2mc^2}E_{1z}\frac{\partial E_{1z}}{\partial z}\mathbf{h}. \tag{17}$$

Here $\mathbf{h} = \mathbf{H}_0/H_0$, and the nonvanishing components $\varepsilon_{ik}(2\omega)$ are $\varepsilon_{11} = \varepsilon_{22} = 1$, $\varepsilon_{33} = \varepsilon(2\omega)$.

The field of the second harmonic excited in the plasma is

$$\mathbf{E}_2 = \left(\mathbf{S}_{+2}e^{i\varkappa_2' z} + \mathbf{S}_{-2}e^{-i\varkappa_2' z} + \sum_j \mathbf{A}_j e^{i\psi_j z}\right)e^{2i(k_x x - \omega t)}, \tag{18}$$

where $S_{\pm 2}$ are the amplitudes of the natural waves excited in the plasma at the second-harmonic frequency, ψ_j and A_j are the normal components of the wave vectors and the amplitudes of the induced waves, and $\varkappa_2' = \varkappa_1'(2\omega)$.

From the boundary conditions, which are the same as those for an isotropic plasma, (10), we find the amplitudes of the waves emitted by the layer at $\omega \approx 2\Omega_e$ into vacuum:

$$\left.\begin{gathered}
T_2 = \frac{1}{\Delta_4}\left[\frac{\varkappa_2'}{2k} A - C\left(i \sin \varkappa_2' a \cos\theta - \frac{\varkappa_2'}{2k} \cos \varkappa_2' a\right)\right] e^{-2ik_z a},\\
R_2 = \frac{1}{\Delta_4}\left[\frac{\varkappa_2'}{2k} C - A\left(i \sin \varkappa_2' a \cos\theta - \frac{\varkappa_2'}{2k} \cos \varkappa_2' a\right)\right],\\
C = -\frac{iek_x E_0^2}{2m\Omega_e^2}[L_{+z}^2 e^{2iqa} - L_{-z}^2 e^{-2iqa}\\
+ 2(S_{+z} e^{i\varkappa_1' a} + S_{-z} e^{-i\varkappa_1' a})(L_{+z} e^{iqa} + L_{-z} e^{-iqa})],\\
\Delta_4 = i \cos^2\theta \sin \varkappa_2' a - \frac{\varkappa_2'}{k} \cos\theta \cos \varkappa_2' a + i \frac{\varkappa_2'^2}{4k^2} \sin \varkappa_2' a,\\
A = C|_{a=0}.
\end{gathered}\right\} \quad (19)$$

We turn now to certain limiting cases.

For a semiinfinite plasma ($|qa|$, $|\varkappa_1' a|$, $|\varkappa_2' a| \gg 1$), we find from (19)

$$R_2 = \frac{i3e \cos^2\theta \sin^3\theta E_0^2}{m\Omega_e c\varepsilon(\omega)\sqrt{\varepsilon(2\omega)}}\Big\{[\varepsilon(\omega) - \sin^2\theta]\left[\frac{\sqrt{3}}{2}\cos\theta + \left(\frac{3}{4} - \sin^2\theta\right)^{1/2}\right]\Big\}^{-1}. \quad (20)$$

It follows from this equation that the amplitude of the second-harmonic wave emitted into vacuum at a frequency $\omega \approx 2\Omega_e$ is higher for a magnetized plasma than for an isotropic plasma, by a factor of about $1/\varepsilon(\omega) \gg 1$.

The emission of the second harmonic from a thin ($|\varkappa_1' a| \ll 1$) plasma layer is symmetric and more intense than that from a semiinfinite plasma, by a factor of $\sim |\varkappa_1' a|^{-2}$:

$$T_2 = R_2 = \frac{3ie \cos\theta \sin^3\theta E_0^2}{m\Omega_e c\varepsilon(\omega)(\varkappa_1' a)^2[\varepsilon(\omega) - \sin^2\theta]}.$$

Since $\varepsilon(\omega)|\varkappa_1' a|^2 \approx |\varkappa_1 a|^2$, the application of a strong magnetic field to a thin layer of isotropic plasma does not lead to an increase in the waves emitted at $\omega \approx 2\Omega_e$, in contrast with the case of a semiinfinite plasma.

Conversion of an electromagnetic wave into an ion-acoustic wave in an inhomogeneous plasma

A. N. Kondratenko and V. M. Kuklin

A. M. Gor'kii Khar'kov State University

(Submitted February 19, 1973)
Zh. Tekh. Fiz., 44, 43-47 (January 1974)

An electromagnetic wave incident on an inhomogeneous, highly nonisothermal plasma is analyzed. The electric vector of the wave lies in the plane of incidence. The plasma density variation is linear. If the inhomogeneity is pronounced, so that the limiting ion plasma frequency found from the condition $\Omega_i(a) = \omega$ is in the skin layer, an ion-acoustic wave can be excited in the plasma. An equation is derived for the field of the ion-acoustic wave and solved in the asymptotic regions. The ion-acoustic wave is excited near the point $\Omega_i(a) = \omega$, where its amplitude becomes very large; it propagates into the plasma with an amplitude which decays like $\omega \ll \Omega_i(x)$ in inverse proportion to the density. If the skin depth for the electromagnetic wave satisfies $\delta \ll a$, the amplitude of the ion-acoustic wave is exponentially small.

1. The conversion of electromagnetic waves into ion-acoustic waves, and vice versa, at the sharp boundary of a highly nonisothermal plasma is analyzed in ref. 1. However, plasmas have sharp boundaries only in a solid. In a gaseous plasma there is always a transition region, which cannot be narrower than the Debye length. Since the wavelength of an ion-acoustic wave can be comparable to the Debye length, it is clearly of interest to analyze the conversion of low-frequency waves at the boundary of an inhomogeneous plasma.

We consider a semiinfinite, highly nonisothermal plasma ($T_e \gg T_i$) filling the region $x > 0$. Over the interval $0 < x < b$ the plasma is inhomogeneous, and its unperturbed density varies from zero to $n_0(b) \equiv n_0$. For $x \geq b$ the density is constant at n_0. An electromagnetic wave is incident on the plasma at an angle Θ; the electric vector of this wave lies in the plane of incidence, and the frequency of the wave is $\omega < \Omega_i(b)$, where $\Omega_i(b)$ is the limiting ion-plasma frequency. The z axis lies in the plane of incidence of the wave and the incident wave has the components

$$E_x = \alpha H,\ E_z = -\sqrt{1-\alpha^2}\, H,\ H \equiv H_y = e^{i\psi}, \tag{1}$$

where

$$\psi = (\alpha k z + k x\sqrt{1-\alpha^2} - \omega t),\ \alpha = \sin\theta,\ k = \frac{\omega}{c}.$$

In an inhomogeneous plasma the amplitude of the transverse wave decays exponentially[2] away from the point $x = x_0$, determined from the condition $\omega = \Omega_e(x_0) \cdot (\cos\theta)^{-1}$. Accordingly, the wave essentially cannot reach the point of the ion-plasma resonance, at which conditions are suitable for the excitation of an ion-acoustic wave, in a slightly inhomogeneous plasma. We assume the plasma to be highly inhomogeneous, in the sense that the transverse field penetrates a depth $\delta \sim c/\Omega_e(a) \sim a$ into the plasma, where a is found from the condition $\omega = \Omega_i(a)$. If $b \sim a$ the characteristic dimensions of the inhomogeneity are of the order of the skin depth.

Under these conditions we can neglect the singularity of the transverse field and wave conversion at the electron-plasma resonance. Our purpose is to determine the field in the region in which the ion-acoustic wave can propagate.

Writing the functional dependences on the time and z of all plasma properties associated with the waves as $\exp i(k\alpha z - \omega t)$, we find the following system of equations for the field in the plasma from the linearized Maxwell equations and the equations of two-fluid hydrodynamics:

$$\frac{d^2}{dx^2}H + \frac{dH}{dx}\,\frac{\beta_T^2\alpha^2\varepsilon_i \frac{d}{dx}\ln n_0(x) - \frac{d}{dx}\varepsilon}{\varepsilon - \alpha^2\beta_T^2\varepsilon_i} + k^2(\varepsilon - \alpha^2)H = \alpha\beta_T^2\frac{d}{dx}(\varepsilon_i E_x)\,\frac{\varepsilon\frac{d}{dx}\ln n_0 - \frac{d\varepsilon}{dx}}{\varepsilon - \alpha^2\beta_T^2\varepsilon_i}, \tag{2}$$

$$\frac{v_T^2}{\omega^2}\frac{d^2}{dx^2}(\varepsilon_i E_x) + \frac{v_T^2}{\omega^2}\frac{d}{dx}(\varepsilon_i E_x)\,\frac{\alpha^2\beta_T^2\frac{d\varepsilon_i}{dx} - \varepsilon\frac{d}{dx}\ln n_0(x)}{\varepsilon - \beta_T^2\alpha^2\varepsilon_i} + (\varepsilon - \alpha^2\beta_T^2\varepsilon_i)E_x = \alpha(1 - \beta_T^2\varepsilon_i)H + \frac{\alpha\frac{v_T^2}{\omega^2}\frac{d\varepsilon_i}{dx} - \varepsilon_i\frac{d}{dx}\ln n_0(x)}{\varepsilon - \alpha^2\beta_T^2\varepsilon_i}\,\frac{dH}{dx}, \tag{3}$$

$$ikE_z = (\varepsilon - \alpha^2\beta_T^2\varepsilon_i)^{-1}\left[\alpha\beta_T^2\frac{d}{dx}(\varepsilon_i E_x) - \frac{dH}{dx}\right], \tag{4}$$

where $\beta_T = v_T/c$, v_T is the electron thermal velocity, m_e and m_i are the electron and ion masses. We assume the inhomogeneity of the plasma to be linear in the transition layer:

$$\varepsilon_i = 1 - \frac{\Omega_i^2(b)\,x}{\omega(\omega + i\nu)\,b},\quad \varepsilon = \varepsilon_i - \frac{\Omega_e^2(b)\,x}{\omega^2 b},$$

where $\Omega_e(b)$ is the limiting plasma frequency and ν is the effective ion-collision frequency. When the motion of ions can be neglected system (2)-(4) reduces to a system analyzed previously.[2]

The hydrodynamic velocity of the plasma electrons can be determined from

$$\mathbf{v}_e = -\frac{i}{4\pi e\omega n_0(x)}\left\{\varepsilon_i\mathbf{E} - \frac{i}{k}\operatorname{curl}\mathbf{H}\right\}. \tag{5}$$

2. Since system (2)-(4) is complicated we make several simplifying assumptions. We neglect the terms which take account of the effect of the electron thermal motion on the transverse field in the plasma in Eqs. (2) and (4). We also neglect terms proportional to β_T^2 on the right side of Eq. (3) and in the coefficients in this equation. We assume that the dimension of the inhomogeneous region is much larger than the wavelength of the ion-acoustic wave in the plasma. We also neglect the terms proportional to $d/(dx)\ln n_0(x)$. Now system (2)-(4) splits into two equations for the transverse field,

$$\frac{d^2}{dx^2}H - \frac{d}{dx}\ln\varepsilon\,\frac{dH}{dx} + k^2(\varepsilon - \alpha^2)H = 0, \tag{6}$$

$$ikE_z = \frac{1}{\varepsilon}\frac{dH}{dx}, \tag{7}$$

and an equation for the longitudinal field,

$$\frac{d^2}{dx^2}(\varepsilon_i E_x) + \frac{\omega^2}{v_T^2}\varepsilon E_x = \alpha \frac{\omega^2}{v_T^2} H. \tag{8}$$

If we neglect the first term on the left side of Eq. (8), we find the familiar relation between the components of the electromagnetic field in the plasma:

$$E_x = \frac{\alpha}{\varepsilon} H. \tag{9}$$

Taking account of this term increases the degree of the equation, leading to the appearance of a new (ion-acoustic) wave in the region in which it can exist (Re $\varepsilon_i \leq 0$).

Longitudinal electron waves are localized in the region $1 \gg \varepsilon > 0$. Outside this region, on the left or right, the x component of the electric field must have the form of (9). Accordingly, Eq. (9) is a sort of boundary condition on Eq. (8) in the high-frequency region for $|\varepsilon| \gg 1$.

In the present case of longitudinal ion-acoustic waves the situation is slightly different: The ion-acoustic wave appears where Re $\varepsilon_i \leq 0$, so Eq. (9) can be used as a boundary condition only for the region Re $\varepsilon_i > 0$, where the amplitude of the longitudinal wave must fall off quite rapidly away from the point Re $\varepsilon_i = 0$. For negative values of Re ε_i the ion-acoustic wave also appears where a transverse wave cannot exist, because it is exponentially damped. Since there are two independent constants in the solution of Eq. (8), a second boundary condition is required. This condition must give the amplitude of the longitudinal wave in terms of the amplitude of the transverse wave in the region in which both exist (Re $\varepsilon_i \approx 0$). We adopt as this condition the requirement that as the transition region vanishes ($b \to 0$) the solution of Eq. (8) must go over to the solution for a plasma with a sharp boundary, (1). Analytically, this requirement in an inhomogeneous plasma is equivalent to the equation

$$v_{ex}(a) \approx 0, \tag{10}$$

where a is specified by the condition Re $\varepsilon_i(a) = 0$.

In the equation for the ion-acoustic wave, (8), the transverse field appears as a perturbing force which must be found by solving Eqs. (6) and (7) with boundary conditions expressing the continuity of the tangential components of the electromagnetic field at the boundaries. Since $|\varepsilon| \gg \alpha^2$ in the region of interest, and since the dimensions of the region $|\varepsilon| \sim \alpha^2$ are small, we can neglect the quantity α^2 in Eq. (6).

We find the following equations for the longitudinal component of the transverse field: In the region of inhomogeneous plasma[3]

$$E_x^{\mathrm{trI}}(x) = \frac{\alpha}{\varepsilon} H^{\mathrm{I}}(x) = \alpha C \{ I_{1/3}[\gamma u_i^3(x)] - Q I_{-1/3}[\gamma u_i^3(x)] \}, \tag{11}$$

where

$$C = 2\mu \frac{\left(\frac{\gamma}{2}\right)^{2/3} \Gamma\left(\frac{1}{3}\right)}{Q} \left\{ i \left(\frac{\gamma}{2}\right)^{1/3} \frac{\Gamma\left(\frac{1}{3}\right)}{\Gamma\left(\frac{2}{3}\right)} \frac{\mu}{Q} - \sqrt{1-\alpha^2} \right\}^{-1},$$

$$Q = \frac{I_{-1/3}[\gamma u_i^3(b)] + I_{1/3}[\gamma u_i^3(b)]}{I_{1/3}[\gamma u_i^3(b)] + I_{-1/3}[\gamma u_i^3(b)]},$$

$$\gamma = \frac{2}{3}\varkappa\beta_T, \quad \mu = \sqrt{\frac{m_e}{m_i}}, \quad u_i(x) = \frac{\Omega_i(x)}{\omega}, \quad \varkappa = \frac{\omega^3 b}{\Omega_i^3(b)\, v_s},$$

v_s is the sound velocity in the plasma and $\Gamma(x)$ is the gamma function.

In the region of the homogeneous plasma

$$E_x^{\mathrm{trII}}(x) = \frac{\alpha}{\varepsilon(b)} H^{\mathrm{II}}(x) = -\frac{\sqrt{3}}{\pi\gamma u_i^3(b)} \frac{\alpha C e^{-\frac{\Omega_i(b)}{v_s}(x-b)}}{I_{1/3}[\gamma u_i^3(b)] + I_{-1/3}[\gamma u_i^3(b)]}. \tag{12}$$

3. Equation (8) is conveniently written as

$$\frac{d^2}{dp^2}F + \varkappa^2\left(1 + \frac{1}{p}\right)F = \varkappa^2 E_x^{\mathrm{tr}}(p), \tag{13}$$

where $p = -\varepsilon_i$, $F \equiv \varepsilon_i E_x$.

The solution of Eq. (13) in the inhomogeneous region is

$$F^{\mathrm{I}}(p) = A_1 F_1(p) + A_2 F_2(p)$$
$$+ \pi\varkappa^2 \left[-F_1(p) \int_\infty^p E_x^{\mathrm{tr}}(p') F_2(p')\, dp' + F_2(p) \int_\infty^p E_x^{\mathrm{tr}}(p') F_1(p')\, dp' \right], \tag{14}$$

where $F_1(p)$ and $F_2(p)$ are the solutions of the homogeneous equation; these solutions are Whittaker functions of imaginary argument.[4]

For convenience, rather than treating the Whittaker functions we analyze the asymptotic representation[5] of the solution of Eq. (13) for Re $\varepsilon_i < 0$ and in the neighborhood Re $\varepsilon_i \approx 0$:

$$F_1 = \sqrt{p}\, H_1^{(1)}\left(\varkappa \int \left(1 + \frac{1}{p}\right)^{1/2} dp\right),$$
$$F_2 = \sqrt{p}\, H_1^{(2)}\left(\varkappa \int \left(1 + \frac{1}{p}\right)^{1/2} dp\right), \tag{15}$$

where $H_1^{(1,2)}$ are the Hankel functions of the first and second kinds. Here F_2 increases rapidly at Re $\varepsilon_i < 0$ and $|\varkappa \int (1 + 1/p)^{1/2} dp| \gg 1$, i.e., where conditions are not suitable for the ion-acoustic wave and where there must be no increasing solution. We therefore set A_2 equal to zero. As given in (15), $F_1(p)$ satisfies Eq. (13) when the following relations hold:

$$|p| \ll 1 \text{ and } p \gg 1, \quad \varkappa p \gg 1.$$

The case $p \gg 1$, $\varkappa p \ll 1$, corresponding to a plasma with a sharp boundary at large $|\varepsilon_i(b)|$, is of no particular interest.

The solution of Eq. (8) in the region of a homogeneous plasma is

$$F(x) = A_3 e^{iq(x-b)} + \varepsilon_i(b) E_x^{\mathrm{trII}}(x), \tag{16}$$

where $A_3/\varepsilon_i(b)$ is the ion-acoustic amplitude and

$$q = \frac{\Omega_i(b)}{v_s\sqrt{-\varepsilon_i(b)}}.$$

is the wave vector of the ion-acoustic wave.

The last term in Eq. (16), like the term in brackets in Eq. (14), describes the field of the transverse wave.

Using Eq. (10) and the continuity conditions on the field at the x = b boundary, we find the constants to be

$$A_1 = \frac{\alpha C\,\{I_{2/3}(\gamma) - Q I_{-2/3}(\gamma)\}}{\mu^2\sqrt{-\varepsilon_i(a)}\,H_1^{(1)}(2\varkappa\sqrt{-\varepsilon_i(a)})}, \tag{17}$$

$$A_3 = A_1\sqrt{-\varepsilon_i(b)}\,H_1^{(1)}\left(\varkappa\int\left(1+\frac{1}{p}\right)^{1/2}dp\right)\Big|_{p=-\varepsilon_i(b)}. \tag{18}$$

In determining A_3 we have neglected the x component of the transverse wave, because its amplitude is of order of m_e/m_i in comparison with the amplitude of the natural waves (the ion-acoustic waves). In the transition the amplitude of the ion-acoustic wave is

$$E_x^{l\,\mathrm{I}}(x) = \frac{\alpha C\,\{I_{2/3}(\gamma) - Q I_{-2/3}(\gamma)\}}{\mu^2\sqrt{-\varepsilon_i(a)}\,H_1^{(1)}(2\varkappa\sqrt{-\varepsilon_i(a)})}$$

$$\times\ \frac{H_1^{(1)}\left(\varkappa\int\left(1+\frac{1}{p}\right)^{1/2}dp\right)}{\sqrt{p}}\Bigg|_{p=-\varepsilon_i(x)}. \tag{19}$$

For the case b → ∞, i.e., when there is no "plateau" in the function $n_0(x)$, we set Q = 1 in Eq. (19) and write $\varkappa$ as

$$\varkappa = \frac{\omega}{v_s}\left(\frac{dp}{dx}\right)^{-1}.$$

In the region of homogeneous plasma (for finite values of b), we have

$$E_x^{l\,\mathrm{II}}(x) = E_x^{l\,\mathrm{I}}(b)\,e^{iq(x-b)}. \tag{20}$$

Since the amplitude of the electron field in the longitudinal wave, E_x^e, turns out to be approximately m_i/m_e times larger than the amplitude of the longitudinal component of the transverse field, E_x^{tr}, we are confronted with the question of the validity of our simplifications in Eqs. (2) and (4).

We can neglect the longitudinal field in Eqs. (2) and (4) if

$$\left|\frac{dH}{dx}\right| \gg \alpha\beta_T^2\left|\frac{d}{dx}(\varepsilon_i E_x^l)\right|.$$

This inequality reduces to

$$\left|\sqrt{-\varepsilon_i(a)}\right| \gg \alpha^2\beta_T, \tag{21}$$

which holds over a broad range of parameter values.

4. We now turn to certain particular cases.

a) If the frequency of the wave incident on the plasma is approximately equal to the limiting ion-plasma frequency, $\omega \approx \Omega_i(b)$, so that $|\mathrm{Re}\ \varepsilon_i(b)| \ll 1$, the amplitude of the field in the region of homogeneous plasma becomes the same as that in a plasma with a sharp boundary (1), when the transition layer is thin, and we have $(\omega_b/v_s)\sqrt{-\varepsilon_i(b)} \ll 1$:

$$E_x^l(x) = -\frac{2\alpha}{\sqrt{1-\alpha^2} - i\mu}\,\frac{e^{iq(x-b)}}{\varepsilon_i(b)}. \tag{22}$$

In the opposite case of a thick transition layer, with $2\varkappa\sqrt{-\varepsilon_i(b)} \gg 1$ and $b \lessdot c/[\Omega_l(b)]$, we find

$$E_x^l(x) = -\frac{2\alpha}{\sqrt{1-\alpha^2} - i\mu}$$

$$\times\sqrt{\frac{2}{\varkappa\pi}}\,\frac{\exp\left(\frac{i\omega b}{v_s}\sqrt{-\varepsilon_i(b)} - \frac{3\pi i}{4} + iq(x-b)\right)}{\sqrt{-\varepsilon_i(a)}\,H_1^{(1)}(2\varkappa\sqrt{-\varepsilon_i(a)})\,[-\varepsilon_i(b)]^{3/4}}. \tag{23}$$

When $|(\omega_b/v_s)\sqrt{-\varepsilon_i(a)}| \ll 1$ this equation simplifies:

$$E_x^l(x) = \frac{2\alpha}{\sqrt{1-\alpha^2} - i\mu}\sqrt{2\pi\varkappa}\,\frac{\exp\left(\frac{i\omega b}{v_s}\sqrt{-\varepsilon_i(b)} - \frac{3\pi i}{4} + iq(x-b)\right)}{[-\varepsilon_i(b)]^{3/4}}.$$

In the case $b \gg c/[\Omega_e(b)]$ $(\gamma \gg 1)$, the amplitude of the ion-acoustic wave is proportional to $\exp(-3/2\gamma)$, since the transverse wave cannot penetrate into the ion-resonance region.

b) If ω is small in comparison with $\Omega_i(x)$, Eq. (19) represents a traveling wave in the region $|\varepsilon_i(x)| \gg 1$, $|\varkappa\varepsilon_i(x)| \approx \omega x/b \gg 1$; the amplitude of this wave is inversely proportional to the plasma density:

$$E_x^l(x) = \frac{\alpha C\,\{I_{2/3}(\gamma) - Q I_{-2/3}(\gamma)\}}{\mu^2\sqrt{-\varepsilon_i(a)}\,H_1^{(1)}(2\varkappa\sqrt{-\varepsilon_i(a)})}\sqrt{\frac{2}{\varkappa\pi}}\,\frac{\omega^2}{\Omega_i^2(x)}\,e^{i\frac{\omega}{v_s}x - \frac{3\pi i}{4}}.$$

It follows that when the transverse field penetrates into the ion-resonance region we have $b \lessdot c/[\Omega_e(b)]$ and, if $(2\omega_a/v_s)\sqrt{-\varepsilon_i(a)} \ll 1$,

$$|E_x^l(x)| = \left|\frac{2\alpha}{\sqrt{1-\alpha^2} - i\mu}\right|\sqrt{2\pi\varkappa}\,\frac{\omega^2}{\Omega_i^2(x)}. \tag{24}$$

This value differs from the field amplitude in a plasma with a sharp boundary by the factor $\sqrt{2\pi\varkappa}$.

Knowing the amplitude of the ion-acoustic wave, it is also a simple matter to find the transformation coefficient, defined as the ratio of the flux density of the ion-acoustic wave to that of the electromagnetic wave.

Nonlinear plasma waves and ion-acoustic waves in an isotropic plasma

V. Sh. Livadonov and S. M. Fainshtein

Zhdanov Gor'kii Polytechnic Institute

(Submitted February 27, 1973; resubmitted May 28, 1973)
Zh. Tekh. Fiz., 44, 48-52 (January 1974)

Nonlinear longitudinal (plasma and ion-acoustic) waves in an isotropic plasma are investigated. An asymptotic method is used to derive truncated equations for the wave amplitude and phase. Particular solutions allowing for attenuation due to collisions and scattering by random inhomogeneities are analyzed; the nature of the stationary envelopes is clarified. Estimates are given for a plasma in a semiconductor like InSb. The hydrodynamic approximation is used.

Nonlinear waves in media with cubic nonlinearities have been investigated in detail (see, e.g., refs. 1-3). In both isotropic and anisotropic plasmas, self-focusing and self-compression of wave packets resulting from the nonlinear dependence of the permittivity ε_{nl} on the square of the electric field (electrostriction, heating, ionization, etc.) have been considered,[4-6] i.e., the cubic nonlinearity of the initial nonlinear wave equation has, in effect, been taken into account. In this paper we use the example of longitudinal (plasma and ion-acoustic) waves in an isotropic plasma to show that in analyzing interaction effects (and, similarly, self-focusing effects) in an isotropic plasma, it is also necessary to take account of the quadratic nonlinearity; in the second approximation in the small parameter of the problem this yields a contribution to ε_{nl} comparable with the cubic term. An asymptotic method is used to make a systematic analysis of the effects of dispersion, both linear (the term with $d^2\omega/dk^2$, ω and k being the frequency and wave number of the wave) and nonlinear, the nonlinear term being associated with a nonresonant process ($\omega + \omega \rightarrow 2\omega - \omega \rightarrow \omega$, see refs. 1 and 7). We utilize the hydrodynamic equations, i.e., we do not consider kinetic effects like Landau damping; this approach is valid if the velocity of the plasma waves is much greater than the electron thermal velocity and if $T \gg T_i$ for the ion-acoustic waves (T_i and T being the ion and electron temperatures).[8] We derive truncated equations for the complex electric field amplitudes and investigate various particular cases:[1] stationary envelopes and self-compression of the wave packet. We also allow for weak absorption due to particle collisions and scattering by random inhomogeneities in the equilibrium density. Estimates are given for a semiconductor plasma. It is shown that the results can be used for plasma diagnostics and also for obtaining pulsed signals from a longitudinal field.

1. NONLINEAR PLASMA WAVES

Plasma waves in a hot isotropic isothermal[2] plasma are described by the one-dimensional hydrodynamic equations for the electrons[3] and the Poisson equation for the electric field:

$$\frac{\partial E}{\partial x} = 4\pi e\rho,$$

$$\frac{\partial v}{\partial t} - \frac{e}{m}E + \frac{v_T^2}{N_0}\frac{\partial \rho}{\partial x} = -\mu\left(v\frac{\partial v}{\partial x} - \frac{v_T^2}{N_0^2}\rho\frac{\partial \rho}{\partial x}\right) - \mu^2\frac{v_T^2}{N_0^3}\rho^2\frac{\partial \rho}{\partial x},$$

$$\frac{\partial \rho}{\partial t} + N_0\frac{\partial v}{\partial x} = -\mu\frac{\partial(\rho v)}{\partial x}, \tag{1}$$

where E, v, and ρ are the deviations of the electric field, velocity, and density from the corresponding equilibrium values 0, 0, N_0, $v^2_T = \varkappa_0 T/m$ ($\varkappa_0$ is Boltzmann's constant). In the second equation in (1), the term associated with the pressure $v^2_T(\partial\rho/\partial x)/N_0 + \rho$ is expanded in a series including cubic terms. The parameter μ is introduced to denote the fact that the right side is small. We introduce the dimensionless quantities

$$\rho_{dl} = \rho/N_0,\ v_{dl} = \frac{v}{v_T},\ E_{dl} = \frac{eE}{m\omega_0 v_T};\ \left(\omega_0^2 = \frac{4\pi N_0 e^2}{m}\right),\ x_{dl} = x\frac{\omega_0}{v_T},$$
$$t_{dl} = t\omega_0,\ |\rho_{dl}|_{\max} \sim |v_{dl}|_{\max} \sim |E_{dl}|_{\max} \sim \mu \ll 1,\ 1 \gg \frac{kv_T}{\omega_0} \gg \mu.$$

The subscripts dl are omitted below. Using the asymptotic method,[1,7] we obtain a truncated second-approximation equation in μ for the complex amplitude of the electric field of the wave:

$$\frac{\partial a}{\partial t} + \frac{k}{\omega}\frac{\partial a}{\partial x} + \frac{i}{2}\frac{1}{\omega^3}\frac{\partial^2 a}{\partial x^2} = i\alpha a^2 a^*,$$

$$\omega^2 \doteq k^2 + 1\ (k \ll 1),\quad k \equiv k_{dl} = \frac{kv_T}{\omega_0},\ \omega \equiv \omega_{dl} = \frac{\omega}{\omega_0},$$

$$\alpha = -\frac{4}{3}\omega^3 k^2 - \frac{2}{3}\omega k^2 - \frac{1}{6}k^4\omega \simeq -\frac{8}{3}k^2\omega. \tag{2}$$

In deriving (2) we have allowed for both cubic and quadratic nonlinearities in (1); moreover, the right side of (2) incorporates terms with nonlinear dispersion associated with the process $\omega + \omega \rightarrow 2\omega - \omega \rightarrow \omega$.

We consider various particular cases: 1) the first approximation in μ allowing for small wave absorption, this being related either to ordinary collisions [in the second equation of (1) the term $\nu_{\text{eff}}v$] or to scattering of the average field by random inhomogeneities of the density N_0 equal to δN (see refs. 10 and 11). In both cases an additional term is introduced on the right side of (2): $\nu_\delta a$, where $\nu_{dl} = \nu_{\text{eff}}/2\omega_0$ for the case of collisions between electrons and other particles (ν_{eff} being the effective electron collision frequency) and[11] $\nu_\delta \simeq \langle(\delta N/N_0)^2\rangle\, l_0/k$ (where $l_0 = L/r_D$; L is the scale of the inhomogeneity and r_D is the Debye radius) for the case of scattering of the average field $\langle E\rangle$ by random inhomogeneities δN. The solution of (2) to order μ^2 can be readily obtained in the coordinates

$$\xi = t - \frac{x}{v_{gr}};\ A = F(\xi)e^{-\frac{\nu}{v_{gr}}x};\ \delta \equiv \frac{\varphi'_t}{\omega} = \int\frac{\alpha(A^2)'_t}{v_{gr}}dx + \Phi(\xi),$$

where A and φ are the real amplitude and phase of the wave, δ is the frequency deviation, and v_{gr} is the group velocity of the wave. In particular, for cosinusoidal modulation at the boundary x = 0: $A(0, t) = A_0 \cos \Omega t$ and $\delta(0, t) = 0$ the solution is of the form

$$\left.\begin{aligned} A &= A_0 l^{-\frac{\nu}{v_{gr}}x} \cos\left(t - \frac{x}{v_{gr}}\right)\Omega; \quad \nu \equiv \nu_{dl}. \\ \delta &= \delta_0\left[l^{-\frac{2\nu}{v_{gr}}x} - 1\right] \sin 2\Omega\left(t - \frac{x}{v_{gr}}\right), \end{aligned}\right\} \qquad (3)$$

where $\delta_0 = \alpha\Omega A_0^2/(2\nu)$. It is evident from (3) that as x increases the amplitude A decreases exponentially and that the frequency deviation tends to δ_0 as $x \to \infty$. This is readily understood, because as the amplitude decreases (i.e., decreasing nonlinearity), the change in wave phase becomes small and independent of the amplitude. Let us estimate δ_0 for the plasma in an InSb semiconductor: $I = 77°K$, $N \simeq 10^{17}$ cm^{-3}, $\nu_{eff} \simeq 5 \cdot 10^{11}$ sec^{-1}. If we specify a field of $\simeq 200$ V/cm at the boundary $x = 0$, at a distance $L \simeq 0.1$ mm we have $A \simeq 0.5$ mV/cm, and $\delta_0 \simeq 7\%$, where we have assumed that $\Omega/\omega_0 \simeq 0.1$ ($\omega_0 \simeq 10^{14}$ sec^{-1}). Thus, the change in amplitude and frequency deviation can be used to draw conclusions regarding the density of plasma electrons and the collision frequency ν_{eff}.

2) A general analysis of the envelopes, i.e., in which the solution depends on the single coordinate $\eta = t - (x/u)$ (u being the velocity of the envelope), is given in ref. 12. For our case the phase pictures in the (A, A'_η) plane are shown in Figs. 1 and 2, corresponding to solitons or cnoidal waves. Let us consider self-compression of a one-dimensional wave plasma field. Linearizing Eq. (2) for the real amplitudes and phases of the wave near the unperturbed values A_0 and φ_0 and seeking the solution in the form $e^{i\Omega t - iKx}$, we obtain

$$\Omega = Kv_{gr}\left[1 \pm \sqrt{\frac{v_{gr}^2 \varkappa^2 K^2}{4\omega^2} + \alpha\varkappa A_0^2}\right], \qquad (4)$$

where $\varkappa = \beta\omega/v_{gr}^2$ is the dispersion parameter of the plasma wave; $\beta = d^2\omega/(dk^2) \simeq 1/\omega^3$. Since $\alpha\varkappa < 0$, when

$$|\alpha\varkappa A_0^2| > v_{gr}^2 \frac{\varkappa^2 K}{4\omega^2} \qquad (5)$$

the plasma packet is unstable with respect to self-compression.4) We should note that our treatment of self-action in an isothermal plasma is valid if the power absorbed per unit volume

$$Q \simeq \frac{(mN_0 v_\sim^2 \nu_{eff})}{2} \qquad (6)$$

(where $v_\sim$ is the electron velocity in the field of the wave) is sufficiently small, i.e., at a sufficiently large field amplitude A_0 it is necessary to operate in a pulsed mode.

2. NONLINEAR ION-ACOUSTIC WAVES

Consider a strongly nonisothermal plasma ($T \gg T_i$, and for simplicity $T_i \simeq 0$), in which case, in the quasihydrodynamic approximation, the initial system has the form3

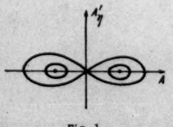

Fig. 1

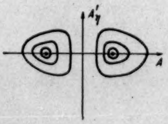

Fig. 2

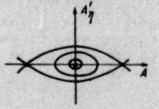

Fig. 3

$$\left.\begin{aligned} &E + \frac{\partial\varphi}{\partial x} = 0, \\ &\frac{\partial E}{\partial x} + \frac{\omega_{0i}^2}{v_{ia}^2}\varphi + \omega_{0i}^2\frac{M}{eN_0}\rho = \omega_{0i}^2\frac{M}{e}\left[\mu\frac{1}{2}\left(\frac{e\varphi}{\varkappa_0 T}\right)^2 - \mu^3\frac{1}{6}\left(\frac{e\varphi}{\varkappa_0 T}\right)^3\right], \\ &\frac{\partial v}{\partial t} + \frac{e}{M}E = -\mu v\frac{\partial v}{\partial x}, \\ &\frac{\partial\rho}{\partial t} + N_0\frac{\partial v}{\partial x} = -\mu\frac{\partial}{\partial x}(\rho v), \end{aligned}\right\} \qquad (7)$$

where E, φ, ρ, v are the deviations of the electric field, potential, density, and ion velocity from the equilibrium values 0, 0, N_0, 0; e/M is the specific charge of the ion; $\omega_{0i}^2 = 4\pi e^2 N_0/M$, $v_{ia} = (\varkappa_0 T/M)^{1/2}$ is the velocity of the ion-acoustic wave, and the parameter μ is introduced to denote the fact that the right sides of (7) are small. In the second equation in (7), we have expanded the function

$$n = N_0 \exp\left(-\frac{e\varphi}{\varkappa_0 T}\right)$$

in a series up to the cubic term (N_0 being the electron density). We introduce the dimensionless variables

$$\rho_{dl} = \frac{\rho}{N_0}, \quad v_{dl} = \frac{v}{v_{ia}}, \quad E_{dl} = \frac{eE}{\omega_{0i} M v_{ia}}, \quad \varphi_{dl} = \frac{e\varphi}{Mv_{ia}^2}, \quad x_{dl} = x\frac{\omega_{0i}}{v_{ia}},$$

$$t_{dl} = t\omega_{0i}; \quad |\rho_{dl}|_{max} \sim |v_{dl}|_{max} \sim |\varphi_{dl}|_{max} \sim |E_{dl}|_{max} \sim \mu \ll 1.$$

Below, the subscript dl is omitted. Using calculations similar to those in Sec. 1, we obtain the truncated equation for the complex potential of the ion-acoustic wave:

$$\left.\begin{aligned} &\frac{\partial a}{\partial t} + \frac{\omega^3}{k^3}\frac{\partial a}{\partial x} - \frac{i}{2}\frac{3\omega^5}{k^4}\frac{\partial^2 a}{\partial x^2} = i\alpha a^2 a^*, \\ &\alpha = -\frac{5}{4}\frac{k^2}{\omega^3} - \frac{3}{4}\frac{k^2}{\omega^5} - \frac{1}{12}\frac{\omega^3}{k^6} + \frac{1}{2\omega k^2} + \frac{1}{4}\frac{\omega^3}{k^4}, \end{aligned}\right\} \qquad (8)$$

where ω and k are related by the dispersion equation5)

$$\omega = \frac{k}{(1 + k^2)^{1/2}}, \quad \omega \equiv \omega_{dl} = \frac{\omega}{\omega_{0i}}, \quad k \equiv k_{dl} = \frac{kv_{ia}}{\omega_{0i}}.$$

Since the parameter $\alpha\varkappa > 0$ ($\varkappa = \beta\omega/v_{gr}^2$, $v_{gr} = \omega^3/k^3$, $\beta = -3\,\omega^5/k^4$) (see Sec. 1), self-compression of a one-dimensional packet of an ion-acoustic wave does not occur. Since $\alpha < 0$ for spatial beams, however, the self-focusing effect should be observed.6 Figure 3 shows phase pictures for a particular class of solutions (stationary waves), i.e., in a nonisothermal plasma it is possible to have shock waves of the envelopes and periodic nonsinusoidal waves. When there is weak absorption (the term νa), the solution is analogous to that given in Sec. 1. Estimates for a laboratory plasma show that it is possible to determine the plasma parameters from the wave absorption and from measurements of the frequency deviation.

The authors are indebted to A. G. Litvak and L. A. Ostrovskii for discussion.

---

[1] The form of the second-approximation equations is the same as in ref. 1, which offers an investigation of general problems without reference to specific systems. In the present paper, therefore, we focus on the specific plasma features of the problems in question.

[2] The conditions under which temperature variations can be neglected are given below.

[3] We consider high-frequency processes, in which the ion motion can be neglected. Moreover, we are not allowing for the force associated with the hf potential, this being valid if $k^2v_T^2/\omega_0^2 \gg m/M$ (where M is the ion mass).[4] In a weak field, we can also disregard resonant scattering by ions.[9]

[4] A similar situation is true of the spatial problem (self-focusing).

[5] We should note that the wave frequency should be ~1, where the dispersion is fairly large and the Landau attenuation for $T \gg T_i$ can be disregarded.

Ionization discontinuity in large-amplitude striations

A. V. Nedospasov and V. G. Petrov

Institute of High Temperatures, Academy of Sciences of the USSR, Moscow

(Submitted May 14, 1973)
Zh. Tekh. Fiz., 44, 53-58 (January 1974)

The potential discontinuity in large-amplitude striations in the positive column in an inert gas is investigated. With energy balance throughout the striation taken into account, a common solution is found for the electron kinetic equation, the continuity equation, and the equation of motion for ions. The potential profile and the electron distribution are found.

INTRODUCTION

Under certain conditions the plasma in the positive column in a discharge becomes unstable, and inhomogeneities arise transverse to the current, caused by an inhomogeneity of the ionization: striations.[1] Near the threshold for their appearance, these striations are of harmonic nature and their amplitude is given by the equations of the quasi-linear theory.[2-5] With a further change in the discharge parameters, leading to a more pronounced instability, the striations become ionization discontinuities: At the head of a striation there is a narrow zone in which a strong electric field separates plasma regions differing by an order of magnitude or more in density.[6] There is a region of gas excitation and ionization associated with this zone. Similar strong-field zones can arise in semiconductors, leading to the generation of microwaves (the Gunn effect).[7]

The hydrodynamic description leads to a satisfactory explanation for low-amplitude waves and the dispersion relations of the striations. However, this description is inapplicable for phenomena in a region in which the plasma parameters change abruptly. In several recent experimental papers a pronounced deformation has been observed in the electron distribution, and groups of fast electrons have been found in this zone.[8-10]

In the present work we find the structure of the discontinuity at the boundary between two striations from a common solution of the kinetic equation for the electron distribution function, the continuity equation, the equation of motion for ions, and the overall balance equations for the energy, ionization, and recombination within a striation. We assume the discharge to be diffusive.

EQUATION FOR THE ELECTRONS

The zone in which the potential is discontinuous in striations is usually quite narrow, and the distribution function changes only slightly as a function of the radius,[10] so we treat the problem in the one-dimensional approximation. The plasma density is small in comparison with the gas density, so that Coulomb scattering of electrons is negligible in comparison with scattering of electrons by atoms. However, the plasma density is high enough so that the plasma is quasineutral (the Debye length is much shorter than the width of the discontinuity).

We consider striations in inert gases in which elastic collisions of electrons with atoms predominate. If the frequency of these collisions is high, and the relative increase in the electron energy over a mean free path is small, the distribution function is approximately spherically symmetric. In this case we neglect the energy loss in elastic collisions in comparison with the energy acquired in the electric field and we neglect energy transfer between electrons.

Under these assumptions the symmetric and antisymmetric parts of the distribution function, f_0 and f_1, satisfy[11]

$$\frac{v}{3}\frac{\partial f_1}{\partial x}+\frac{e}{3mv^2}\frac{d\varphi}{dx}\frac{\partial(v^2 f_1)}{\partial v}=-\frac{f_0}{\tau_D}+St_{1,2}, \tag{1}$$

$$v\frac{\partial f_0}{\partial x}+\frac{e}{m}\frac{d\varphi}{dx}\frac{\partial f_0}{\partial v}+\frac{v}{\lambda_s}f_1=0, \tag{2}$$

where $St_{1,2}$ are the collision terms describing excitation and ionization; these terms are of order $(v/\lambda_c)f_0$, and $(v/\lambda_n)f_0$, respectively. Here, $\lambda_s(v)$, $\lambda_c(v)$, and $\lambda_n(v)$ are the mean free paths of an electron between elastic, excitation, and ionization collisions with gas atoms, and $\tau_D(v)$ is the characteristic time for the diffusive loss of charged particles to the wall. The radial profile of the plasma density, as in a homogeneous column, is given approximately by the Bessel function[12]

$$J_0\left(\mu\frac{r}{R}\right);\ \mu\approx 2.4.$$

We write the equations in the coordinate system moving with the striations toward the cathode. The positive direction of the Ox axis is the direction in which the electrons move.

The ratio f_0/τ_D is given by

$$\frac{f_0}{\tau_D\frac{v}{3}\frac{\partial f_1}{\partial x}}\sim\frac{f_0}{\tau_D\frac{\lambda_s v}{3}\frac{f_0}{s^2}}\sim\frac{D_a\mu^2 S^2}{D_e R^2}\ll 1,$$

where D_e and D_a are the coefficients for ambipolar diffusion and for electron diffusion, R is the radius of the discharge tube, and S is the characteristic dimension for changes in the distribution function; S is equal in order of magnitude to the width of the discontinuous region.

In the striation in front of the potential drop the loss of charged particles to the wall is much more rapid than ionization, but to the right of the potential drop, toward the anode, the rate of inelastic collisions increases. Kinetic equations (1) and (2) are analyzed in that part of the discontinuity in which excitation and ionization can still be neglected.

Nastoyashchii[13] solved system (1), (2) with vanishing right sides.

The boundary conditions for system (1), (2) on the cathode side of the discontinuous zone can be determined from the experimental data. The electric field is known to be weak over most of the striation, and the electron energy is approximately constant. We take the reference point to be the point at which the electron energy begins to increase.

The symmetric part of the distribution function is assumed to be Maxwellian; the non-Maxwellian part at electron energies higher than the first excitation level, where there are relatively few electrons, has no significant effect on the electron density or the potential profile. The asymmetric part of the distribution function on the cathode side of the discontinuous zone is found from (2).

We write the boundary conditions as $\varphi = 0$, and $d\varphi/dx = d\varphi/dx|_0$:

$$f_0 = A\exp\left\{-\frac{mv^2}{2T}\right\},\quad f_1 = \frac{\lambda_s}{l}A\exp\left\{-\frac{mv^2}{2T}\right\}$$

at x = 0. Here

$$A = \frac{n_1}{\left(\frac{2T\pi}{m}\right)^{3/2}},\quad \frac{1}{l} = \frac{e\left.\frac{d\varphi}{dx}\right|_0}{T} - \frac{1}{n_1}\left.\frac{dn}{dx}\right|_0,\quad n_1 = n(0)$$

(the quantity λ_s/l represents the directionality of the electron motion at x = 0).

The solution of Eqs. (1) and (2) under these boundary conditions is, for $\varepsilon = (mv^2)/2 - e\varphi > 0$,

$$f_0 = A\left[1 - \frac{\varepsilon\lambda_s(\varepsilon)}{l}\int\limits_0^x \frac{dx}{(\varepsilon + e\varphi)\lambda_s(\varepsilon + e\varphi)}\right]\exp\left\{-\frac{\varepsilon}{T}\right\}, \tag{3}$$

$$f_1 = A\frac{\varepsilon\lambda_s(\varepsilon)}{(\varepsilon + e\varphi)l}\exp\left\{-\frac{\varepsilon}{T}\right\}. \tag{4}$$

and the solution for $\varepsilon < 0$ is $f_0 = f_1 = 0$. (Here ε in the integrand is assumed an independent variable.)

The mean energy of the primary electrons moving away from the cathode increases; an estimate of the stepwise-ionization time τ_n yields the inequality $V_{st}\tau_n > l$ (V_{st} is the striation velocity). The ionization thus occurs primarily beyond the potential drop. Ionization events maintain a high density of slow secondary electrons on the anode side of this drop. These electrons from the cathode side are retarded by the potential drop and the density of these electrons can be determined from the Boltzmann equation

$$n = n_2\exp\left\{-\frac{e(\varphi_2 - \varphi)}{T}\right\}, \tag{5}$$

where n_2 and φ_2 are the maximum electron density and the potential drop.

Integrating Eq. (3) over v we can find the fast-electron density as a function of the electric potential: $n_f = 4\pi\int\limits_0^\infty v^2 f_0 dv$. The total electron density in the discontinuous zone is given [in terms of the dimensionless variables $z = x/l$ and $u(z) = (e\varphi)/T$] by

$$n = \frac{2n_1}{\sqrt{\pi}}\int\limits_0^\infty\left[1 - \frac{\varepsilon}{T}\lambda_s\left(\frac{\varepsilon}{T}\right)\int\limits_0^z \frac{dz}{\left(\frac{\varepsilon}{T} + u\right)\lambda_s\left(\frac{\varepsilon}{T} + u\right)}\right]$$
$$\times\sqrt{\frac{\varepsilon}{T} + u}\exp\left\{-\frac{\varepsilon}{T}\right\}d\frac{\varepsilon}{T} + n_2\exp\left\{-\frac{e\varphi_2}{T} + u\right\}. \tag{6}$$

IONIZATION–RECOMBINATION BALANCE WITHIN A STRIATION. EQUATION FOR THE IONS

The relation between the potential drop and the maximum electron density can be determined approximately from the known experimental data and from the assumption that the potential drop incorporates essentially the entire voltage difference over a striation.

Assuming that all the ions produced in a striation recombine at the wall within the given striation, we find the following equation from the energy-balance equation:

$$i\varphi_2 = K2\pi R\int\limits_0^{l_{st}}\left.\frac{\partial n}{\partial r}\right|_R dx \approx \mu\pi K D_a\int\limits_0^{l_{st}} n_0 dx \approx \mu\pi K D_a\frac{n_2}{2}l_{st}\,. \tag{7}$$

Here, K is the ionization expenditure, i.e., the average energy expended on the production of a single electron–ion pair; l_{st} is the length of the striation; and $i = (8\pi^2)\cdot e/3\int\limits_0^R r\left(\int\limits_0^\infty v^3 f_1 dv\right)dr$ is the total current.

The ionization expenditures can be found from experimental data on the positive column by comparing the average power evolved per unit length of the column with the current density of ions to the wall. The ionization expenditure is usually a few times the binding energy of the electron in the given atom.

The system of equations for the potential is closed by adding an equation for the ions; this is found by substituting the directed ion velocity $v_i = -b_i(d\varphi)/(dx) + V_{st}$ (where b_i is the ion mobility) into the continuity equation. Using the dimensionless variables z and u(z), we can write this equation as

$$\frac{d^2u}{dz^2} = -\frac{1}{n}\frac{dn}{dz}\left(\frac{du}{dz} - \frac{V_{st}l}{b_i T}\right) + \frac{D_a e}{b_i T}\frac{\mu^2 l^2}{R^2}. \tag{8}$$

SOLUTION FOR ARGON

System (6)–(8) simplifies considerably for argon, for which the mean free path satisfies[14] $\lambda_s \sim 1/v^2$ over the energy range 0.5–13 eV.

Here, Eq. (3) becomes

$$f_0 = A(1 - z)\exp\left\{-\frac{\varepsilon}{T}\right\};\quad \varepsilon > 0. \tag{9}$$

The dispersion in the distribution function does not change with increasing potential, so we can write

$$D_a = \frac{b_i}{e}\frac{\int\lambda_s v^3 f_0 dv}{\int\lambda_s v^2\frac{\partial f_0}{\partial v}dv} = \frac{b_i}{e}T.$$

We can write (6) and (8) as a single, relatively simple equation for the potential:

$$\frac{d^2u}{dz^2}=\left(\frac{du}{dz}-\frac{V_{st}\,l}{D_a}\right)$$

$$\times\frac{-\sqrt{u}+\left[(1-z)\frac{du}{dz}-1\right]I(z)+\frac{n_2}{n_1}\frac{2}{\sqrt{\pi}}\frac{du}{dz}\exp\left\{-\frac{e\varphi_2}{T}+u\right\}}{(1-z)\left[\sqrt{u}+I(z)\right]+\frac{n_2}{n_1}\frac{2}{\sqrt{\pi}}\exp\left\{-\frac{e\varphi_2}{T}+u\right\}}+\frac{\mu^2l^2}{R^2}, \quad (10)$$

where

$$I(z)=\int_0^\infty\frac{e^{-y}dy}{\sqrt{y+u(z)}}.$$

This solution is described by a monotonically increasing curve with an inflection point near the point at which the density of fast electrons, arriving from the left, becomes comparable to the density of slow electrons, arriving from the right. The electric field (du/dz) becomes so strong that the last term in (10) becomes inconsequential on the right of this point, especially since it is partially offset by ionization. The solution consists of two parts: In the left-hand region, where the charged-particle density is essentially the same as the primary-electron density, the electric field increases. Here we can neglect the terms in (1) corresponding to excitation and ionization.

In the right-hand region, where the slow-electron density is predominant, the electric field is weaker; here the solution is meaningful as long as this field is strong enough that we can neglect the ionization term in the potential equation. As we mentioned above, the ionization of excited atoms is shifted to the right from the point at which these excited atoms are produced, by a distance of about l.

To determine the average electron energy in the region in which the electric field decays, we must analyze the vanishing of fast electrons in inelastic collisions. It is difficult to solve the kinetic equation simultaneously taking into account the inhomogeneity of the electric field and inelastic collisions. However, we can estimate a characteristic length for the decay of the fast-electron density under the assumption that there is no electric field.

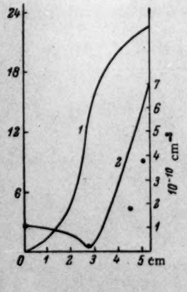

Fig. 1. Potential (1) and electron density (2) as functions of x. The points are the experimental values[10] of n_e.

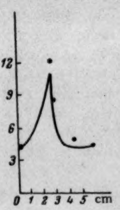

Fig. 2. Average electron energy as a function of x. The points are experimental.[10]

In this case we find the following equation for primary electrons from Eqs. (1) and (2):

$$\lambda_s\frac{\partial^2 f_0}{\partial x^2}=\frac{3}{\lambda_H}f_0;\quad\frac{1}{\lambda_H}=\frac{1}{\lambda_c}+\frac{1}{\lambda_n}.$$

Its solution can be written as follows, with the boundary condition $f_0 = f(v)$ at $x = x_0$:

$$f_0=f(v)\exp\left\{-(x-x_0)\sqrt{\frac{3}{\lambda_s\lambda_H}}\right\}.$$

We can approximate the boundary function by solution (9) at the field maximum.

COMPARISON WITH EXPERIMENT

We compare our results with the experimental data of ref. 10, found from measurements of the distribution function in large-amplitude striations in inert gases.

We select the case of argon at a pressure of 0.25 torr; the radius of the discharge tube is 3 cm, and the current is 0.4 A. Under these conditions the measured thickness of the discontinuous zone is 3 cm, and all the approximations used above are satisfied. With the measured electron density of $\sim 10^{10}$ cm^{-3} ahead of the potential drop, and with the measured electron temperature of 2.4 eV, the mean free path for elastic collisions is ~ 0.1 cm; the energy-relaxation lengths of electrons for collisions between electrons and for collisions between electrons and neutrals are higher than 10 cm.

The ionization expenditure is found from the data of ref. 15, where simultaneous measurements are made of the electron density, the electron temperature, and the average electric field in a tube 1 cm in radius with a current of 0.3 A.

At an argon pressure of 0.75 torr and at the value of the product pR given in ref. 10 (0.75 cm · torr) the ionization expenditure is 170 eV, i.e., approximately 11 times the ionization energy. The striation length, which appears in Eq. (7), can be set equal to four times the tube diameter; this is a valid assumption for the initial conditions in a large number of experiments on striations in argon. The

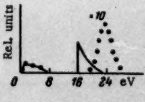

Fig. 3. Comparison of experimental (points) and calculated (solid curve) electron distribution functions.

potential profile calculated from Eqs. (10) and (7) is shown in Fig. 1. The distributions of the density and of the average electron energy are compared with the experimental points in Figs. 1 and 2. Figure 3 shows the calculated and experimental distribution functions near the maximum average energy. The electron densities on the two sides of the potential drop differ by a factor of 25, according to the measurements of ref. 10; our calculations yield $n_2/n_1 \approx 60$.

The agreement with the experimental density drop is satisfactory, especially since the measurements of the electron density in ref. 10 are not very accurate.

In the case of a strong electric field the shape of the electron distribution is a strong function of the longitudinal coordinate. Under these conditions we find a satisfactory agreement between the measured and the calculated distribution functions.

In conclusion the authors thank A. F. Nastoyashchii for useful comments and Yu. L. Igitkhanov and V. D. Khait for discussion.

Experimental investigation of anode processes in a closed electron-drift accelerator

I. V. Melikov

(Submitted March 7, 1973)
Zh. Tekh. Fiz., 44, 59-64 (January 1974)

The discharge regions adjacent to the anode surface in a closed electron-drift plasma accelerator (ACED) are studied. Electrons from the accelerator channel pass through the anode apertures entering into the internal cavity; these electrons cause primary ionization of the working gas (xenon) fed through the anode. Probe methods are used to determine the plasma parameters near the apertures in the anode (T_e = 5-13 eV and $N_e \approx 10^{10}$-10^{11} cm^{-3}) and the dependence of the parameters on the accelerator voltage and gas flowrate. The neutral gas pressure in the anode cavity is measured (~1 mm Hg) as a function of gas flowrate and mode of operation.

INTRODUCTION

References 1 and 2 report on experimental investigations of one-lens plasma accelerators with closed electron drift and an extended acceleration zone. The basic emphasis in these studies is on general characteristics of the accelerator, measurement of the physical plasma parameters in the channel, and the effect of the magnetic field configurations on the operation. When there is an extended ionization zone resulting in a broadening of the ion energy spectrum at the accelerator output,[1] it is also of interest to investigate both the ionization zone itself in the channel and the processes that occur in direct proximity to it, namely inside the anode through which the working substance is fed to the accelerator channel. The state of the working gas at the anode defines the initial conditions for subsequent development of ionization and acceleration processes in the channel. The present paper presents results of an experimental investigation of anode processes.

EXPERIMENTAL ARRANGEMENT AND PROCEDURE

Figure 1a shows a diagram of the accelerator model. Unlike the models used in refs. 1 and 2, the magnetic system has one magnetization coil. Moreover, the external insulator of the coaxial channel is provided by a tube of transparent quartz glass and windows are cut into the housing of the magnetic circuit. This makes it possible to observe and photograph the discharge both in the neighborhood of the anode and in part of the accelerator channel. The inner channel wall is also made of quartz.

Two types of anode are investigated: a "plane" anode and a "box-shaped" anode. The former is a stainless-steel plate 1.5 mm thick with 20 holes 2 mm in diameter for the gas to escape (holes of this size are chosen from considerations of optimum visual observation of the discharge in the regions adjacent to the anode). The working gas is fed into the cavity formed by the anode and an end-on insulator blocking the channel. Two tubes that support the anode and provide the current feed are also used for the leads of the probe circuits, these being mounted in the region beyond the anode over holes on the side that the gas is fed from, 3 mm from the anode surface. The probes are single cylindrical probes (tungsten wire 0.35 mm in diameter and 8 mm long); plane probes (tantalum, 4 × 4 mm) are also used.

The second type of anode is a hollow toroidal box similar to that used in refs. 1 and 2, with holes 0.5 mm in diameter for the gas to escape into the channel. The lateral surface of the anode has a quartz-glass window, and a single plane probe is mounted inside the anode over one of the gas-feed holes. In a number of experiments one of the anode tubes is used to measure gas pressure in the anode cavity (relative to the pressure in a vacuum chamber) using a U-tube manometer filled with PÉS-1 polyethylsiloxane fluid (specific gravity 0.87 g/cm^3).

NATURE OF DISCHARGE IN REGIONS ADJACENT TO THE ANODE

The use of transparent quartz as an insulation material for the outer channel wall, and the design features of the anodes make it possible to observe and photograph the discharge in both the anode region on the side of the accelerator channel and within the anode. Figure 2a shows a photograph of the discharge with one plane-anode version. In the photograph the anode is horizontal and the plasma flow is from top to bottom. The central core of the magnetic circuit can be seen through the transparent inner wall of the channel.

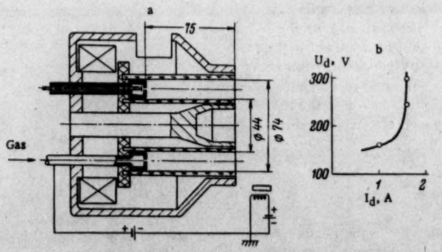

Fig. 1. a) Diagram of the accelerator model; b) volt–ampere characteristic of the discharge (xenon, $\dot{m}$ = 1.3 mg/sec).

Fig. 2. Nature of discharge in accelerator with "plane" (a) and "box-shaped" (b) anodes.

Analysis of the resultant patterns shows that the discharge in the region adjacent to the anode is localized in the vicinity of the holes, with bright plasma "flares" propagating in the channel parallel to the axis over a distance on the order of 2-5 mm (depending on the mode of operation) for a characteristic hole diameter of 2 mm. It is also evident that similar plasma emission in the region of the holes is observed inside the anode cavity on the side from which the gas is fed. The plasma "flares" are a bright blue-white and are clearly distinguished against the general reddish background of the plasma in the anode zone. (The color spectrum of the discharge is reproduced well when color slides are taken.)

With the box-shaped anode the discharge is similar (Fig. 2b). The photograph reveals plasma flares that flow into the accelerator channel through the holes. In this anode the holes are much smaller in diameter (0.5 mm as opposed to 2 mm), so that the plasma emission in the neighborhood of the holes is less pronounced than in the former case; nonetheless it can be seen fairly clearly through the window in the lateral surface of the anode. (The effect is less pronounced in the photographs because of the great difference in plasma emission intensity inside the anode and in the accelerator channel.)

On the basis of visual observation of the discharge in the anode regions we can assume that high-energy electrons penetrate from the channel into the anode through the holes, and electron-impact ionization of the working substance begins in the cavity of the anode itself and in the holes, i.e., to some degree we have a "hollow-anode" effect. The enhanced ionization probability also stems from the higher density of neutrals in these regions as compared to the initial segment of the accelerator channel. Thus, the gas that enters the zone of influence of the accelerating electric field from the anode is partially ionized.

MEASUREMENTS INSIDE THE ANODE

We use probe measurements and measurements of the gas pressure in the cavity of the box-shaped anode to obtain estimates of the plasma parameters inside the anode. The volt–ampere characteristics of both the plane and cylindrical probes have the customary form with pronounced ion-current saturation. By processing the ion branch and the initial segment of the electron branch of the characteristics,[3,4] we are able to evaluate the temperature of the electrons that penetrate into the anode cavity,

$$\frac{kT_e}{e}=\frac{1}{\dfrac{d\ln(I_\Sigma-I_{i0})}{dU}},$$

and also the charged-particle density in the region of the holes inside the anode at a distance of 3 mm from its inner surface:

$$I_{i0}=\frac{I_\Sigma}{2}en_eS\sqrt{\frac{kT_e}{M}},$$

where I_Σ is the total current on the probe, I_{i0} is the saturation ion current at the floating potential, S is the working area of the probe, M is the ion mass, e is the charge of the electron, T_e is the electron temperature, and n_e is the electron density. Plasma neutrality, $n_e \simeq n_i$ is assumed to hold.

Figure 3a shows T_e and n_e as functions of the voltage U_p for a plane anode, while Fig. 3b shows the same for a box-shaped anode with a xenon flowrate of 1.3 mg/sec. The experimental points on the curves correspond to typical modes of operation of the accelerator as noted on the volt–ampere characteristic (Fig. 1b). As U_p increases the electron temperature has a pronounced tendency to increase from 5-7 eV when the accelerator operates on the shallow segment of the characteristic (incomplete-ionization mode) to 10-13 eV at elevated discharge voltages (in a mode close to that of complete ionization). In the latter case, the dependence of T_e on U_p becomes saturated with further increases in U_p.

The charged-particle density in the anode cavity in the vicinity of the holes also increases with U_p, the characteristic density value being $n_e \simeq 10^{11}$ cm^{-3} for a plane and $n_e \simeq 10^{10}$ cm^{-3} for a box-shaped anode. This difference in n_e can be explained by the smaller hole diameter in the latter case. Figure 3c shows T_e and n_e inside the box-shaped anode as functions of the gas flowrate through the accelerator at U_p = 240 V. In the range 0.8-2.5 mg/sec an increase in the neutral gas flowrate leads to some electron cooling and to a stronger change in density in the region of the holes inside the anode.

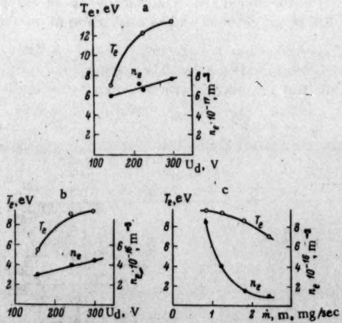

Fig. 3. Variation in electron temperature T_e and density n_e in the vicinity of the holes inside the anode: a) plane anode, xenon, $\dot{m}$ = 1.3 mg/sec; b) box-shaped anode, xenon, $\dot{m}$ = 1.3 mg/sec; c) box-shaped anode, U_d = 240 V.

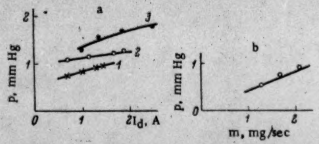

Fig. 4. Variation in gas pressure inside the cavity of box-shaped anode: a) during operation of accelerator; b) with cold gas blow-through; ṁ values, mg/sec: 1) 1.3 (xenon); 2) 1.7; 3) 2.

In view of the observed electron penetration from the accelerator channel through the holes in the anode into the inner cavity it is of interest to evaluate the gas pressure in the anode at which ionization occurs.

Figure 4 shows the change in gas pressure as measured by a U-tube manometer in a box-shaped anode for several xenon flowrates as a function of the discharge current at various points of the accelerator volt—ampere characteristic; the figure also shows the neutral gas pressure as a function of flowrate for cold flow-through of the anode (in the absence of a discharge). Despite the relatively low accuracy of this method of measurement, it is entirely possible to determine the gas-pressure level in the anode in question (1-1.5 mm Hg) and to investigate the way in which it depends on the accelerator's mode of operation.

Thermocouple measurements of the temperature of the front surface of the anode show that in the stationary mode customary for these tests ($\dot{m}$ = 1.3 mg/sec, I_d = 1.6 A) the anode temperature is T_a = 450°C and that it remains virtually constant with increasing voltage once the discharge-current saturation mode has been reached. Assuming that the gas temperature can rise to values of the order of T_a over the dwell time of the gas in the anode cavity (the mean free path at the above pressures being 0.1 mm), we can estimate the neutral-particle density in the anode; it turns out to be $\sim 10^{16}$ cm^{-3}.

DISCUSSION

Our experimental investigation of intraanode processes in an ACED has shown that penetration of high-energy electrons from the accelerator channel into the anode cavity causes initial ionization of the working gas inside the anode and the holes prior to the arrival of the gas in the accelerator zone.

The resultant estimates for the electron temperature inside the anode in the vicinity of the holes for various accelerator modes, T_e = 5-13 eV, coincide with the characteristic value T_e = 10 eV in the accelerator channel.[1] It has been noted, moreover, that the electron temperature increases within these limits with increasing discharge voltage in going from the mode in which the accelerator operates on the shallow section of the volt—ampere characteristic to a mode which is close to one of complete ionization. Further increases in U_d result in saturation of the dependence of T_e on U_d. Since the electrons that penetrate into the anode and the electrons near the side of the accelerator channel are obviously at the same temperature, the measured values of T_e to some extent characterize the level of this parameter in the channel. It is probable that in the accelerator channel the behavior of the electron temperature as a function of discharge voltage is similar to that given above.

The charged-particle density inside the anode at 3 mm from its surface (as evaluated by probe measurements) is 10^{10}–10^{11} cm^{-3}, depending on the hole diameter, which, for a characteristic pressure in the anode cavity of 1 mm Hg, corresponds to a relatively insignificant degree of plasma ionization, 10^{-6}–10^{-5}. Because the measurements are performed at the boundary of the region of virtual plasma emission inside the anode, and because the probability of ionization in the holes themselves is fairly large, we expect that the degree of ionization of the working gas entering the channel will be substantially greater than these values.

The authors wishes to thank A. I. Morozov for proposing the topic and V. V. Fishgoit for valuable comments.

(Submitted January 20, 1973)
Zh. Tekh. Fiz., 44, 65-72 (January 1974)

An experimental study has been made of the dynamics and radiation of high-current pulsed discharges (at currents up to ~300 kA) with return currents up to 100 cm long. These return currents are produced by the electrical explosion of many wires arranged along the generatrices of a cylinder in air. A study has been made of the dynamics of contracting, expanding, and steady-state plasma shells. In none of the experiments do individual discharge channels formed by the explosion of each wire coalesce into a single current shell. The characteristic dimensions and temperatures and the radiation emitted in various spectral ranges have been determined. Such discharges convert electrical energy into radiation efficiently.

1. INTRODUCTION

We have previously[1] pointed out the possibility that cylindrical plasma shells could be produced by the simultaneous explosion of many wires in air at atmospheric pressure, and we have described the basic characteristic of such shells for system of the Triax type,[2,3] i.e., for systems in which the shell has a certain steady-state radius corresponding to the magnetic field profile inside and outside the shell. This profile is achieved[3] when a current I_0, equal to half the discharge current $2I_0 = I_d$, flows inside the shell. The study of such discharges is of much practical as well as purely scientific interest: These discharges seem to be more promising than linear pinches for producing high-intensity radiation sources, because of their better stability and because of their larger emitting surfaces. Moving plasma shells (i.e., shells which expand or diverge and contract or converge) can turn out to be more convenient, particularly in the case in which discharges are ignited in an active medium. Moving shells are more convenient, in particular, because a diverging plasma shell must be more stable than a steady-state shell since there are no force instabilities. Experimentally, a converging pinch corresponds to a current distribution in a discharge for which $I_0 = 0$, while a diverging pinch corresponds to $I_0 = I_d$.

In this note we report on an experimental study of all three types of discharges: steady-state, converging, and diverging.

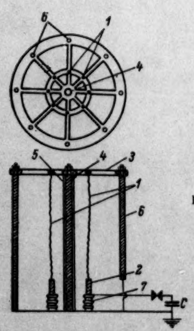

Fig. 1. Two views of the discharge chamber.

2. EXPERIMENTAL APPARATUS AND PROCEDURE

These discharges are produced with devices like that shown schematically in Fig. 1. The wires 1 which are to be exploded are mounted on cylindrical high-voltage electrode 2, which is 80 mm in diameter. The upper electrode 3 can be connected to the "ground" of the capacitor bank by inner copper rod 4, which is enclosed by insulating tube 5, and by eight external metal rods 6 arranged in a circle. The high-voltage electrode is mounted on insulators 7.

In studying steady-state cylindrical shells,[1] we use both inner and outer conductors. To study converging shells we removed the inner rod, and, finally, to study a diverging cylindrical shell we remove the outer conductors.

Under our experimental conditions the length of the discharge gap is varied from 20 to 100 cm.

The chamber is connected to the discharge circuit of a Foton apparatus, described in detail in ref. 4. This apparatus consists of a standard current-pulse generator. The total circuit capacitance is ~500 μF, and the period of the discharge current can be varied from 80 to ~110 μsec, depending on the experimental conditions. The maximum working voltage is 30 kV.

We have studied the typical shape and dimensions of the discharge channel with an SFR-2M ultrahigh-speed camera, recorded the voltage—current characteristics, and studied the overall yield, time behavior, and spectral composition of the discharge radiation. In the current measurements we use two Rogowski loops, one of which goes around the high-voltage electrode and measures the difference current $I_d - I_0$; the second goes around the inner rod and measures the axial discharge current I_0.

The nature and absolute yield of the radiation are studied by the methods described in detail in refs. 4 and 5.

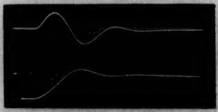

Fig. 2. Typical oscillogram of the axial current I_0 and the voltage across the discharge cap for a steady-state discharge 100 cm long and for a voltage U_0 = 300 kV on the capacitor bank.

3. GENERAL PICTURE OF THE DISCHARGE IN AIR

Breakdown of the discharge gap is initiated by the explosion of eight aluminum wires arranged along generatrices of a cylinder. The energy stored in the capacitor bank is varied, depending on the experimental conditions, from ~22 kJ ($C = 432\ \mu F$, $U_0 = 10$ kV) to 225 kJ ($C \simeq 500\ \mu F$, $U_0 = 30$ kV).

Figure 2 shows a typical oscillogram of the axial current I_0 and the voltage across the discharge gap for an initial bank voltage of 30 kV and for a discharge gap 100 cm long. We see that the discharge, as in the case of a linear pinch,[4] is approximately periodic with a long decay. The length of the first half-cycle of the discharge current is ~50 μsec under these conditions, and the discharge current I_d reaches 310 kA.

Figure 3 shows typical streak photographs of the discharges for the diverging and converging cases. Figure 4 shows a typical streak photograph of a steady-state discharge (a) and enlarged photographs of the discharge at certain stages; from these photographs we clearly see the interaction of the shock waves and the current channels. We also see that all eight of the wires explode essentially simultaneously and that there is a subsequent uniform growth of all the plasma channels.

Over the first 35-40 μsec of the discharges of the Triax type (Fig. 4), all the plasma channels lie at the same radius (the radius at which the wires are attached); then the channels move slowly outward, apparently because the inner return current is higher than the external return

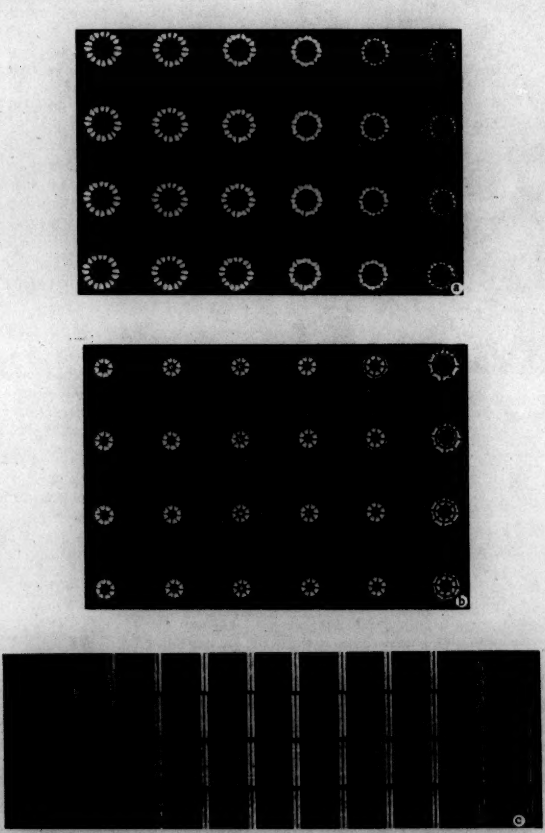

Fig. 3. Typical streak photographs of diverging (a) and converging (b, from the end; and c, from the side) discharges. The discharge length l = 40 cm, the discharge voltage U_0 = 20 kV, and the frames are 1 μsec apart.

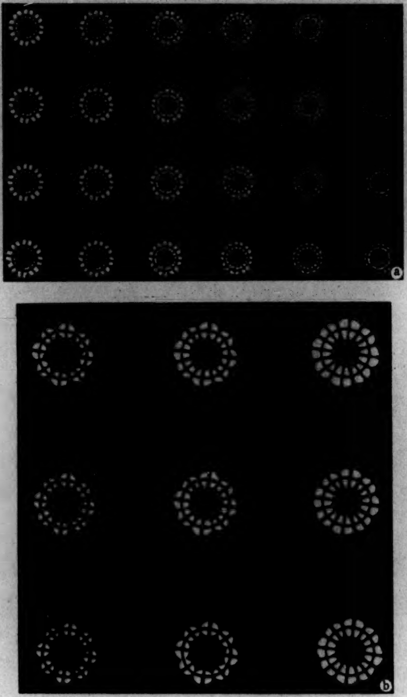

Fig. 4. a) Typical streak photograph of a steady-state discharge, with l = 40 cm and U_0 = 15 kV; b) enlarged photographs of the discharge at 8 and 16 μsec.

current.

In the formation of a converging plasma shell under the influence of the self magnetic fields, the individual discharge channels must move toward the axis of the discharge chamber (as in the skin effect in a discharge in a gas). This motion is observed experimentally, as can be seen from the streak photograph taken from the end of the discharge (Fig. 3b). At first, while the current is low, the discharge is in a steady state; then the channels begin to move toward the center. Near the current maximum the channels reach a velocity of $\sim 10^5$ cm/sec. In the later stages of the discharge, the channels move outward, apparently because of the excess air pressure at the axis, which arises as a result of the collision of shock waves moving toward the center of the chamber.

In the expanding discharge the magnetic field of the axial current causes the discharge channels to diverge (Fig. 3a) from the chamber axis. Under our experimental conditions, the discharge channels interact with each other weakly at this stage.

An extremely curious and important feature of these discharges is that the plasma channels formed by the explosions of the individual wires do not coalesce into a common emitting shell under any experimental conditions, even though an individual channel in free expansion would grow to a radius sufficient to significantly overlap neighboring channels. Furthermore, the plasmoids vigorously oppose the formation of a continuous current shell, undergoing a pronounced deformation. This situation is particularly evident on the streak photographs taken from the end (Fig. 4b) and the streak photographs taken from the side of the converging discharge (Fig. 3c). These photographs show that when different current channels touch, they continue to expand in the radial direction but stop expanding in the azimuthal direction (along the ring electrode); thereafter there is a regularly shaped, linear (along the radius) nonemitting zone between channels, having a width on the order of a few millimeters. The dynamics of a collision between different channels is interesting. On these photographs we clearly see cylindrical shock waves surrounding the discharge channels. After about 10 μsec, the shock waves collide, and the shock front becomes deformed. The collision of the shock waves does not, however, intensify the emission in the region between the channels, as might be expected; on the contrary, the shock wave is "squeezed out" of the collision region. After about 15 μsec, the boundary between channels becomes a dark, nonemitting region, while this boundary continues to emit quite intensely in regions in which the shock wave can propagate "freely."

4. DYNAMICS OF DISCHARGES WITH A RETURN CURRENT

We now discuss the dynamics of discharge with a return current for the case of discharges 20 cm long. Figure 5 shows the velocity of the axis of the discharge channel, v, as a function of the voltage on the capacitor bank for discharges of various types. These functional dependences are obtained by analyzing the streak photographs.

We see from these photographs that the velocity is a linear function of the voltage for the converging and diverging discharges, but for the steady-state discharge the channel velocity is essentially zero for all bank voltages.

Let us follow the development of a single discharge channel. Figure 6 shows the expansion velocity of the thermal zone of a channel as a function of the voltage on the capacitor bank. We see that as this voltage is increased the expansion velocity of the channel increases; for discharges of the Triax type the expansion velocity of the current zone changes slightly. This functional dependence is strongest for the diverging discharge because in this case the development of the current zones is a better approximation to free motion.

We turn now to the stability of the discharges with return currents. A careful study of the streak photographs of the various types of discharges during essentially the entire first cycle of the discharge current shows that the lateral surface of a discharge remains essentially smooth, without any visible large-scale shape distor-

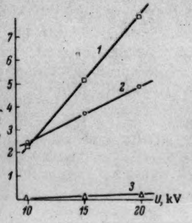

Fig. 5. Velocity of the discharge channel, v, as a function of the initial voltage. Here l = 20 cm. 1) Diverging; 2) converging; 3) steady-state discharges.

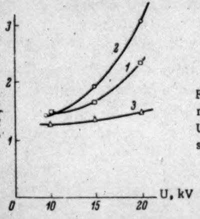

Fig. 6. Expansion velocity of the thermal zone of a channel as a function of U_0. 1) Diverging; 2) converging; 3) steady-state discharges.

tions. The discharge surface displays only a fine-scale ripple; the modulation depth of the lateral surface remains essentially constant throughout the main phase of the process (the first cycle of the discharge current).

5. RADIATION AND ENERGY CHARACTERISTICS

Time sweeps of the discharge spectrum reveal that the discharge emits like an absolute blackbody nearly throughout the first half-cycle of the discharge; this radiation is similar to that of the linear discharge studied in ref. 4. Most of the energy is emitted during this time interval. By the end of the first half-cycle the intensity of the continuous spectrum has fallen off sharply, and the spectrum is a complicated line spectrum.

We determine the brightness temperature of the discharges from the continuous radiation from the central region of the discharge channel. Figure 7 shows the brightness temperature obtained in this manner as a function of the voltage U_0 for various types of discharges; these curves correspond to the first current maximum. We see that the converging discharge is slightly hotter than the steady-state and diverging discharges, under otherwise equal conditions. The discharge temperature increases with increasing U_0, varying over the range ~1.4-2 eV as U_0 is varied from 10 to 20 kV.

Let us consider the energy characteristics for the steady-state discharge. From the voltage–current characteristics we can easily calculate the energy fed to the system over the first half-cycle, Q. For the cases l = 20 cm, U_0 = 20 kV and l = 100 cm, U_0 = 30 kV the values of Q are ~25 and 65 kJ, respectively, i.e., about 30% of the energy stored in the capacitor bank. Figure 8 shows, for these cases, the energy W radiated in various spectral intervals $\Delta\lambda$: over the entire spectral range, $0 < \lambda < \infty$ ($\Delta\lambda_1$); in the transparency band of air, 1860 Å $< \lambda < \infty$ ($\Delta\lambda_2$); and in the ultraviolet, 2200 Å $< \lambda <$ 2700 Å ($\Delta\lambda_3$). The maximum temperatures for these cases are ~2 and 1.5 eV. For this calculation we assume the discharge to have a strictly cylindrical outer surface throughout the entire processes, with a constant temperature equal to the brightness temperature of a discharge channel. It follows from these curves that about 8 and 15 kJ are radiated in these two cases in the transparency band of air during the first half-cycle of the current, i.e., about 30% and 40% of the energy supplied to the discharge, Q. In the ultraviolet region the radiated energy is about 2.5-3 kJ in both cases.

6. DISCUSSION OF RESULTS

We turn first to the circumstance that the plasma channels do not coalesce. In ref. 1 we advanced a hypothesis regarding the nature of this phenomenon, which we can summarize as follows: Because of the sharp density gradients at the boundaries of the shock wave and the thermal zone, a diffusive separation of charges should occur there, and double space-charge shells should form.[6] The interaction of these space charges should cause the shock waves to be "squeezed out" when their fronts collide obliquely, and it should cause a mutual repulsion of the thermal (current) channels. Since the zone between the shock wave and the current channels is transparent for the radiation, this zone is not heated or ionized even after the collision of the current channels; it therefore continues to appear as a nonemitting region on the streak photographs. Some simple calculations support this hypothesis. A potential difference arises over the distance on the order of several mean free paths λ, given in order of magnitude by $\varkappa T/e$. Then we easily find the deviation from quasineutrality δn in this zone, and we find a space charge $q \simeq e\delta n = e(\varkappa T/4\pi e^2\lambda^2)$.

The space-charge double shell can be thought of as a dipole with a dipole moment $q\lambda$, and the interaction of

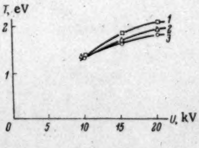

Fig. 7. Brightness temperature at the discharge-current maximum as a function of U_0. 1) Diverging; 2) converging; 3) steady-state discharges.

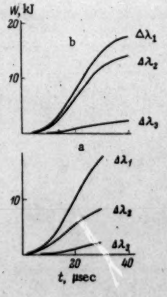

Fig. 8. Energy W emitted in various spectral intervals $\Delta\lambda$ as a function of the time ($\Delta\lambda_1$ = 0-∞, $\Delta\lambda_2$ = 1860 Å-∞, $\Delta\lambda_3$ = 2200-2700 Å). a) l = 20 cm, U_0 = 20 kV; b) l = 100 cm, U_0 = 30 kV.

the boundaries of the current zones can be treated as the interaction of these dipoles. Then the repulsive force between the zone boundaries is on the order of $F = 6q^2\lambda^2/r^4$, where r is the interaction distance. The streak photographs give us a value on the order of 1 mm for r (the thickness of the nonemitting zone between channels). Now expressing λ by the standard equation for the electron mean free path in a completely ionized plasma, and assuming $T \simeq 10^4$ °K and $N \simeq 5 \cdot 10^{18}$ cm^{-3} (ref. 4), we find the interaction force (per unit area) F to be on the order of a few thousand atmospheres. This value is far higher than the hydrodynamic pressure in the thermal zone, which does not exceed a hundred atmospheres. It would clearly be difficult to argue that there are other factors of a hydrodynamic nature which would lead to forces comparable to these electrostatic forces.

The difference between the temperatures in the different types of discharges has an obvious explanation: It is due to the temperature increase resulting from the interaction of different channels. In particular, the increase in the thermal energy during the collapse of the contracting discharge must be on the order of $Mv^2/2$, where M is the mass of the air entrained in the discharge and v is the shell velocity. Estimates show that under our experimental conditions this value is on the order of 0.5 eV, in satisfactory agreement with experiment (Fig. 7).

With regard to a theoretical calculation of the discharge parameters, we note the following: First, no theory exists for cylindrical coaxial discharges at present, and we know of no methods for numerically analyzing two-dimensional problems of magnetic radiative hydrodynamics. Second, during the early stages of the discharges it would be more meaningful to speak of the development of individual linear discharges. However, at the discharge currents in our experiments ($I \leq 300$ kA) the current through a single wire is so low that the lower limit on the applicability of the self-similar theory lies beyond the first half-cycle of the discharge.[4] Naturally, a self-similar calculation here will give temperatures and dimensions for the discharges which are greatly different from the experimental values.

Furthermore, the relative stability of these discharges in comparison with linear discharges[4] apparently shows that, for both vacuum return discharges and atmospheric discharges, the growth rates of the force instabilities are greatly reduced.

Finally, it follows from the data in Sec. 5 on the conversion of the energy supplied to the discharge, Q, into radiated energy $W(\Delta\lambda_2)$ that these discharges have approximately the same conversion coefficients as linear discharges.

The authors thank A. A. Rukhadze, V. S. Komel'kov, and F. A. Nikolaev for discussion of these results.

Zh. Tekh. Fiz., 44, 73-82 (January 1974)

The problem expansion of a spherically symmetric plasma into vacuum is solved on the basis of the equations of hydrodynamics, taking account of recombination and ionization. A numerical solution is given for the expansion of a highly ionized hydrogen plasma. In addition to the rarefaction wave, a "recombination" wave propagates into the plasma. There is a significant "quenching" of the degree of ionization if the initial plasma radius is of the order of the characteristic recombination length. When the initial plasma dimensions are large, recombination during the expansion is essentially complete. The problem of recombination in an expanding carbon plasma is also solved on the basis of the hydrodynamic equations averaged over the volume. The densities of ions X(Z) having various charges Z are found as functions of the time. The asymptotic values of X(Z) are found as a function of the initial plasma dimensions. Ions of a given charge Z can be produced efficiently if the initial plasma dimension is of the order of the characteristic recombination length for ions with charge Z.

INTRODUCTION

A large number of experiments have recently been reported on the expansion of plasmas into vacuum. The basic thrust has been to study the expansion of the plasma produced when a laser pulse strikes the surface of a solid target.[1-3] It has been shown[4] that recombination processes tending to change the charge spectrum of the ions play an important role in the expansion of a laser plasma.

The plasma expands under the influence of pressure and electrical forces. The electrical forces turn out to be important over distances of the order of the Debye length into the plasma from its interface with the vacuum,[5] so electric fields do not affect the motion of most of the material in large plasmas and can thus be neglected.

Recombination in an expanding plasma is studied in refs. 6-8, where certain restrictions are imposed on the gas dynamics of the expansion.

Below, the kinetics of recombination in a freely expanding plasma is analyzed in detail. The system of gas-dynamic equations taking account of inelastic processes is solved. It is shown that the yield of ions having a certain charge Z is a function of the ratio between the initial plasma dimension R_0 and the characteristic recombination length for these ions: At $R_0 \lesssim l_Z$, there is an efficient production of ions with charge less than Z. It is shown that a "recombination wave" propagates along with the rarefaction wave into the interior of a plasma which is initially unperturbed and at ionization equilibrium. Numerical results are reported for hydrogen and carbon plasmas.

STATEMENT OF THE PROBLEM AND BASIC EQUATIONS

We consider a spherically symmetric plasma consisting of neutrals, electrons, and ions of various charges. In writing the equations describing the expansion of the plasma into vacuum, taking account of ionization and recombination, we assume that the velocities of the various parts of the expanding plasma are the same, since the characteristic time required for equalization of the velocities is of the order of the momentum-relaxation times, which are small in comparison with the characteristic times for inelastic processes. We neglect the thermal conductivity. The electron thermal conductivity is negligible if the characteristic length l is large, specifically, if

$$l \gg \frac{6\sqrt{2}\,\pi^{3/2}}{L}\sqrt{\frac{M}{m}}\,(nr_D^3)\,r_D. \qquad (1)$$

Here, L is the Coulomb logarithm, M/m is the ratio of the ion and electron masses, n is the plasma density, and r_D is the Debye length. The ion thermal conductivity is smaller than the electron conductivity by a factor of $\sqrt{m/M}$ and is thus negligible. Below we assume that condition (1) holds. We assume that all the heavy components of the plasma are at the same temperature, but the electron temperature can be different. In fact, the ratio of the characteristic time for three-body recombination (which involves the liberation of energy in an electron gas) to the relaxation time for the electron and ion temperatures is

$$\frac{\tau_{\mathrm{rec}}}{\tau_{ei}} \sim \frac{(4\pi)^2 L}{3}\,\frac{m}{M}\,(nr_D^3)^2. \qquad (2)$$

If ratio (2) is small, the difference between the electron and ion temperatures can be large.

In finding the continuity equations for the various plasma components we take account of

$$A_{Z+1} + e \rightarrow A_Z + h\nu,$$

$$A_{Z+1} + 2e \rightleftarrows A_Z + e + h\nu,$$

where A_Z is an ion of charge Z.

We consider two types of recombination: three-body recombination with an electron as the third particle, and radiative recombination. The energy liberated in the electron capture in three-body recombination appears partially as heat and partially as radiation.[6] Assuming the plasma to be optically thin (estimates of the parameters used in the calculation are given in ref. 9), we assume that this radiation, like the radiation which arises in radiative recombination, is emitted from the gas.

We then find the following initial system of equations:

$$\left.\begin{aligned}
&\frac{\partial n_e}{\partial t}+\frac{1}{r^2}\frac{\partial}{\partial r}(r^2un_e)=A_e(n_Z,\ n_e,\ \Theta,\ T),\\
&\frac{\partial n_Z}{\partial t}+\frac{1}{r^2}\frac{\partial}{\partial r}(r^2un_Z)=A_Z(n_Z,\ n_e,\ \Theta,\ T),\\
&\frac{\partial u}{\partial t}+u\frac{\partial u}{\partial r}=-\left(M\sum_{Z=0}^{Z_m}n_Z\right)^{-1}\frac{\partial P}{\partial r},\\
&\frac{\partial P_e}{\partial t}+u\frac{\partial P_e}{\partial r}+\frac{5}{3}\frac{P_e}{r^2}\frac{\partial}{\partial r}(ur^2)=\frac{2}{3}Q_e,\\
&\frac{\partial P_i}{\partial t}+u\frac{\partial P_i}{\partial r}+\frac{5}{3}\frac{P_i}{r^2}\frac{\partial}{\partial r}(ur^2)=\frac{2}{3}Q_i.
\end{aligned}\right\} \qquad (3)$$

The first two equations in system (3) are the continuity equations for electrons and ions, respectively. The third equation is the equation of motion for a unit volume of the plasma. The last two equations describe the changes in the electron and ion pressures. The quantities A_e, A_Z, Q_e, and Q_i are given by

$$\left.\begin{aligned}
&A_e=n_e\sum_{Z=0}^{Z_m-1}\{n_Z\Gamma_1(Z)-n_{Z+1}\Gamma_2(Z+1)\},\\
&A_Z=n_e\{n_{Z+1}\Gamma_2(Z+1)+n_{Z-1}\Gamma_1(Z-1)\\
&\qquad -n_Z[\Gamma_1(Z)+\Gamma_2(Z)]\},\\
&Q_e=-(\Theta-T)n_e\sum_{Z=0}^{Z_m}n_Z\Gamma_5(Z)+n_e\sum_{Z=0}^{Z_m}n_Z\{\Gamma_4(Z)E_Z^*\\
&\qquad -I(Z)\Gamma_1(Z)-\frac{3}{2}\Theta\Gamma_3(Z)\},\\
&Q_i=(\Theta-T)n_e\sum_{Z=0}^{Z_m}n_Z\Gamma_5(Z).
\end{aligned}\right\} \qquad (4)$$

Here, Θ is the electron temperature, T is the temperature of the heavy particles, I(Z) is the ionization potential of an ion of charge Z [I(0) is the ionization potential of the neutrals], Z_m is the maximum ion charge, and $\Gamma_2 = \Gamma_3 + \Gamma_4$, where Γ_1, Γ_3, and Γ_4 are the coefficients for ionization, radiative recombination, and three-body recombination, respectively. The ionization coefficient is determined from the principle of detailed balance of the ionization and recombination:

$$\Gamma_1=2\left(\frac{2\pi mk}{h^2}\right)^{3/2}\frac{\Theta^{3/2}}{n_e}e^{-\frac{I(Z)}{\Theta}}\Gamma_2(Z+1). \qquad (5)$$

For Γ_3 we use[9]

$$\Gamma_3=2\cdot 10^{-13}\frac{Z^2}{\sqrt{\Theta}}\ . \qquad (6)$$

where θ is in electron volts. For Γ_4 we use[10]

$$\Gamma_4(Z)=\frac{4\pi\sqrt{2\pi}}{9}\frac{Z^3e^{10}}{\sqrt{m}\Theta^{9/2}}n_e. \qquad (7)$$

This equation gives a good approximation to the recombination coefficient at temperatures low in comparison with the ionization potential [$\Theta \ll I(Z)$]*. For example, at $\Theta \sim 10$ eV a carbon plasma consists primarily of high-charge ions (Z = 4), for which condition (*) is satisfied well. There are only a few singly charged ions, for which (7) predicts recombination coefficients which are too high, so the use of (7) at the beginning of the expansion does not lead to a large error. As the plasma expands, the number of singly charged ions increases, but the temperature decreases, so that we can continue to use (7) throughout the expansion stage. The coefficient Γ_5, which represents the relaxation rate of the electron and ion temperatures, is given by

$$\Gamma_5(Z)=\frac{8\sqrt{2\pi}}{3}\frac{\sqrt{m}}{M}e^4L\frac{Z^2}{\Theta^{3/2}}. \qquad (8)$$

Finally, E^*_Z is the energy liberated in the electron gas in a single three-body recombination event:[6]

$$E_Z^*=\begin{cases}6\cdot 10^4 I(Z-1)n_e^{1/6}\Theta^{1/12}, & E_Z^*>\Theta,\\ \Theta & ,\ E_Z^*<\Theta,\\ I(Z-1) & ,\ E_Z^*>I(Z-1).\end{cases}$$

An energy $I(Z-1) - E^*_Z$ is carried away from the plasma as radiation.

We now transform to Lagrange coordinates and introduce dimensionless quantities. We specify the dimensionless time to be $\tau = t/t_0$,

$$t_0=\frac{10^{27}T_0^{9/2}}{8.75n_a^2}$$

is the three-body recombination time, and T_0 and n_a are the initial temperature and density of the heavy particles. The dimensionless coordinate is

$$X=\frac{r}{l_0},$$

where $l_0 = t_0\sqrt{T_0/M}$ is the characteristic recombination length for a singly charged ion.

We convert the temperature, density, and velocity to dimensionless variables by dividing by T_0, n_a and $\sqrt{T_0/M}$, respectively; the result is the following system of equations in terms of dimensionless quantities, which we solve numerically:

$$\left.\begin{aligned}
&\frac{\partial n_a}{\partial\tau}+\frac{n_a}{\rho_0}\left(\frac{X}{R}\right)^2\frac{\partial u}{\partial R}\sum_{Z=0}^{Z_m}n_Z+\frac{2n_au}{X}=A_a,\\
&\frac{\partial u}{\partial\tau}=-\left(\frac{X}{R}\right)^2\frac{\partial P}{\partial R}\frac{1}{\rho_0},\\
&\frac{\partial P_m}{\partial\tau}+\frac{5}{3}P_m\left(\frac{X}{R}\right)^2\frac{\partial u}{\partial R}\sum_{Z=0}^{Z_m}\frac{n_Z}{\rho_0}+\frac{10}{3}\frac{P_mu}{X}=Q_m,\\
&\frac{\partial X}{\partial\tau}=u(R;t),
\end{aligned}\right\} \qquad (9)$$

$$(a=e,\ 0\leqslant Z\leqslant Z_m;\quad m=e,\ i).$$

Here, R is the Lagrange coordinate and $\rho_0 = \sum_{Z=0}^{Z_m} n_Z$ (r; t = 0).

We choose the difference scheme approximating system (9) in the following form:

$$\frac{u_j^{n+1}-u_j^n}{\Delta\tau}=-\left(\frac{X_j^n}{R_j}\right)^2\frac{P_{j+1/2}^n-P_{j-1/2}^n}{\Delta R}\frac{1}{\rho_0},$$

$$\frac{n_{j+1/2}^{n+1}(a)-n_{j+1/2}^n(a)}{\Delta\tau}=A_{j+1/2}^n(a)$$

$$-n_{j+1/2}^n\left\{\left(\frac{X_j^{n+1}}{R_j}\right)^2\frac{1}{\rho_0}\frac{u_{j+1}^{n+1}-u_j^{n+1}}{\Delta R}\right.$$

$$\left.\times\sum_{Z=0}^{Z_m}n_{j+1/2}^n(Z)+2\frac{u_{j+1}^{n+1}+u_j^{n+1}}{X_{j+1}^{n+1}+X_j^{n+1}}\right\},$$

$$\frac{P_{j+1/2}^{n+1}(m)-P_{j+1/2}^n(m)}{\Delta\tau}=Q_{j+1/2}^n(m)$$

$$-\frac{5}{3}P_{j+1/2}^n(m)\left\{\left(\frac{X_j^{n+1}}{R_j}\right)^2\frac{u_{j+1}^{n+1}-u_j^n}{\Delta R}\right.\quad\times$$

$$\times \frac{1}{\rho_0}\sum_{Z=0}^{Z_m} n^n_{j+1/2}(Z) + 2\frac{u^{n+1}_{j+1} + u^{n+1}_j}{X^{n+1}_{j+1} + X^{n+1}_j}\Bigg\},$$

$$X^{n+1}_j = X^n_j + u^{n+1}_j \Delta t. \qquad (10)$$

The condition for the stability for system (10) is found in the standard manner (by the Fourier-series method) to be

$$\Delta t < \sqrt{\frac{3}{5}}\left(\frac{R}{X}\right)^2 \frac{\rho_0 \Delta R}{\left(P\sum_{Z=0}^{Z_m} n_Z\right)^{1/2}}. \qquad (11)$$

Condition (11) results from a dispersion analysis of system (10). The terms due to collisions are discarded. However, in a numerical calculation the step chosen on the basis of condition (11) turns out to be too large, causing a rapid loss of accuracy. For example, the quantities A(α) in the continuity equations can be large, while the changes in n(α) over a time step must be small. The step chosen on the basis of condition (11) is not always satisfactory here. We have therefore worked out the following procedure for choosing a step: First we choose the step so that the changes in all quantities over the time step are small. Then we use condition (11) and, finally, choose the step which is the smaller of the two. We note that the step is determined from (11) in the later stage of the expansion, when inelastic processes have been essentially "frozen."

The accuracy of the numerical calculations is checked on the basis of conservation of the total energy:

$$4\pi\int_0^{R(t)} r^2 dr\left\{\sum_{Z=0}^{Z_m}\frac{u^2 n_Z}{2} + \frac{3}{2}(P_e + P_i)\right\} - 4\pi\int_0^t dt'\int_0^{R(t')} r^2 dr\,(Q_e + Q_i), \qquad (12)$$

where R(t) is the plasma radius at time t. We also calculate the total number of heavy particles, which must also be conserved. Finally, the quasineutrality of the expanding plasma must not be violated in the calculation. We note that in all calculation runs these quantities are conserved quite well.

To conclude this section we state the boundary conditions and write the equations used to calculate the initial ionization state of the plasma at specified values of the temperature and the heavy-particle density.

The boundary conditions for system (10) are

$$u^n_{j=0} = 0, \quad P^n_{J+1/2} = 0, \quad n^n_{J+1/2} = 0.$$

The first condition reflects the circumstance that the plasma velocity vanishes at the center of the plasma. The last two conditions correspond to conditions at the free boundary.

We assume that the plasma is initially in ionizational equilibrium; this is a legitimate assumption since the time required for the establishment of an ionization equilibrium is only a few nanoseconds,[9] which is shorter than the laser pulses used in the experiments of refs. 1-4 (50-100 nsec). It follows from the condition for ionization equilibrium that the right side of the first equation in (3) vanishes initially, so that

$$\sum_{Z=0}^{Z_m}\{n_Z\Gamma_1(Z) - n_{Z+1}\Gamma_2(Z+1)\}\big|_{t=0} = 0, \qquad (13)$$

which, along with the neutrality condition, makes it possible to calculate the initial ionization state on the basis of equations derived from Eq. (13):

$$\left.\begin{aligned} n_Z &= n_0\prod_{k=1}^{k=Z}\frac{\Gamma_1(k-1)}{\Gamma_2(k)};\quad n_0 = n_a\left[1 + \sum_{k=1}^{k=Z_m}\prod_{i=1}^{k}\frac{\Gamma_1(i-1)}{\Gamma_2(i)}\right]^{-1},\\ n_e&\left[1 + \sum_{k=1}^{Z_m}\prod_{i=1}^{i=k}\frac{\Gamma_1(i-1)}{\Gamma_2(i)}\right] = \sum_{k=1}^{Z_m} k\prod_{i=1}^{i=k}\frac{\Gamma_1(i-1)}{\Gamma_2(i)}\,n_a.\end{aligned}\right\} \qquad (14)$$

Calculations on the basis of Eqs. (14) are carried out on a computer.

EXPANSION OF A HYDROGEN PLASMA

In this section we describe a numerical solution of the system of difference equations (10) for a hydrogen plasma. The plasma is assumed to have an initial radius of R_0.

The densities of all particles, the temperature, and the pressure are assumed to be homogeneous along the radius. The initial plasma temperature chosen for the calculation is T_0 = 9 eV. The number of heavy particles per unit volume is chosen to be $n_a = 10^{19}\ \text{cm}^{-3}$. The initial charged-particle density, calculated from Eq. (14), is $n_e = 0.994 n_a$. Accordingly, we begin with a highly ionized plasma. The results reported here correspond to runs differing in the initial radius R_0. In the first run we use $R_0 = 10 l_0$, and in the second we use $R_0 = l_0$; we find the solutions for these two cases to differ qualitatively. The most important result is that in the case of the expansion of the smaller sphere there is an appreciable "quenching" of the degree of ionization. Increasing the radius by a factor of 10 results in a nearly complete recombination (Fig. 1). Figures 2 and 3 show the space–time distributions of the plasma parameters. During the expansion a spherical rarefaction wave propagates from the vacuum boundary toward the center of the plasma at a nearly constant velocity. We note that in the case of an adiabatic expansion the velocity in the rarefaction wave

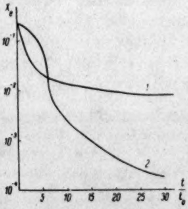

Fig. 1. Degree of ionization as a function of the time. 1) $R_0 = l_0$; 2) $R_0 = 10 l_0$.

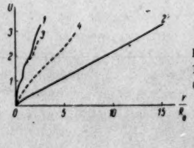

Fig. 2. Radial profile of the velocity. 1,2) $R_0 = l_0$; 3,4) $R_0 = 10 l_0$; t: 1) $0.57 t_0$; 2) $4.78 t_0$; 3) $5.38 t_0$; 4) $17.8 t_0$.

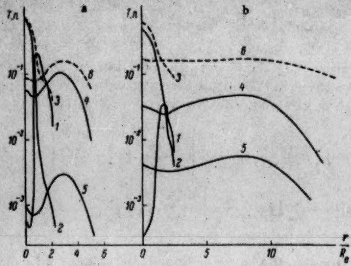

Fig. 3. Radial profiles of the temperature and densities at various times. a: $R_0 = 10 l_0$; $t = 5.38 t_0$ [1) $n_{Z=0}/n_a$; 2) $n_{Z=1}/n_a$; 3) T/T_0]; $t = 17.8 t_0$ [4) $10^2(n_{Z=0}/n_a)$; 5) $10^2(n_{Z=1}/n_a)$; 6) $10^2(T/T_0)$]. b: $R_0 = l_0$; $t = 0.57 t_0$ [1) $n_{Z=0}/n_a$, 2) $n_{Z=1}/n_a$, 3) T/T_0]; $t = 4.5 t_0$ [4) $10^2(n_{Z=0}/n_a)$, 5) $10^2(n_{Z=1}/n_a)$, 6) $10^2(T/T_0)$].

is an essentially linear function of the radius until the rarefaction reaches the center of the plasma; the linear functional dependence at the periphery of the plasma is retained at all values of t. We see from Fig. 2 that this functional dependence becomes nonlinear during the expansion of a recombining plasma; the asymptotic boundary velocity is larger for the plasma with the smaller initial radius. The calculated results show that this difference is due to the large relative loss (per particle) to radiation in the case of the plasma with the larger radius.

During the gas-dynamic expansion the local ionizational equilibrium is disrupted. A "recombination wave" propagates into the plasma behind the rarefaction front. The propagation velocity of this wave is lower than that of the rarefaction wave and decreases toward the center. Obviously, the characteristic delay time of the recombination after the rarefaction must be on the order of the time for disruption of the local ionizational equilibrium, which is a function of the rate of change of the gas-dynamic quantities (Θ and n). Figure 3 (curves 1) shows the boundary of the recombination wave; at this time the rarefaction wave has already reached the center. Behind the rarefaction front the ionization energy is efficiently converted into radiation and thermal energy, liberated in three-body recombination in the electron gas. The result is a bending of the curves showing the electron temperature behind the recombination front (curves 3). The density of neutrals ahead of the recombination front is reduced slightly because of the rarefaction, and it increases sharply (by two or three orders of magnitude) at the front. Behind the front the neutral density falls off because of expansion. In the later stages of the expansion the minima in the densities and temperature in the central region can be attributed to the conditions governing the reflection of the rarefaction wave from the center.

EXPANSION OF A CARBON PLASMA WITH SPECIFIED VELOCITY, DENSITY, AND TEMPERATURE PROFILES

We turn now to the expansion of a plasma containing ions of various charges. We use the procedure suggested by Mattioli,[8] by which we can convert the system of partial differential equations in (3) to a system of ordinary differential equations. We assume the temperatures and densities of the charged particles to be distributed uniformly along the radius. We write the velocity and density of the heavy particles as functions of the coordinate in the following manner:

$$\left.\begin{aligned} u(r;\, t) &= \dot{R}\xi, \\ \sum_{Z=0}^{Z_m} n_Z &= n_a\left[\frac{R_0}{R(t)}\right]^3 e^{-\xi^2}, \end{aligned}\right\} \qquad (15)$$

where $\xi = r/R(t)$, and R(t) is the instantaneous radius of the plasma–vacuum boundary.

Integrating system (3) over the plasma volume, and using (15), we find a system of ordinary differential equations for the temperatures, the charged-particle densities X_e and X_Z, and the radius R(t):

$$\frac{dX_e}{d\tau} = \bar{A}_e;\quad \frac{dX_Z}{d\tau} = \bar{A}_Z,$$

$$\frac{d^2R}{d\tau^2} = \frac{T + X_e\Theta}{R}\gamma_6^2,$$

$$\frac{3}{2}\frac{d(\Theta X_e)}{d\tau} + 3\frac{\Theta X_e}{R}\frac{dR}{d\tau} = \bar{Q}_e,$$

$$\frac{3}{2}\frac{dT}{d\tau} + 3\frac{T}{R}\frac{dR}{d\tau} = \bar{Q}_i.$$

Here we have used

$$\bar{A}_e = \frac{X_e}{R^3}\sum_{Z=0}^{Z_m}\{X_Z\bar{\Gamma}_1(Z) - X_{Z+1}\bar{\Gamma}_2(Z+1)\},$$

$$\bar{A}_Z = \frac{X_e}{R^3}\{[X_{Z+1}\bar{\Gamma}_2(Z+1) + X_{Z-1}\bar{\Gamma}_1(Z-1)]$$

$$- X_Z[\bar{\Gamma}_2(Z) + \bar{\Gamma}_1(Z)]\},$$

$$\bar{Q}_e = -\bar{Q}_i + \frac{X_e}{R^3}\sum_{Z=0}^{Z_m}\{\bar{E}_Z\bar{\Gamma}_4(Z) - I(Z)\bar{\Gamma}_1(Z) - \frac{3}{2}\Theta\bar{\Gamma}_3(Z)\},$$

$$\bar{Q}_i = (\Theta - T)\frac{X_e}{R^3}\sum_{Z=0}^{Z_m} X_Z\bar{\Gamma}_5(Z).$$

The transformed quantities are

$$\bar{\Gamma}_1 = \gamma_1\frac{Z^3}{\Theta_3}e^{-\frac{I(Z)}{\Theta}},\quad \bar{\Gamma}_2 = \bar{\Gamma}_3 + \bar{\Gamma}_4,$$

$$\bar{\Gamma}_3 = \gamma_3\frac{Z^2}{\Theta^{1/2}},\quad \bar{\Gamma}_4 = \gamma_4\frac{Z^3}{\Theta^{9/2}}\frac{X_e}{R^3},$$

$$\bar{\Gamma}_5 = \gamma_5\frac{Z^2}{\Theta^{3/2}},$$

$$\bar{E}_Z = \begin{cases} \gamma_6 I_{Z-1}\dfrac{X_e^{1/6}\Theta^{1/12}}{R^{1/2}}, & \bar{E}_Z > \Theta, \\ \Theta, & \bar{E}_Z < \Theta, \\ I(Z-1), & \bar{E}_Z > I(Z-1). \end{cases}$$

In system (9) we have introduced the dimensionless time $\tau = t/\tau_0$, where $\tau = R_0\sqrt{M/T_0}$ is the characteristic expansion time. The coefficients γ are the ratios of τ_0 to the characteristic times for the corresponding processes at t = 0:

$$\gamma_1 = 2^{-3/2}\frac{\tau_0}{\tau_1},\quad \gamma_3 = 2^{-3/2}\frac{\tau_0}{\tau_3},\quad \gamma_4 = 3^{-3/2}\frac{\tau_0}{\tau_4},\quad \gamma_5 = 2^{-3/2}\frac{\tau_0}{\tau_4}.$$

We also have $\gamma_6 = a\, n_a{}^{1/6}\Theta_0{}^{1/12}$, where $a = 6\cdot 10^{-4}$. The initial ionization state of the plasma is determined

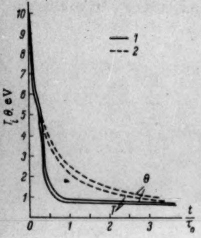

Fig. 4. Electron and ion temperatures as functions of the time. 1) $R_0 = 10^{-2}$, 2) $5 \cdot 10^{-2}$ cm.

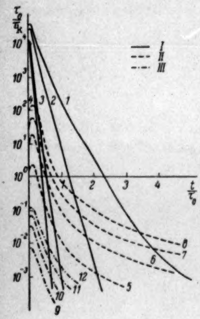

Fig. 5. Characteristic frequencies of inelastic processes. I) Ionization; II) three-body recombination; III) radiative recombination. 1) Z = 0; 2,5,9) 1; 3,6,10) 2; 4,7,11) 3; 8,12) 4.

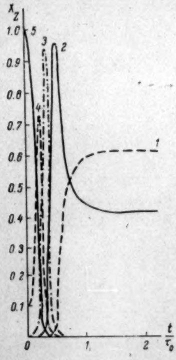

Fig. 6. Densities X_Z of ions of various charges as functions of the time. 1-5) Z = 0, 1, 2, 3, 4, respectively.

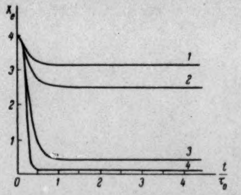

Fig. 7. Degree of ionization of the plasma, X_e, as a function of the time for various values of the ratio R_0/l_0. For all the calculations the recombination length of singly charged ions is $l_0 \approx 3.3 \cdot 10^{-2}$ cm. The initial plasma radius R_0 is: 1) $\sim 10^{-3}$; 2) $\sim 10^{-2}$; 3) $\sim 5 \cdot 10^{-2}$; 4) $\sim 10^{-1}$.

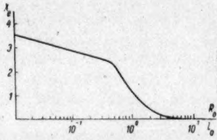

Fig. 8. Asymptotic value of X_e as a function of the initial plasma dimension.

from Eqs. (14) for a carbon plasma with $\Theta_0 = 10$ eV and $n_a = 10^{19}$ cm^{-3}. This plasma turns out to consist primarily of ions with Z = 4. The initial boundary velocity is assumed to be zero. We have carried out several calculation runs, varying the initial plasma dimensions. During the expansion the electron and ion temperatures fall off. For the plasma having the smaller initial radius, the temperature falls off smoothly as a function of the time (Fig. 4). For the plasma with the larger initial radius, recombinational heating and radiation are more important; there are kinks in curves 3 and 4 because of the pronounced deviation from adiabaticity. The difference between the electron and ion temperatures for given values of Θ_0 and n_a turns out to be small, because ratio (2) is large in comparison with unity. We see from Fig. (5) that the characteristic ionization frequency (curve 1) falls off as a function of the time—more rapidly, the larger Z. This decrease is a result of the exponential functional dependence of the ionization frequency on $I(Z)/\Theta$.

The rate of three-body recombination (which is the most probable type of recombination under these conditions) is a power function of the density and temperature, and for ions of different charges this rate falls off in approximately the same manner. During the initial stage of the expansion there is some increase in the recombination probability because of the temperature drop. The density decrease is not influential in this stage. The recombination probability subsequently falls off because of the density decrease. Because of the different rates at which the probabilities for recombination and ionization decrease, the ionization equilibrium is disrupted at different times for ions of different charges, e.g., the intersection of curves 1 and 3 shifts toward earlier times with increasing Z. Figure 6 illustrates the recombination kinetics during the expansion. During the inertial stage of the expansion, the ion density is "quenched." For this version of the calculation it is primarily singly charged ions and neutrals which are left.

Figure 7 shows the degree of ionization of the plasma as a function of the time for various initial radii. We see that the "quenching" occurs over a time $\tau_0 \sim R_0 \sqrt{M/T_0}$ (the characteristic expansion time). At $t > \tau_0$ the role of recombination becomes inconsequential. As the initial radius is reduced, the ultimate degree of ionization increases: For $R_0 = 3.5 l_0$ it is about 0.1, while for $R_0 = 0.35 l_0$ it is 2.5. Interestingly, the ultimate degree of ionization has a functional dependence on the initial radius such that X_e falls off rapidly as a function of R_0 near the characteristic recombination length l_0 (Fig. 8). For $R_0 > l_0$ the degree of ionization is small in comparison with unity; for $R_0 < l_0$ the final degree of ionization can exceed unity. This situa-

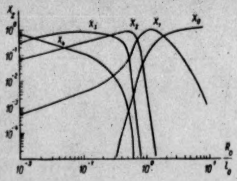

Fig. 9. Final densities as functions of R_0/l_0.

tion is clearly evident from Fig. 9, which shows the final densities of the ions of various charges as functions of R_0.

The yield of, e.g., doubly charged ions from the plasma can be increased by using an initial plasma radius of the order of $0.1l_0$; this radius evidently corresponds to the recombination length for doubly charged ions: The ratio of the recombination lengths of ions of different charges, according to (7), is

$$\frac{l_0(Z_1)}{l_0(Z_2)} \sim \left(\frac{Z_2}{Z_1}\right)^3,$$

and the efficient production of ions having a large charge would require a small initial plasma radius.

Zh. Tekh. Fiz., 44, 83-90 (January 1974)

An experimental study has been made of the spatial characteristics of the plasma produced by the interaction of a high-current electron beam with a dense gas target in the center of a magnetic mirror. The average plasma dimensions and the radial profile of the density in the transverse cross section have been determined by probing the plasma at λ = 4 and 8 mm. These measurements yield the radial dimensions of the plasma column, the spatial profile of the plasma density, the total number of particles per unit length of the trap, and the degree of ionization of the plasma. It is concluded on the basis of these results that the most important mechanism for plasma loss from the trap during the active period of the discharge is loss of plasma in the mirror.

We have previously studied[1,2] the production and heating of plasmas at densities 10^{14}–10^{15} cm^{-3} in the interaction of a high-current electron beam with a dense gas target at the center of an open magnetic trap. We feel it worthwhile to determine the spatial distribution of this plasma for various discharge conditions; this information yields the maximum dimension of the plasma column, the total number of particles in the trap, and the degree of ionization of the plasma. This information can also furnish information on the production and heating of the dense plasma and can be used to evaluate the plasma loss across and along the magnetic field.

The experiments are carried out on the VGL-2 device.[1] The average plasma dimensions and the radial profile of the density in a cross section are determined by microwave probing at λ = 4 and 8 mm. During the active period of the discharge the plasma is usually opaque at these wavelengths. We therefore study the spatial characteristics of the plasma on the basis of the phase shift of the reflected signals or by measuring the phase shift of the reflected wave at one wavelength and determining the maximum density from the cutoff at other wavelengths. In several experiments a fixed double electrostatic probe is used to check the transverse dimensions.

Writing the radial profile of the density as

$$N(r)=N_{\max}\left[1-\left(\frac{r}{r_{\max}}\right)^{\gamma}\right] \qquad (1)$$

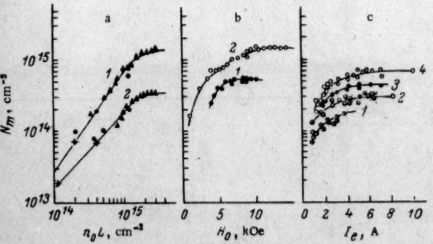

Fig. 1. Maximum plasma density as a function of: a) the neutral-gas density; b) the magnetic field; and c) the electron-beam current. a: H_0 = 5 kOe. 1) E_e = 30; 2) 15 keV. b: E_e = 30 keV. 1) $n_0L = 5 \cdot 10^{14}$; 2) $1 \cdot 10^{15}$ cm^{-2}. c: H_0 = 5 kOe, $n_0L = 8 \cdot 10^{14}$ cm^{-2}. 1) E_e = 9; 2) 15; 3) 22.5; 4) 30 keV.

and assuming that the phase of the reflected wave at a given time carries information about the position of the critical density for the given wavelength, we can write the maximum plasma radius, $r_{\max}$, and the exponent γ as

$$\left.\begin{aligned} r_{\max}&=r_1(1-S_1)^{-\frac{\lg r_1 r_2}{\lg\frac{1-S_1}{1-S_2}}}=\frac{r_1}{(1-S_1)^{1/\gamma}},\\ \gamma&=\lg\frac{1-S_2}{1-S_1}\lg\frac{r_1}{r_2}=\frac{\lg\frac{1-S_2}{1-S_1}}{\lg\frac{r_2}{r_1}},\end{aligned}\right\} \qquad (2)$$

where $S_{1,2} = N(r_{1,2})/N_{\max}$, $r_{1,2}$ are the radii of the reflecting layer for λ_1 and λ_2, respectively, and $N_{\max}$ is the maximum plasma density. The values of r_1 and r_2 are found from the phase of the reflected wave:[2]

$$\varphi=2\frac{\omega}{c}\int\limits_0^r\sqrt{1-\frac{N(r)}{N_{\text{cr}}}}\,dr-\frac{\pi}{2}. \qquad (3)$$

Since the outer boundary of the plasma is not determined in these experiments, we assume an axisymmetric distribution with a maximum at the axis and measure the phase shift from the time at which the critical density decays at the axis; in the transition layer, function (1) is extrapolated as a piecewise-linear function. Then,

$$r_{1,2}=\frac{3}{8}\lambda m_{1,2}, \qquad (4)$$

where $m_{1,2} = \varphi_{1,2}/\pi$ is the number of periods in the phase of the reflected signal corresponding to the motion of the reflecting layer from the axis to $r_{1,2}$.

If we can assume the function $N = f(r)$ to be fixed over a certain time interval, we can determine r_1 and r_2 from the phase shift of one reflected wave at different times. This method has been used previously.[3] Instead of using the average density, however, we use the known maximum density and simplify the calculation by means of this assumption regarding the radial distribution. In this case $N(r_1) = N(r_2)$ in Eq. (2), corresponding to the position of the reflecting layer for one wavelength at different times, for which the maximum densities are also different.

We have studied the spatial characteristics of the plasma produced by the electron beam at a beam energy $E_e \le 30$ keV, a beam current $I_e \le 20$ A, and an injection time ~ 400 μsec. Microwave horns are placed in the annular slit at the center of the mirror system ($R = H_{ml}/H_0 = 1.5$), as in ref. 1, and the phases of waves at $\lambda = 4$ and 8 mm reflected and transmitted by the plasma are measured. Maximum densities above $7 \cdot 10^{13}$ cm^{-3} are determined from the double-probe current as calibrated on the basis of the results of microwave and particle measurements. Figure 1 shows typical functional dependences of the maximum plasma density in the discharge on the discharge parameters.

Analyzing the oscillograms of the reflected microwave signals at $\lambda = 4$ and 8 mm in accordance with Eq. (4), we find the radius of the plasma column for several values of the density as a function of various discharge parameters: the neutral-gas density, the magnetic field at the center of the trap, and the energy and current of the electron beam interacting with the plasma (Figs. 2, 3). On the basis of these experimental functional dependences and Eqs. (1) and (2) we find the analogous functional dependences for the maximum plasma radius (shown in the same figures). The results are as follows.

1. The transverse dimension of the plasma column increases with increasing neutral-gas density; the rate of increase is faster for the layers having the lower plasma densities. The maximum plasma radius increases with increasing neutral-gas density only up to $n_0L \le 2 \cdot 10^{15}$ cm^{-2} and is 10-15 times larger than the beam radius.

2. As the magnetic field at the center of the trap is increased ($H_0 > 1.5$ kOe), the radii of plasma layers at the same density decrease. As the density is raised, the decrease in the transverse dimensions becomes less apparent, i.e., stronger magnetic fields are required to achieve the same contraction of the plasma column.

3. Examination of the behavior of the transverse plasma dimensions for various electron-beam currents reveals that when the current is reduced from 10-12 to 2 A, the value of r changes slightly. With a further decrease in I_e the plasma column contrasts rapidly. This behavior is a result of the conditions governing the formation of the dense plasma.[1] Increasing the beam energy leads to an increase in the radial dimensions over the entire range of neutral-gas densities. The values of r_{max} found at the two wavelengths for a given time and found from a single wavelength at different times are very nearly equal (curves 3 and 4 in Fig. 2).

From the experimental data in Figs. 2-4 and from Eqs. (1) and (2) we find the spatial profiles of the plasma density in a radial cross section of the plasma column (Figs. 4 and 5); the results agree with the results of the probe measurements (curve 4 in Fig. 5). We find that at low neutral-gas densities ($n_0L < 10^{14}$ cm^{-2}) the profile is described approximately by a quadratic parabola. As the neutral-gas density is increased, the region in which the plasma is most dense contracts, becoming only 1.5-2 times as large as the region filled by the electron beam. The density gradients dN/dr increase at high neutral-gas densities and decrease at low densities. At small values of n_0L the density gradients vary smoothly.

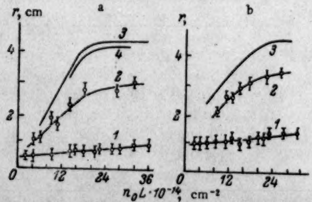

Fig. 2. Transverse dimensions of the plasma column as a function of the neutral-gas density for various plasma densities. t = 300 μsec. a) E_e = 15; b) 22.5 keV. 1) $N \ge 7 \cdot 10^{13}$; 2) $\ge 1.8 \cdot 10^{13}$; 3, 4) 0 cm^{-3}.

In weak magnetic fields ($H_0 \le 3$ kOe) the profile $N = f(r)$ is approximately uniform (curves 1-3 in Fig. 5), with a large density gradient near the trap wall. In stronger fields ($H_0 > 4$ kOe) the profile becomes a decaying profile with a large density gradient over the entire radius. At these field values the efficiency of plasma heating increases.[2] The relation between the shape of the profile and the heating efficiency can be explained on the basis of a hybrid resonance,[4] because with a gently sloping density profile (curve 4 in Fig. 5) the conditions in the layers having large radial dimensions are such that the frequencies of the waves excited in the plasma correspond to the frequency of the upper hybrid [$\overline{\omega} = \Omega(r)$]. In the case of a uniform or approximately uniform density profile this resonance condition is not satisfied, since the magnetic field is homogeneous within 5% over the plasma radius.

From the radial profiles of the plasma density we can evaluate the total number of plasma particles per unit length of the trap:

$$N_{\text{totl}} = \int_s N(S)\, dS(r). \tag{5}$$

Substituting Eq. (1) for N(r) into Eq. (5) and setting $dS = 2\pi r dr$, we find

$$N_{\text{totl}} = \pi N_{\max} r_{\max}^2 \frac{\gamma}{\gamma + 2}. \tag{6}$$

Figures 6 and 7 show the total number of particles per unit length of the trap as a function of the discharge parameters. We see that as the gas density increases, the total number of plasma particles increases over the entire range of densities n_0L, up to $3 \cdot 10^{15}$ cm^{-2} at a beam energy of 30 keV. At lower energies the increase in N_{totl} is

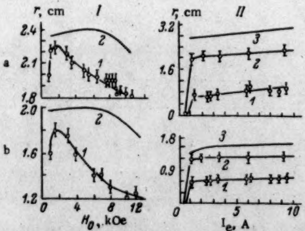

Fig. 3. Transverse dimensions of the plasma column as a function of the magnetic field (I) and of the current of the electron beam injected into the trap (II). I: 1) $N = 7 \cdot 10^{13}$; 2) 0 cm^{-3}. II: 1) $\ge 7 \cdot 10^{13}$; 2) $\ge 1.8 \cdot 10^{13}$; 3) 0 cm^{-3}. a) t = 300; b) 500 μsec.

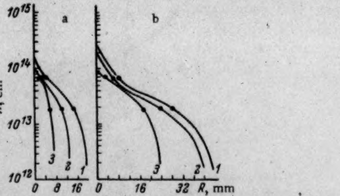

Fig. 4. Spatial profile of the plasma density for various neutral-gas densities at various times. a) $n_0L = 8 \cdot 10^{14}$; b) $1.35 \cdot 10^{15}$ cm^{-2}. 1) t = 300; 2) 400; 3) 500 μsec. E_e = 15 keV.

cut off at only $n_0L \simeq 2 \cdot 10^{15}$ cm^{-2}, apparently because the ionization coefficient of the plasma is less than unity for a given energy input into the discharge at values $n_0L > 2 \cdot 10^{15}$ cm^{-2}. Increasing the beam energy leads to an increase in the total number of particles and leads to complete ionization of the plasma. By measuring the total number of plasma particles and the radial profile of the neutral-gas density in the same cross section of the trap before the electron beam is injected we can determine the average charge of the argon ions in the discharge, since the time characteristic of ionization and the production of a dense plasma is shorter than the characteristic transit times of slow atoms across the moving gaseous target. Using the function[5] $n_0 = f(r)$ we can determine the total number of neutral particles per unit length of the trap through numerical integration. The average ion charge $\overline{Z}$ is defined as the ratio of the total number of plasma electrons to the total number of neutral particles under the condition $N_i = n_0$. Our calculations show that $\overline{Z}$ varies from 1.2 to 3.5 for a neutral-gas density of $n_0L = 8.4 \cdot 10^{14}$ cm^{-2} as the electron beam energy is raised from 15 to 30 keV. The observed values $\overline{Z} > 1$ are due to multiple ionization of argon atoms.

It follows from the function $N_{totl} = f(H_0)$ that in weak magnetic fields the total number of particles increases markedly with increasing field. At $H_0 > 3$ kOe the total number of particles per unit length varies only slightly in the central part of the trap. As the beam current is increased, this number increases, implying an increase in the value of Z for the plasma particles; this increase can in turn be attributed to an increase in the efficiency of the plasma heating with increasing electron-beam power (or current) since N_{totl} is a nonlinear function of $W_e = I_eE_e$.

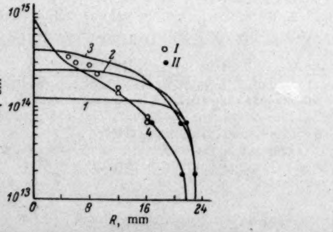

Fig. 5. Spatial profile of the plasma density for various magnetic fields at the center of the trap. 1) H_0 = 1; 2) 2; 3) 4; 4) ≥ 10 kOe. I) Experimental points obtained with a calibrated double electrostatic probe; II) obtained from microwave measurements.

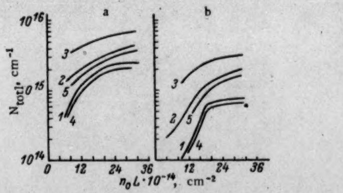

Fig. 6. Total number of particles per unit length of the trap as a function of the neutral-gas density. a) t = 300; b) 500 μsec. 1, 4) E_e = 15; 2, 5) 22.5; 3) 30 keV. 1, 2) Obtained at two wavelengths; 3-5) at a single wavelength.

On the basis of the data on the total number of particles in the trap we can write a balance equation for the particles in the trap during the active period of the discharge:

$$\frac{dN}{di} = \langle \sigma_e v_e \rangle n_0 N_e - \alpha_R N_e N_i - D_\perp \nabla^2 N_e - D_\parallel \nabla^2 N_e, \tag{7}$$

where n_0 is the neutral-gas density, N_e and N_i are the electron and ion densities, α_R is the recombination coefficient, and $D_\perp$ and $D_\parallel$ are the effective diffusion coefficients.

The total rate of particle loss from the trap, calculated from Figs. 3, 4, and 7, taking account of the transverse cross section of the plasma, is $(dN)/(dt) = 2 \cdot 10^{18}$ cm$^{-3} \cdot$ sec^{-1}. The first term on the right side of Eq. (7) gives the increase in the number of particles in the trap due to ionization of new gas supplied to the discharge; in the case of complete ionization of the gas, this term can be defined as

$$\langle \sigma_e v_e \rangle n_0 N_e = \frac{dn_0}{dt} = \eta q, \tag{8}$$

where q is the total amount of gas fed to the entrance of the collimating device which collimates the gas flow, and η is its gas efficiency, which has been determined previously[6] for various flow rates q. The other terms in Eq. (7) give the particle loss due to recombination and diffusion across and along the magnetic field. The effects of the individual terms in Eq. (7) are examined in the case

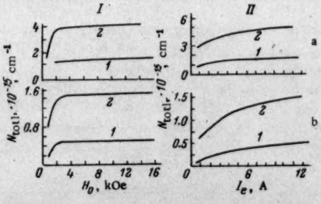

Fig. 7. Total number of particles per unit length of the trap as a function of the magnetic field (I) and of the electron-beam current (II). 1) E_e = 22.5; 2) 30 keV. a) t = 300; b) 500 μsec.

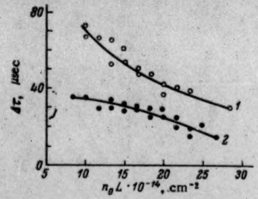

Fig. 8. Time required for the plasma to flow between the center of the trap and the mirror as a function of the neutral-gas density. 1) E_e = 15; 2) 30 keV.

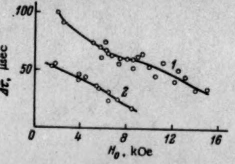

Fig. 9. Time required for the plasma to flow between the center of the trap and the mirror as a function of the magnetic field. 1) E_e = 15; 2) 30 keV.

of efficient heating of the plasma electrons,[2] e.g., with $E_e = 30$ keV, $n_0L = 8 \cdot 10^{14}$ cm^{-2}, $H_0 = 12$ kOe, $q = 22.6$ cm^3/sec, and $\eta = 0.1$. Here the plasma density is $4 \cdot 10^{14}$ cm^{-3}, its electron temperature is 1 keV, the average ion energy is ~ 90-100 eV, and the rate of ionization of the particles is $\eta q \approx 6 \cdot 10^{19}$ cm^{-3} · sec^{-1}. The recombination loss can be neglected since we have $\alpha_R N_e N_i = 4 \cdot 10^{11}$ cm^{-3} sec^{-1} at these plasma parameters.

The transverse-diffusion coefficient can be evaluated from the change in the radial density profile after the plasma is produced: We find $D_\perp = r^2/4t \simeq 2 \cdot 10^2$ cm^2/sec at 300 μsec after injection. Calculating the radial density gradient from Figs. 4 and 5 or from the radial profile of the plasma density, we find the loss due to diffusion across the magnetic field to be

$$\Delta\Gamma_\perp = D_\perp \nabla^2 N = D_\perp \frac{1}{r}\frac{\partial}{\partial r}\left(r\frac{\partial N}{\partial r}\right). \tag{9}$$

Using Eq. (1) for N in Eq. (9) and differentiating, we find

$$\Delta\Gamma_\perp = -D_\perp \frac{\gamma^2 N_{\max}}{r^{\gamma}_{\max}} r^{\gamma-2}. \tag{10}$$

For a parabolic density profile ($\gamma = 2$) we find $\Delta\Gamma_\perp = 4.7 \cdot 10^{16}$ cm^{-3} · sec^{-1}, and for a profile like that shown by curve 4 in Fig. 5 ($\gamma = 0.274$) we find $\Delta\Gamma_\perp$ $1.2 \cdot 10^{16}$ cm^{-3} · sec^{-1}.

The loss due to the flow of plasma to the mirror is evaluated from

$$\Delta\Gamma_\parallel = \frac{\bar{N} v S}{V}, \tag{11}$$

where $\bar{N}$ is the average plasma density beyond the mirror, v and S are the velocity and cross section of the plasma flow beyond the mirror, and V is the trap volume. To determine the longitudinal velocity component of the plasma moving along the magnetic field, we use a dual microwave interferometer which simultaneously measures the densities at the center of the trap and beyond the mirror. Figures 8 and 9 show the time required for a plasma with $N \geq 7 \cdot 10^{13}$ cm^{-3} to flow between the center of the system and the mirror (a distance of 30 cm) as a function of the neutral-gas density and the magnetic field. It follows from these figures that the plasma velocity varies from $3 \cdot 10^5$ to $2 \cdot 10^6$ cm/sec for the various discharge parameters. The increase in the longitudinal velocity with increasing magnetic field shows that in this beam–plasma discharge there is an increase in the longitudinal component of the energy of the plasma particles as well as in the transverse component,[2] i.e., the mechanisms of both transverse and longitudinal particle acceleration are operating. The increase in $v_\parallel$ with increasing neutral-gas density (or plasma density) is apparently due to an increase in the gas-kinetic pressure of the plasma at constant values of the magnetic field and the electron-beam power.

Taking account of the quantities in Eq. (11), we find that the loss due to the escape of plasma to the mirror is of the order of the total loss.

Accordingly, these measurements have revealed the radial dimensions of the plasma column, the spatial profile of the plasma density, and the total number of particles in the trap. From these results we conclude that the loss of plasma in the mirror is responsible for the total loss of plasma from the trap during the active period of the discharge.

By simultaneously solving the Boltzmann kinetic equation and the energy balance equation we obtain the electron energy distribution function, the electron temperature, and other parameters of a microwave-discharge plasma in the skin layer. The kinetic equation takes account of the influence of the magnetic field, electron–electron collisions, and elastic and inelastic collisions. The experimental values of the electron density and gas temperature in a discharge excited in argon by a 3-cm band source are used for the numerical calculations. The results are compared with the experimental data.

INTRODUCTION

In connection with possible important practical applications,[1-4] interest has recently increased in gas discharges excited by rapidly alternating electromagnetic fields. This type of discharge is being investigated experimentally. The theory of a stationary microwave gas discharge is not well developed; there are essentially no kinetic analyses of this type of discharge, apart from refs. 5 and 6, in which the influence of elastic and inelastic collisions on the electron energy distribution function has been investigated. An analysis of the experimental data shows that it is also necessary to take electron–electron collisions into account since a stationary microwave discharge is characterized by a density N_e which exceeds the critical densities by one or two orders of magnitude; it is also of highly nonequilibrium character.[4] It is therefore of interest to examine the kinetics of processes occurring in a microwave discharge, taking account of the electromagnetic field and electron–electron, elastic, and inelastic collisions. The foregoing processes are taken into account in refs. 7 and 8 in the positive column of a dc discharge.

The present study is an attempt at a theoretical and experimental investigation of processes in a low-temperature microwave discharge using as an example the excitation of a discharge in argon by a 3-cm source.

KINETIC EQUATION

The kinetic equation for the isotropic part of the electron velocity distribution function $f_0(v)$ in a low-temperature plasma excited by a rapidly alternating field of frequency ω can be written in the form

$$\frac{1}{2v^2}\frac{\partial}{\partial v}\left\{v^2 P(v)\frac{\partial f_0}{\partial v}+v^3 P_1(v) f_0\right\}=(h_x+h_i)\nu_c f_0, \tag{1}$$

where

$$P_1(v)=2A_1(f_{00})+\delta\nu_m, \tag{2}$$

$$P(v)=2A_2(f_{00})+\frac{e^2E^2}{3m^2}\frac{\nu_m}{\nu_m^2+\omega^2}+\frac{kT_g}{m}\delta\nu_m. \tag{3}$$

Here, $A_1(f_{00})$ and $A_2(f_{00})$ describe the electron–electron interaction,[7,9] with the distribution function replaced by its first iteration, i.e., by the Maxwellian distribution; ν_m is the frequency of momentum-transfer elastic collisions; ν_c is the total collision frequency; h_x and h_i are the excitation and ionization efficiencies, respectively; T_g is the gas temperature; E is the electric field in the plasma. The remaining notation is standard. The electron–electron collisions depend on the electron density N_e and the temperature T_{1e} in the first iteration. To find these parameters in the general case it is necessary to solve the ionization and energy balance equations[9] for the function $f_0(v)$ defined by Eq. (1).

Following Kagan and Lyagushchenko,[7] we disregard the interaction with excited atoms, assuming their density to be small. Neglect of diffusion also imposes a lower bound on the permissible pressure values.[7,10]

There are no exact methods for solving Eq. (1). The inelastic collisions are usually taken into account with the aid of asymptotic methods.[5-7] In the case of the positive column of a dc discharge the WKB asymptotic form of the distribution function has been investigated in detail in refs. 7 and 8. The asymptotic distribution function used in these papers imposes a limitation on the electric-field amplitude. This limitation is dictated by the approximate method of determining the turning point, a knowledge of which is essential for an asymptotic representation of the distribution function in the inelastic interaction region.

In a dc discharge this limitation is of little importance in most cases; however, a microwave discharge is characterized by much higher values of the electric field.[11] We therefore propose in the present paper an asymptotic representation of the distribution function, such that the turning point coincides with the excitation threshold. We solve the kinetic equation in the following manner. We represent f_0 in the form

$$f_0=\varphi\Phi, \tag{4}$$

where

$$\varphi(v)=\exp\left\{-\int_0^v\frac{P_1(v)}{P_1(v)}v\,dv\right\}\equiv e^{-F(v)} \tag{5}$$

is the integral of Eq. (1) with zero right-hand side. By substituting (4) in (1) we obtain the following equation for Φ:

$$\frac{d^2\Phi}{d\xi^2}-Q(\xi)\Phi=0, \tag{6}$$

where $Q(\xi) = 2v^2(\xi)\varphi(\xi)h(\xi)\nu_c(\xi)q(\xi)$; $h = h_x + h_i$, and the new independent variable is defined by the relation

$$d\xi=\frac{dv}{v^2\varphi(v)P(v)}\equiv\frac{dv}{q(v)}. \tag{7}$$

It is easy to verify that replacement of the function to be found transforms the kinetic equation to the self-conjugate form; replacement of the independent variable (7) leads to the second canonical form, an equation of the wave type. Since $h(v) \equiv 0$ when $v < v_x$, where v_x corresponds to the excitation threshold, the quantity Q vanishes at all finite values $v \geq v_x$ only at the point ξ_x corresponding to $v = v_x$. It is known from the experimental data that $h\nu_c \sim v - v_x$ near threshold, so that the asymptotic form of the solution of (6) takes the following form:

$$\begin{aligned} \Phi &= C_1 + C_2 \int_0^v \frac{e^{F(v)}}{v^2 P(v)}\, dv \quad \text{if } v \leqslant v_x, \\ \Phi &= A \left[\frac{L}{Q^{1/2}}\right]^{1/2} K_{1/3}(L) \quad \text{if } v \geqslant v_x. \end{aligned} \tag{8}$$

Here,

$$L = \int_{v_x}^{v} \sqrt{\frac{2h\nu_e}{P(v)}}\, dv;$$

$K_{1/3}(L)$ is the MacDonald function. The integration constants C_1 and C_2 can be expressed in terms of the constant A by using the continuity conditions for the distribution function and its derivatives at the point $v = v_x$.

If we choose the independent variable to be the energy $u = mv^2/2$, we can obtain the electron energy distribution function $g_0(u)u^{1/2}$:

$$g_0(u)\, u^{1/2} = \begin{cases} A u^{1/2} e^{-F(u)} \left[1 - \frac{B}{2u_x} \int_u^{u_x} \left(\frac{u_x}{u}\right)^{3/2} \frac{P(u_x)}{P(u)} e^{F(u) - F(u_x)} du \right] & \text{if } u \leqslant u_x, \\ A u_x^{\frac{1}{2}} e^{-\frac{1}{2}[F(u) + F(u_x)]} \dfrac{\left(\frac{L}{Q^{1/2}}\right)^{1/2} K_{1/3}(L)}{\left[\left(\frac{L}{Q^{1/2}}\right)^{1/2} K_{1/3}(L)\right]_{u=u_x}} & \text{if } u \geqslant u_x. \end{cases} \tag{9}$$

The constant B is defined by the expression

$$B = u_x \frac{P_1(u_x)}{P(u_x)} - 1 + 2u_x \left\{\frac{\partial}{\partial u} \ln \left[\left(\frac{L}{Q^{1/2}}\right)^{1/2} K_{1/3}(L)\right]\right\}_{u=u_x},$$

and the quantity A is determined from the normalization condition

$$N_e = \int_0^\infty g_0(u)\, u^{1/2} du.$$

ENERGY BALANCE EQUATION AND FIELD IN PLASMA

As noted above, the density N_e and the temperature T_{1e}, which enter in the expression (9) for the distribution function, should be determined in the general case by simultaneously solving the ionization and energy balance equations. Under conditions typical of a nonequilibrium microwave discharge, the ionization and recombination processes proceed in many steps and are closely related to the kinetics of population of the atoms over the excited states.[12] On the other hand, the simultaneous determination of the electron energy distributions in the free and bound states is a very complicated problem; thus, instead of solving the ionization balance equation we use here the experimental values of N_e and determine the remaining unknown parameter T_{1e} from the energy balance equation.

In the energy balance equation we take account of the energy acquired by the electron from the electromagnetic field and the energy lost in elastic and inelastic collisions. The inelastic losses are due mainly to transitions to the first excited level.[12] The influence of collisions of the second kind will be neglected. The energy lost in direct ionization, according to our estimates, turns out to be negligibly small, while the losses due to stepwise ionization from the first excited state are of the order of several per cent of the total loss, and are therefore also disregarded here.

The energy balance equation is

$$\delta \int_0^\infty \nu_m u^{1/2} (u - u_g) g_0(u)\, du + \int_{u_x}^\infty h_x \nu_e u^{3/2} g_0(u)\, du = \int_0^\infty g_0(u) \frac{\partial}{\partial u} (\nu_{eE} u^{3/2})\, du. \tag{10}$$

We have used the notation

$$\nu_{eE} = 8.79 \cdot 10^{14} \frac{E^2}{u_{1e}\omega^2} \frac{\nu_m}{1 + \frac{\nu_m^2}{\omega^2}}, \tag{11}$$

$u_{1e} = 3kT_{1e}/2$, $u_g = 3kT_g/2$ (eV), and E is in V/cm.

In the case of argon we approximate the excitation cross section by Fabrikant's equation, which is given in ref. 13:

$$h_x \nu_e = 4 \cdot 10^8 p_0 u^{1/2} (u - 11.6) \exp\left\{1 - \frac{u - 11.6}{2.1}\right\}. \tag{12}$$

Here p_0 is the reduced gas pressure (in mm Hg).

Equation (10) and expression (9) for the distribution function contain the field in the plasma E. Strictly speaking, this field should be obtained by solving Maxwell's equations jointly with the equation for the distribution function. This is a very complicated independent problem, and we therefore consider in the present paper the behavior of the plasma parameters in a layer with dimensions smaller than those of the skin depth. The field in the plasma will be calculated from the equation for the case in which a plane wave of amplitude E_0 is incident on a half-space with homogeneous complex dielectric con- ε (ref. 14):

$$E = \frac{2E_0}{1 + \sqrt{\varepsilon}}, \tag{13}$$

where ε is determined by the relation

$$\varepsilon = 1 - \frac{4\pi e^2 N_e}{m(\omega^2 + \nu_{\text{eff}}^2)} \left\{K_e + i \frac{\nu_{\text{eff}}}{\omega} K_e\right\}. \tag{14}$$

Here, ν_{eff} is the effective frequency of the collision of the electrons with the neutrals, calculated for the first iteration of the distribution function.

RESULTS OF NUMERICAL CALCULATION AND COMPARISON WITH EXPERIMENT

The solution of the balance equation (10) and the de-

TABLE 1

	6	14.5	20	80
p_0 (mm Hg)	3.6	8.34	11.5	41
E (V/cm)	69.4	47.3	43	41.7
T_{1e}(eV)	1.42	1.276	1.24	1.182
Λ (cm)	0.09	0.061	0.056	0.059

termination of the distribution function (9) have been carried out with a computer for the values $E_0 = 200$ V/cm and $\omega = 5.88 \cdot 10^{10}$ sec^{-1} in the pressure range 6-80 mm Hg. The electron densities N_e needed for the calculation are determined experimentally by microwave measurements of the plasma, using an arrangement described in detail in ref. 15; the dependence of the gas temperature T_g on the pressure is estimated with the aid of a tungsten thermocouple. The microwave discharge is ignited in a quartz tube with inner diameter 3 mm, placed perpendicularly to the broad walls of a standard 3-cm band waveguide. The power generated by the magnetron ensures a field $E_0 \sim 200$ V/cm in the waveguide. Table 1 lists the dependence of the reduced pressure p_0, of the field E in the plasma, of the temperature T_{1e} of the first iteration of the distribution function, and of the depth Λ of the skin layer on the manometer pressure p.

The ratio of the calculated distribution function to the Maxwellian function at the same values of the electron density and temperature is shown for different pressures in Fig. 1. As expected, in the energy region beyond the excitation threshold (marked by the arrow in Fig. 1), the calculated distribution function differs markedly from a Maxwellian.1) The decrease of the high-energy part of the distribution function in comparison with the Maxwellian function, as in the case of a dc discharge,[7,8] is due to the inelastic collisions. It is of interest to note that at high energies the variation of the distribution function as a function of the electron temperature and density is much stronger than that of the Maxwellian function corresponding to the same parameters. Thus, for example, in the region $u \sim 14$ eV, when T_{1e} changes from 1.2 to 1.43 eV (p changes from 80 to 6 mm Hg), the distribution function (9) increases by three orders of magnitude. For a Maxwellian distribution function, this increase amounts to only one order of magnitude.

The losses to elastic and inelastic collisions for the considered microwave discharge are illustrated in Fig. 2, which shows the relative fractions of energy lost by the electrons to excitation, Δ_x, and to heating of the gas, Δ_y. The figure shows for comparison the distribution of the losses in a dc discharge as taken from ref. 16. The effective field for the microwave discharge is defined in the usual manner

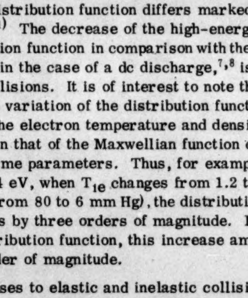

Fig. 1. Ratio of the obtained distribution function to the Maxwellian function vs the energy at different values of the reduced pressure. p_0, mm Hg: 1) 41; 2) 11.5; 3) 8.34; 4) 3.6.

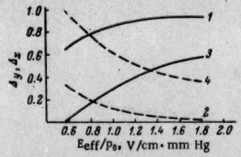

Fig. 2. Distribution of electron losses as a function of E_{eff}/p_0. 1, 2) Δ_x and Δ_y according to our calculations; 3, 4) Δ_x and Δ_y according to the data of ref. 16.

$$E_{\text{eff}} = \frac{E}{\sqrt{2}}\left(1 + \frac{\omega^2}{\nu_{\text{eff}}^2}\right)^{-1/2}.$$

The excess of inelastic losses over the elastic losses points to a less effective heating of the gas by the microwave field than in a dc discharge.

The calculated values of the electron temperature $T_e = (2/3)\langle u_e \rangle$, where $\langle u_e \rangle$ is the average energy, are shown in Fig. 3 as functions of the manometer pressure. The same figure shows the dependences of the electron density and of the electron gas, obtained experimentally and used in the calculations. The points show the experimental values of the electron temperature T_e as recalculated from the effective collision frequency measured by the microwave method. As follows from Fig. 3, the values $T_e \sim 1$-2 eV greatly exceed the value of T_g, which does not exceed 0.04-0.05 eV.

The right-hand side of Eq. (10) is the power W absorbed per unit volume in the skin layer of the microwave-discharge plasma. The absorbed power averaged over the cross section of the discharge tube is determined by experiment. For a qualitative comparison with experiment we define the averaged value of W as follows:

$$\tilde{W} = \frac{S}{S_0} W,$$

where S is the area of a ring of thickness equal to half the skin-layer depth, and S_0 is the area of the tube cross section.

Curves of W and $\tilde{W}$ versus the pressure are shown in Fig. 4. The points in this figure show the values of the specific absorbed power measured by a calorimetric method.

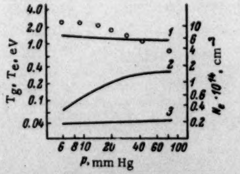

Fig. 3. Calculated dependence of the electron temperature T_e (curve 1) and experimental dependences of the electron density N_e (curve 2), of the gas temperature T_g (curve 3), and of the electron temperature T_e (points) on the pressure.

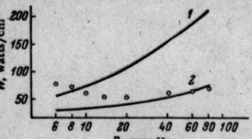

Fig. 4. Dependence of the power absorbed per cm³ of plasma on the manometer pressure. 1) W; 2) $\widetilde{W}$; the points show experimental values.

We call attention to the fact that at low pressures the experimental values of both the specific absorbed power (Fig. 4) and of the electron temperature (3) are higher than the corresponding calculated values. This discrepancy can apparently not be attributed to purely collisional absorption.[17-19]

At high pressures, the discrepancy in the experimental data in Fig. 4 is probably due to failure to take into account the spatial redistribution of the field inside the discharge gap and to neglect of the inhomogeneity of the electron density over its cross section.

CONCLUSIONS

1. By solving the Boltzmann kinetic equation including the electromagnetic field, the electron–electron, elastic, and inelastic collisions, we have obtained the electron energy distribution function in a microwave discharge; this distribution differs substantially from the Maxwellian distribution in the inelastic-interaction region.

2. A numerical solution has been obtained for the energy balance equation, using the obtained distribution function, and graphs have been constructed for the theoretical dependences of the electron temperature, of the elastic and inelastic losses, and of the power absorbed per unit plasma volume on the pressure.

3. The method discussed in the present paper makes it possible to determine by calculation important parameters of the plasma of a microwave discharge from known values of the electron density and the gas pressure.

The authors thank F. G. Bass and Yu. G. Gurevich for a discussion of the results and for useful remarks.

Electron energy distribution and electrical characteristics of the positive column in H_2 and $H_2 + Cl_2$

V. V. Zaitsev, A. I. Maksimov, and V. I. Svettsov
Ivanov Chemical Engineering Institute

(Submitted March 26, 1973; resubmitted May 28, 1973)
Zh. Tekh. Fiz., 44, 98-101 (January 1974)

The spatial variation of the electron energy distribution, the plasma potential, and of the floating potential in a striated glow discharge in hydrogen and in a hydrogen–chlorine mixture is studied experimentally at a pressure of 0.258 mm Hg and a current of 15 mA in a tube 26 mm in diameter and 50 cm long. It is shown that the fraction of high-energy electrons in the distribution function increases at a chlorine concentration of 0.01-0.1%. The radial variation of the floating potential and the plasma potential points to the possible existence of negative ions in the presence of chlorine.

The speed of processes in low-pressure discharge plasmas is in large measure determined by collisions of fast electrons. Thus, kinetic calculations require a knowledge of the electron energy distribution over the entire discharge volume. The distribution function has been investigated by many authors in inert[1–5] and molecular[6–9] gases.

It has been shown[10–12] that the degree of certain diatomic gases in a low-pressure discharge increases in the presence of small amounts of impurities which, as a rule, have a higher electron capture cross section; this leads to the production of negative ions. It seems that one mechanism by which impurities affect the plasma is the deformation of the electron energy distribution function, which changes the rate of dissociation of molecules under the action of electron impacts. In the present work we study the effect of chlorine impurities on the electron energy distribution in a striated positive column in a glow discharge in hydrogen. The investigations pertain to a discharge tube 26 mm in diameter and 500 mm long, at a current of 15 mA, and a pressure of 0.26 mm Hg. The linear gas flow velocity through the tube is several centimeters per second. The hydrogen is purified with the aid of a titanium generator[13] and is dried by cooling to liquid-nitrogen temperature. The chlorine is produced by thermal decomposition[14] of $CuCl_2$.

The electron energy distribution has been plotted by the method proposed by M. Druyvesteyn[15] using the experimental arrangement described in refs. 16 and 17. The plasma potential is found by equating to zero the second derivative of the probe current.[18–20]

The measurements are performed with 0.08-cm platinum probes with uninsulated tips 3 mm long which can be moved along the discharge tube axis and radius. The axial and radial positions of the probes can be measured to within ± 0.5 mm and ± 0.05 mm, respectively.

Before the measurements the discharge tube is processed for 3-4 h in pure hydrogen and then evacuated to a pressure of 10^{-5} mm Hg. To clean the probe a current five to six times the normal operating current (i.e., 250-300 mA) is drawn through the probe during processing.

The distribution function is normalized to unity using the expression

$$\int_0^\infty \sqrt{u}\,\frac{d^2i}{du^2}\,du = 1, \tag{1}$$

where u is the probe potential with respect to plasma.

The electron density is calculated from the probe current i_g and plasma potential

$$n_e = \frac{i_g}{e}\,\frac{4}{S}\,\frac{1}{\sqrt{\frac{2e}{m}}}\,\frac{\int_0^\infty \sqrt{u}\,\frac{d^2i}{du^2}\,du}{\int_0^\infty u\,\frac{d^2i}{du^2}\,du}. \tag{2}$$

Here, S is the probe area, and e and m are the electron charge and mass, respectively. Numerical calculations with expressions (1) and (2) have been carried out on a Promin'-2 computer.

RESULTS

We have investigated the effect of chlorine concentration in hydrogen on the electron energy distribution function. Typical results are shown in Figs. 1-3. In all measurements the distribution function has, in addition to the main peak at about 1 eV, a second peak at 10-15 eV.

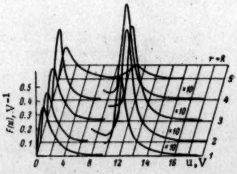

Fig. 1. Radial variation of electron energy distribution function in the positive column of a glow discharge. x/L = 0.1, where x is the distance from the cathode end of the striation, and L is the length of the striation. r: 1) 0; 2) 2; 3) 5; 4) 8; 5) 11.

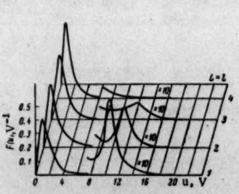

Fig. 2. Variation of electron energy distribution function for different locations of probe in a striation. *l*: 1) 0; 2) 4; 3) 8; 4) 11.

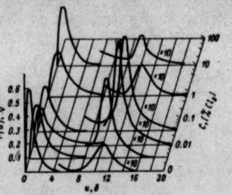

Fig. 3. Effect of electronegative impurity on the distribution function for r/R = 0.1 and x/L = 0.1.

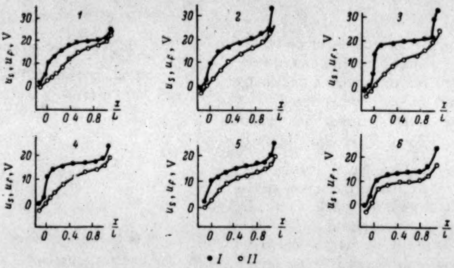

Fig. 4. Longitudinal variation of potential. 1) Plasma potential, u_s; II) floating potential, u_f; 1) H_2; Cl_2: 2) 0.004%; 3) 0.01%; 4) 0.04%; 5) 0.7%; 6) 10%.

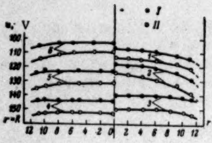

Fig. 5. Radial variation of potential. I) Plasma potential, u_s; II) floating potential, u_f; 1) H_2; Cl_2: 2) 0.004%; 3) 0.01%; 4) 0.04%; 5) 0.07%; 6) 10%.

In the direction from the axis towards the tube walls, the distribution function is enhanced by fast electrons from the second peak (Fig. 1, H_2 + 0.04% Cl_2) (see ref. 21). Along any given striation the peak decreases in the direction towards the discharge tail. The second peak disappears entirely in the tail of a striation (Fig. 2, H_2 + 0.04% Cl_2).

The data in Fig. 3 indicate that the addition of chlorine has a marked effect on the distribution function even at energies beyond the dissociation threshold of hydrogen molecules. This mechanism should thus appreciably affect the rate of dissociation of hydrogen molecules under the action of electron impacts and also the yield of hydrogen atoms.

The available data are insufficient for a detailed interpretation of the changes in the distribution function. Clearly, chlorine molecules, which cause rapid volume annihilation of electrons in the course of dissociative capture, change the charge balance conditions and the conditions of striation formation. The axial variation of the potential with impurity content is not gradual. The most rapid potential change at the beginning of a striation is observed at about 0.01% Cl_2 (Fig. 4). The variations of the longitudinal field and the electron energy distribution function are obviously closely related.

At the same time, the electron capture cross section and the ionization potential of Cl_2[22] have maxima near the first and second peaks respectively of the distribution function. It is thus reasonable to expect that the process of electron capture should reduce the first group in the distribution function, while the quite strong ionization of Cl_2 in high chlorine concentrations attenuates the second peak. Our measurements prove that the rate of electron capture is quite high at a chlorine concentration of about 0.01%. Figure 5 shows the radial distribution of potential for different Cl_2 concentrations. At about 0.01% Cl_2, the radial distribution is practically flat, indicating a high relative density of negative ions.[23]

Effect of electron–atom collisions on electron motion in a gas diode

V. I. Babanin and A. Ya. Énder

Ioffe Physicotechnical Institute,
Academy of Sciences of the USSR, Moscow

(Submitted April 9, 1973)
Zh. Tekh. Fiz., 44, 102-112 (January 1974)

The kinetic equation for the electron distribution function in the gap of a plane gas diode is solved with elastic scattering of electrons by atoms. Specific calculations are made under the following assumptions: 1) The electric field is constant over the gap; 2) the scattering cross section is inversely proportional to electron velocity. The electron density and flux are computed in addition to the distribution function. The effect of various boundary conditions at the cathode on the parameters in question is considered. At low Knudsen numbers the diffusion approximation is valid and Knudsen-layer effects are demonstrated near the boundary. Study of the current as a function of the initial electron velocity at the cathode shows that the reflection onto the cathode is strongest when the initial electron energy is of the order of the energy acquired in the electric field in crossing the gap. For thermionic emission from the cathode a good approximate boundary condition is provided by an isotropic monoenergetic distribution with a velocity modulus that is equal to the mean-square velocity of the initial Maxwellian distribution.

The behavior of electrons in the gap of a gas diode is determined by the nature of the electric field and by collision processes. At modest voltages, for which excitation and ionization processes can be neglected, it is necessary to take account of elastic scattering of electrons by atoms. Reference 1 gives numerical estimates for the effect of electron scattering on the volt–ampere characteristic and the potential distribution over the diode gap for Knudsen numbers on the order of unity, using the Monte Carlo method. Reference 2 uses a kinetic equation to investigate the effect of electron scattering on the current passing through the diode when there is a plasma in the gap and the potential jumps are concentrated in narrow regions near the electrodes. In this case no electric field is present in the basic part of the gap in which scattering occurs.

In the present paper we solve the kinetic equation for the electron distribution function in the diode with an electric field in the gap, over a wide range of Knudsen numbers. The solution of the kinetic problem is necessary to compute the volt–ampere characteristics of the diode. In addition, a knowledge of the electron distribution function near the anode is needed to compute the ignition potential in the diode. In the region of low Knudsen numbers we consider the transition to the diffusion approximation and compare the results obtained in this approximation with the exact solutions. This procedure makes it possible to evaluate the effect of Knudsen boundary layers on the diode characteristics.

Consider a plane horizontal diode with transverse electrode dimensions that greatly exceed the electrode spacing d. We direct the x axis from the cathode to the anode and take the cathode to be the origin of the x coordinate and the potential $\Phi(x)$. The electron distribution function $f(x, \mathbf{v})$ depends on x and the velocity $\mathbf{v}$ with its components v_x, v_y, v_z. Since energy transfer in elastic collisions between electrons and atoms is small (of the order of the electron–atom mass ratio), we can neglect energy losses in collision events. In this approximation a collision only affects the direction of the electron velocity, and the kinetic equation can be written in the form

$$v_x \frac{\partial f(x, \mathbf{v})}{\partial x} + \frac{e}{m} \frac{d\Phi(x)}{dx} \frac{\partial f(x, \mathbf{v})}{\partial v_x} = \frac{f^*(x, v) - f(x, \mathbf{v})}{\tau(v)},$$

$$f^*(x, v) = \frac{1}{4\pi} \int\limits_{(4\pi)} f(x, \mathbf{v})\, d\Omega. \qquad (1)$$

Here, we use the model of the collision integral in which the term describing the approach to a given point of phase volume is proportional to the velocity of the distribution function as averaged over direction. In (1), e is the charge and m is the mass of the electron, $\tau(v) = [n_a \Sigma(v) v]^{-1}$ is the time between collisions, n_a is the density of atoms, and $\Sigma(v)$ is the total scattering cross section, which depends on the modulus of v. If the differential cross section is independent of the scattering angle, Eq. (1) is exact. The boundary conditions at the electrodes are

$$f(0, \mathbf{v})|_{v_x>0} = f_0(\mathbf{v}); \quad f(d, \mathbf{v})|_{v_x<0} = f_d(\mathbf{v}). \qquad (2)$$

Equation (1) with boundary conditions (2) can be formally integrated (see, e.g., ref. 3, where a similar procedure is carried out for a kinetic equation describing ion motion allowing for resonant charge transfer on atoms). If we limit ourselves to a monotonic potential distribution ($d\Phi/dx > 0$), after integration[1)] we have

$$f(x, \mathbf{v}) = \begin{cases} f_0[u(0), v_y, v_z]\, Z(0, x) + \int\limits_0^x J Z(x', x) \frac{dx'}{u(x')}; \\ \qquad \sqrt{\frac{2e\Phi(x)}{m}} < v_x < v, \\ \int\limits_\eta^x J Z(x', x) \frac{dx'}{u(x')} + \Bigl[f_d[-u(d), v_y, v_z]\, Z(\eta, d) \\ \quad + \int\limits_\eta^d J Z(\eta, x') \frac{dx'}{u(x')} \Bigr] Z(\eta, x); \quad 0 < v_x < \sqrt{\frac{2e\Phi(x)}{m}}, \\ f_d[-u(d), v_y, v_z]\, Z(x, d) + \int\limits_x^d J Z(x, x') \frac{dx'}{u(x')}; \\ \qquad -v < v_x < 0, \end{cases} \qquad (3)$$

$$J \equiv J[x', v(x')] = \tau^{-1}[v(x')]\, f^*[x', v(x')], \qquad (4)$$

$$Z(x_1, x_2) = \exp\left\{ -\int\limits_{x_1}^{x_2} \frac{dx''}{\tau[v(x'')]\, u(x'')} \right\}. \qquad (5)$$

Here,

$$u(x') = |v_x'| = \sqrt{v_x^2 - \frac{2e}{m}[\Phi(x) - \Phi(x')]}$$

is the absolute value of the x component of the velocity, and

$$v(x')=\sqrt{u(x)^2+v_y^2+v_z^2}$$

is the modulus of the electron velocity at x if at x the corresponding values are $|v_x|$ and v and the electron traverses a path between x' and x without collisions. Expressions (4) and (5) have a simple physical meaning: $jdx'dv'_x$ yields the electron flux resulting from collisions in an element of phase space $dx'dv'_x$ (the remaining coordinates being omitted as inessential). The fraction Z(x, x') of this flux [or Z(x,x'), depending on the direction of motion] reaches the point x and makes a contribution

$$JZ(x',\ x)\frac{dx'}{u(x')}$$

to the distribution function. Thus, the integral terms in (3) are the contributions to the distribution function from electrons that have experienced collisions in the gap prior to arriving at point x. The terms outside the integrand describe particles that have arrived at the point in question from the electrodes without collisions. In writing *f*(x, v) in the interval

$$0<v_x<\sqrt{\frac{2e\Phi(x)}{m}}$$

we allow for two possible types of electron trajectories: The first term corresponds to particles that move between the points x' and x (x' < x) with velocity projection $v'_x > 0$, while the second corresponds to particles on reverse trajectories, i.e., those which move from x' (x' > x) to the return point η with $v'_x < 0$ and then from η to x with $v'_x > 0$. The point η is determined from the condition $u(\eta) = 0$.

If we neglect energy losses in collisions, the total electron energy is conserved:

$$W=\frac{mv^2}{2}-e\Phi(x)=\text{const.}$$

Consequently, contributions to the distribution function at x for the given value of the modulus of v, i.e., the total energy W, can only come from those electrons which have the same total energy at other points. In other words, electrons with different total energies move independently of one another in the gap. If, therefore, we change from v to W in (3)-(5), i.e., if we assume that

$$v\equiv v(x,\ W)=\sqrt{\frac{2}{m}[W+e\Phi(x)]}, \qquad (7)$$

and introduce the distribution function

$$f(x,\ W,\ \vartheta,\ \varphi)=f[x,\ v(x,\ W),\ \vartheta,\ \varphi]\frac{v(x,\ W)}{m}$$

with respect to the energy W and angles ϑ and φ of a spherical coordinate system whose polar axis is directed along x, the variable W becomes a parameter of the equation. The equation itself describes the motion in the gap of electrons emitted by the cathode with kinetic energy W and by the anode with corresponding energy $W + e\Phi_d$ (Φ_d being the anode potential). Integrating both parts of the equation for *f*(x, W, ϑ, φ) over the angles and changing the order of integration on the right side, we can obtain an integral equation for the distribution function

$$\varphi(x,\ W)=4\pi f^*[x,\ v(x,\ W)]\frac{v(x,\ W)}{m}$$

over the energy W:

$$\varphi(x,\ W)=\varphi_0(x,\ W)\theta(W)+\varphi_d(x,\ W)\theta[W+e\Phi(x)] + \int\limits_{\eta(W)\theta(-W)}^{d} K(x,\ x',\ W)\varphi(x',\ W)\,dx'. \qquad (8)$$

Here, η(W) is determined from the condition

$$v(\eta,\ W)=0,\quad \theta(x)=\begin{cases}1, & x>0,\\ 0, & x<0,\end{cases}$$

$$K(x,\ x',\ W)=\frac{v(x',\ W)^{-1}}{2\tau(x',\ W)} \times \begin{cases} \displaystyle\int\limits_{\sqrt{\frac{2e}{m}[\Phi(x)-\Phi(x')]}}^{v(x,\ W)} Z(x',\ x)\frac{dv_x}{u(x')} + \int\limits_{\sqrt{\frac{2e}{m}[\Phi(x)-\Phi(x')]}}^{\sqrt{\frac{2e}{m}\Phi(x)}} Z(\eta,\ x')Z(\eta,\ x)\frac{dv_x}{u(x')}, & x'<x,\\ \displaystyle\int\limits_{-v(x,\ W)}^{0} Z(x,\ x')\frac{dv_x}{u(x')} + \int\limits_{0}^{\sqrt{\frac{2e}{m}\Phi(x)}} \cdot Z(\eta,\ x')Z(\eta,\ x)\frac{dv_x}{u(x')}; & x'>x,\end{cases} \qquad (9)$$

$$\left.\begin{aligned} \varphi_0(x,\ W)&=\frac{1}{m}\int\limits_0^{2\pi} d\varphi \int\limits_{\sqrt{\frac{2e}{m}\Phi(x)}}^{v(x,\ W)} f_0\Bigg[\sqrt{\frac{2W}{m}},\\ &\qquad \arccos\left[\frac{u(0)}{v(0,\ W)}\right],\ \varphi\Bigg] Z(0,\ x)\,dv_x,\\ \varphi_d(x,\ W)&=\frac{1}{m}\int\limits_0^{2\pi} d\varphi\Bigg\{\int\limits_{-v(x,\ W)}^{0} f_d\Bigg[\sqrt{\frac{2(W+e\Phi_d)}{m}},\\ &\qquad \arccos\left(\frac{-u(d)}{v(d,\ W)}\right),\ \varphi\Bigg] Z(x,\ d)\,dv_x\\ &\qquad + \int\limits_0^{\min\left[v(x,\ W),\ \sqrt{\frac{2e}{m}\Phi(x)}\right]} f_d\Bigg[\sqrt{\frac{2(W+e\Phi_d)}{m}},\\ &\qquad \arccos\left(\frac{-u(d)}{v(d,\ W)}\right),\ \varphi\Bigg] Z(\eta,\ d)Z(\eta,\ x)\,dv_x\Bigg\}. \end{aligned}\right\} \qquad (10)$$

In (9)-(10), $\tau(x,\ W) \equiv \tau[v(x,\ W)]$ and $Z(x_1,\ x_2)$ is determined from Eq. (5) with $\tau[v(x'')]$ replaced by $\tau(x'',\ W)$. The equations in (10) contain boundary functions (2) in the spherical coordinate system. Once $\varphi(x,\ W)$ is known we can readily compute the distribution function *f*(x, W, ϑ, φ) and the current density F(x, W) of electrons with a given energy W. The latter is determined by the right side of (8) with dv_x in (9) and (10) replaced by $v_x dv_x$. The total density n and flux ν at x are obtained by integrating $\varphi(x, W)$ and $F(x, W)$ with respect to the energy W.

We limit ourselves to the case in which the anode does not emit electrons and in which electrons which reach the electrodes are completely absorbed. In this case $f_d(v) = 0$, and $f_0(v)$ characterizes an external source at the cathode.[2] The boundary conditions on the cathode that we consider will be of three different types: a) a beam with fixed velocity v_0 directed along the normal to the cathode; b) an isotropic distribution with velocity modulus v_0; and c) a Maxwellian distribution with cathode temperature T.

The boundary functions $f_0(v)$ for $v_x > 0$, as normalized to the flux ν_0 in the x direction, have the following form, respectively:

$$\text{a)}\quad f_0=\frac{\nu_0}{2\pi v_0^3}\delta(v-v_0)\,\delta(1-\cos\vartheta),$$

$$\text{b)}\quad f_0=\frac{\nu_0}{\pi v_0^3}\delta(v-v_0),$$

$$\text{c)}\quad f_0=\frac{2\alpha^2\nu_0}{\pi}\exp(-\alpha v^2),\quad \alpha=\frac{m}{2kT}.$$

In cases a and b, the total energy $W_0 = (mv_0^2)/2$ is fixed and $\varphi_0(x, W)$ [and consequently, $\varphi(x, W)$ as well] is proportional to $\delta(W - W_0)$. Setting $\varphi_d = 0$ in (8) and integrating with respect to W, we obtain the following equation for $n(x, W_0)$, the density of monoenergetic electrons emitted by the cathode:

$$n(x,\ W_0)=n_0(x,\ W_0)+\int\limits_0^d K(x,\ x',\ W_0)\,n(x',\ W_0)\,dx'. \tag{11}$$

Here, $n_0(x, W_0)$ is the coefficient for $\delta(W - W_0)$ in (10) for $\varphi_0(x, W)$. Expressions for the distribution function $\chi(x, W_0, \vartheta, \varphi)$ over the angles and flux $\nu(x, W_0)$ of monoenergetic electrons in terms of $n(x, W_0)$ can be obtained similarly from the expressions for $f(x, W, \vartheta, \varphi)$ and $F(x, W)$. The solution of the problem for boundary condition c is found as the superposition of the solutions obtained for case b with various v_0 values, each solution being taken with weight $W_0/(kT)^2 \exp(-W_0/kT)$. For example, the density is

$$n(x)=\int\limits_0^\infty \frac{W_0}{(kT)^2}\exp\left(-\frac{W_0}{kT}\right)n(x,\ W_0)\,dW_0. \tag{12}$$

We use the resultant equations to calculate the boundary conditions of the form a, b, and c with the following assumptions: 1) τ = const, i.e., $\sum \sim 1/v$, and 2) the electric field E = const. These assumptions make the problem more specific and result in simplifications in the kernel of integral equation (8). The first assumption holds approximately for helium atoms;[4] the second holds at low current densities, where space-charge effects are unimportant. This assumption can also be used in analyzing deviations from the 3/2 law associated with scattering.

Let us consider the solution of (11) in greater detail. In changing to dimensionless variables, the basic parameter of the problem is isolated:

$$N=\frac{2d}{v_d\tau},\quad v_d=\sqrt{\frac{2e\Phi_d}{m}}=\sqrt{\frac{2e\,|E|\,d}{m}}.$$

For $e\Phi_d \gg W_0$ the parameter N is roughly equal to the inverse of the Knudsen number. (In the other limiting case, $e\Phi_d \ll W_0$, the function of the inverse Knudsen number is provided by the quantity $d/v_0\tau = v_dN/2v_0$.) In dimensionless variables (11) assumes the form

$$y(u)=y_0(u)+\int\limits_0^1 K(u,\ u')\,y(u')\,du', \tag{13}$$

$$K(u,\ u')=\frac{Nu'}{2\sqrt{u'^2+u_0^2}}\begin{cases}\displaystyle\int\limits_{\sqrt{u^2-u'^2}}^{\sqrt{u^2+u_0^2}}\exp[-N(\rho-\rho')]\frac{d\rho}{\rho'} \\ \displaystyle+\int\limits_{\sqrt{u^2-u'^2}}^{\infty}\exp[-N(\rho+\rho')]\frac{d\rho}{\rho'}, & u>u', \\ \displaystyle\int\limits_{-\sqrt{u^2+u_0^2}}^{\infty}\exp[-N(\rho'+\rho)]\frac{d\rho}{\rho'}, & u<u'.\end{cases} \tag{14}$$

Here

$$u=\sqrt{\frac{x}{d}}=\frac{\sqrt{\frac{2e}{m}\Phi(x)}}{v_d},\quad u_0=\frac{v_0}{v_d},$$

$$\rho=\frac{v_x}{v_d},\quad \rho'=\sqrt{\rho^2-(u^2-u'^2)}.$$

The density is measured in units of $n_0 = \nu_0/v_d$.

Substituting the boundary distribution functions into (10) we obtain the following for the term outside the integrand in (13):

$$y_0(u)=\begin{cases}\dfrac{1}{\sqrt{u^2+u_0^2}}\exp\left[-N\left(\sqrt{u^2+u_0^2}-u_0\right)\right] & \text{for case a)}, \\ \dfrac{2}{u_0^2}\displaystyle\int\limits_0^{u_0}\frac{\exp\left[-N\left(\sqrt{u^2+\rho_0^2}-\rho_0\right)\right]\rho_0\,d\rho_0}{\sqrt{u^2+\rho_0^2}} & \text{for case b)},\end{cases} \tag{15}$$

We also write out the expression for the dimensionless flux $i = \nu/\nu_0$:

$$i(u)=i_0(u)+\int\limits_0^1 K_1(u,\ u')\,y(u')\,du'. \tag{16}$$

Here the kernel $K_1(u, u')$ is determined from (14) with $d\rho$ replaced by $\rho\,d\rho$, and

$$i_0(u)=\begin{cases}\exp\left[-N\left(\sqrt{u^2+u_0^2}-u_0\right)\right] & \text{for case a}, \\ \dfrac{2}{u_0^2}\displaystyle\int\limits_0^{u_0}\exp\left[-N\left(\sqrt{u^2+\rho_0^2}-\rho_0\right)\right]\rho_0\,d\rho_0 & \text{for case b}.\end{cases} \tag{17}$$

When the number of collisions is large ($N \gg 1$), the expression for the flux at a distance from the boundaries can be simplified. In this case the principal term in (16) is the integral term, and the kernel has a sharp peak for $u = u'$. Expanding $y(u')$ in a Taylor series in the neighborhood of u and limiting ourselves to the first two terms in the expansion, we obtain the diffusion equation

$$i=\frac{1}{3N}y(u)-2\frac{u^2+u_0^2}{3N}\frac{dy}{d(u^2)}, \tag{18}$$

whose solution, allowing for the fact that the flux is con-

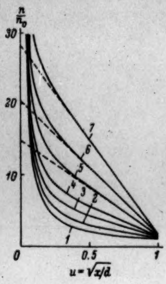

Fig. 1. Density distributions over the gap for u = 0. N: 1) 0; 2) 1; 3) 2; 4) 3; 5) 5; 6) 7; 7) 10.

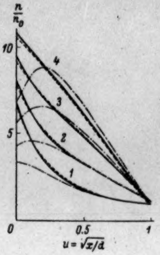

Fig. 2. Density distributions over the gap for $u_0 = u_m = 0.3$: boundary conditions a are represented by the dot–dash lines, conditions b by the dashed lines, and c by the solid lines; N: 1) 0; 2) 2; 3) 5; 4) 10.

stant over the gap, has the form $y(u) = 3Ny[1 + C(u^2 + u_0^2)^{1/2}]$, C being an arbitrary constant. This solution is a monotonic function of u, which is linear for $u_0 = 0$. We can similarly obtain the diffusion equation in the general case of an arbitrary dependence of the cross section on the energy and an arbitrary potential distribution. In dimensional variables, this has the form

$$\nu = U\,|E|\,n - D\frac{dn}{dx}. \tag{19}$$

Here

$$U = \frac{e\tau(x,\ W_0)}{3m} \text{ and } D = \frac{v^2(x,\ W_0)\,\tau(x,\ W_0)}{3}$$

are the local mobility and diffusion coefficients. Equation (19) has also been obtained in ref. 5 for a mean free path that is independent of velocity.

To obtain a numerical solution, Eq. (13) is reduced to a system of algebraic equations.[6] Assume that u_m, m = 0, 1, . . ., n, are points which break down the interval $0 \leq u \leq 1$ into n equal parts. Then the system of equations for determining the approximate values of the density y_m at the points $\tilde{u}_m = (u_{m-1} + u_m)/2$ has the form

$$\begin{gathered} y_m = y_{0m} + \sum_{p=1}^{n} A_{mp} y_p; \\ A_{mp} = \int\limits_{u_{p-1}}^{u_p} K(\tilde{u}_m,\ u')\,du';\quad m = 1,\ 2,\ \ldots\ n. \end{gathered} \tag{20}$$

The matrix elements A_{mp} are double integrals over fairly complex regions in the u', ρ plane, the integrand having a singularity at u' = u, ρ = 0 in the diagonal elements. After making the change of variables $t = N(\rho \pm \rho')$, $z = N\rho$ (the sign of ρ' being the same as the corresponding sign in the argument of the exponent of the integrand), we can integrate analytically with respect to the variable z; as a result we obtain

$$A_{mp} = I_{m,\,p-1} - I_{mp} + J_{mp} + \begin{cases} E_{mp} - E_{m,\,p-1}; & p < m, \\ 2 - E_{m,\,p-1} - E_{mp}; & p = m, \\ E_{m,\,p-1} - E_{m,\,p}; & p > m. \end{cases} \tag{21}$$

Here

$$E_{mp} = \exp(-|a_{mp}|),\ \ I_{mp} = a_{mp}[Ei(-|a_{mp}|) - Ei(-b_{mp})];$$
$$a_{mp} = N\left(\sqrt{\tilde{u}_m^2 + u_0^2} - \sqrt{u_p^2 + u_0^2}\right),\ \ b_{mp} = N(\tilde{u}_m + u_p);$$

Ei(x) is an integral exponent;

$$J_{mp} = N\int\limits_{u_{p-1}}^{u_p} \frac{(t - \tilde{u}_m)\exp[-N(t + \tilde{u}_m)]}{\sqrt{t^2 + u_0^2} + \sqrt{\tilde{u}_m^2 + u_0^2}}\,dt.$$

After computing the matrix elements, Eq. (20) is solved by successive approximations. We investigate the accuracy of the computations by varying the number of segments n and by checking the constancy of the flux at various points of the gap. The final data are obtained for n = 20. The error in the results for N = 10 and $u_0 \ll 1$ does not exceed 5% and decreases rapidly with decreasing number of collisions.

Let us now consider the computational results. Figures 1-4 show the density distribution over the gap for various N values (indicated on the figures). Figure 1 refers to zero initial electron velocity at the cathode. It is evident that an increase in the number of collisions leads to accumulation of electrons in the gap and to an increase in density. The curves N = 5, 7, 10 are linear at a distance from the boundaries, this corresponding (in the coordinates $\sqrt{x/d}$) to the diffusion approximation. The dashed lines give the results of solving (18) for a density in the center of the gap and a flux taken from the corresponding solutions of the kinetic equation. The solutions of the diffusion equation thus obtained and those of the kinetic equation coincide at a distance from the boundaries. In the Knudsen layer near the cathode, however, the solutions diverge (the effects of the Knudsen anode layer are not apparent in the coordinates used).

It is interesting to compare the density distributions over the gap for various conditions of type a) and b) with nonzero velocities u_0 (dot–dash and dashed curves in Figs. 2-4). The decrease in density near the cathode in case a as compared to b is associated with the fact that in the former case there are no particles emitted by the cathode at velocities directed along the electrodes. This leads to the appearance of characteristic maxima on the corresponding curves. The separation of the maxima from the cathode with increasing initial velocity is associated with the increase in the free path of the electrons. In the diffusion region, there is a tendency for curves re-

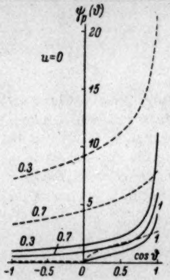

Fig. 6. Distribution functions of scattered electrons with respect to the angle ϑ for $u_0 = 0$: solid curves) N = 2; dashed curves) N = 10; the parameter on the curves represents the distance from the cathode $u = (x/d)^{1/2}$.

ferring to different boundary conditions to converge. The discrepancies here are associated with the unequal effect of the Knudsen anode layer on the electron flux with different boundary conditions.

The flux as a function of the initial velocity u_0 for various N for cases a (dot–dash curves) and b (dashed curves) is shown in Fig. 5. The strongest reflection of electrons from the volume onto the cathode occurs for $u_0 \approx 1$, i.e., for initial electron energy values on the order of the energy acquired in the electric field in passing through the gap. In the limiting cases of small and large initial velocities u_0, the reflection effect attenuates and $i \to 1$. Indeed, for $u_0 = 0$, only those electrons that are scattered in a direction that is strictly perpendicular to the cathode surface can reach the cathode, but the proportion of these electrons is infinitesimal. The increase in the flux as $u_0 \to \infty$ is asociated with the increase in free path, i.e., with the specific assumption regarding the way in which the electron scattering cross section depends on the velocity.

Figures 6 and 7 show distribution functions of monoenergetic electrons with respect to the angle ϑ at various points of the gap ϑ: $\Psi(\vartheta) = (1/n_0)\int_0^{2\pi} \chi(x, W_0, \vartheta, \varphi)d\varphi$ (the parameter shown on the curves is $u = \sqrt{x/d}$). Figure 6 ($u_0 = 0$) and 7a (case a, $u_0 = 0.5$) show the distribution functions $\psi_p(\vartheta)$ of scattered particles. The primary beam, attenuated by collisions, yields a contribution to the distribution function only for $\vartheta = 0$ in these cases, i.e., $\Psi_0(\vartheta) = y_0\,\delta(1-\cos\vartheta)$, and is not shown in the figures. Figure 7b (case b, $u_0 = 0.5$) shows the total distribution function. The solid curves refer to N = 2, while the dashed curves refer to N = 10. For $u_0 \neq 0$ the distribution functions have typical discontinuities at values of the angle $\vartheta = \vartheta_0$ given by the expression

$$\cos\vartheta_0 = \frac{u}{\sqrt{u_0^2 + u^2}} = \frac{e\Phi(x)}{\sqrt{W_0 + e\Phi(x)}},$$

which are particularly pronounced at low collision numbers. The discontinuities are associated with the effect of the boundary. In the case of a beam (Fig. 7a), the sharp decrease in the number of electrons in the interval $0 < \vartheta < \vartheta_0$ is to be explained by the fact that there is no contribution to the distribution function from electrons that have executed reverse trajectories, because of the presence of the electron-absorbing cathode. For an isotropic source at the cathode (Fig. 7b), the presence in the interval $0 < \vartheta < \vartheta_0$ of electrons that leave the cathode without collisions compensates for the effect of absorption of scattered electrons by the cathode and results in an increased number of electrons for these angle values. For large N there are discontinuities only in immediate proximity to the boundary. In the diffusion region, the distribution function depends weakly on the angle and is quasiisotropic.

In conclusion, we consider certain results for thermionic emission from the cathode [boundary conditions of type c]. Using the results obtained for case b and Eq. (12), we compute the density distributions over the gap for various values of $kT/e\Phi_d$. Similar calculations have also been performed for the electron flux. Comparison of the flux as a function of $kT/e\Phi_d$ for case c and of the flux as a function of u_0 for case b shows that the results virtually coincide in both cases if

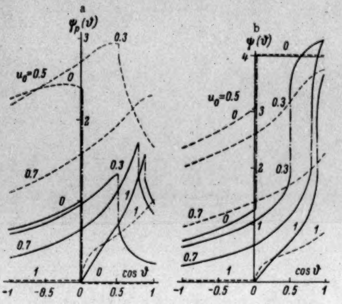

Fig. 7. Electron distribution functions with respect to the angle ϑ for cases a) and b) and with $u_0 = 0.5$.

$$u_0=\sqrt{\frac{3kT}{2e\Phi_d}}.$$

This result is illustrated in Fig. 5, in which the solid curves show the flux as a function of $u_m = \sqrt{v_m/v_d}$, where $v_m = \sqrt{3kT/m}$ is the root-mean-square velocity of the Maxwellian distribution. The greatest discrepancy in the region of the maxima of the curves does not exceed 5%.

Figures 2-4 give a comparison of the concentration distributions over the gap for boundary conditions b (dashed curves) and c (solid curves) for $u_0 = u_m$. It can be seen that there is good agreement here as well, particularly when the initial velocities are not large. The results are associated with the properties of the weighting function with which integration was performed in (12): The basic contribution to the density and flux in case c comes from electrons whose initial energy is on the order of the mean thermal energy of the Maxwellian distribution. As the cathode temperature increases, the weighting-function maximum is spread out, and this results in more pronounced discrepancies in the behavior of the density in cases b and c. These discrepancies are most pronounced near the cathode, but even here the maximum deviation in the curves (for $u_0 = 5$ and N = 10) does not exceed 10%.

Thus, in solving the kinetic equations for electrons with thermionic emission at the cathode we can replace the complex Maxwellian distribution by a simpler monoenergetic isotropic distribution with velocity modulus equal to the root-mean-square velocity as determined by the cathode temperature.

[1)] Similar equations for the case $f_d = 0$ are given in ref. 2.

[2)] Equation (8) can also be used for elastic reflection at the anode. In this case $f_d(v)$ is expressed in terms of the desired distribution function at the anode for $v_x > 0$ from the reflection condition.

A scattering method is used to study a spark in air at atmospheric pressure at times from 1.5 to 60 μsec after the spark is initiated. Radial profiles of the electron density are obtained in a single laser pulse by means of an electron-optical image converter. There is a high electron density in the plasma at distances out to 2 mm from the center of the spark. The dimensions of this region fall off as a function of the time and the density at the center of the spark falls off from $2\cdot10^{18}$ to $3\cdot10^{16}$ cm^{-3}.

We have used a scattering method to study the plasma of a laser spark in air previously, determining the electron temperature and density at the center of the laser spark from the collective-scattering spectrum[1] and determining the radial profile of the electron density.[2] In those experiments we have determined the laser parameters at a single time after the initiation of the spark.

In the present work we have used an electron-optical image converter to obtain radial density distributions in a laser spark at various times. We have studied a laser spark in air at atmospheric pressure at times from 1.5 to 60 μsec after the initiation of the spark.

The image converter makes it possible to obtain the radial profile of the electron density during a single laser pulse. It is therefore possible to avoid errors associated with changes in the parameters of the laser spark from pulse to pulse. It is also possible to obtain certain additional information and to carry out the experiments more rapidly.

EXPERIMENTAL APPARATUS

Figure 1 shows the experimental apparatus used in this study of the plasma of a laser spark by a scattering method involving detection of the radiation by an image converter.

The laser spark arises at the focal point of lens L_1(F = 3 cm), at which the radiation from ruby laser P_1, with an energy of about 1 J, is focused. The radiation from probing laser P_2, P_3 is focused by lens L_2(F = 20 cm) and passes through the spark, intersecting its axis at an angle of 90°. The laser producing the spark and the probing laser are synchronized,[3] by a total-internal reflection prism (R_1).

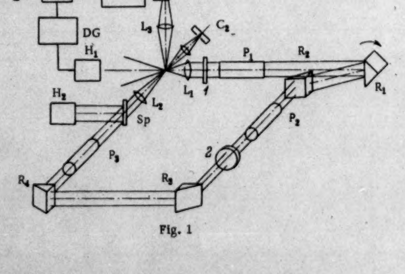

Fig. 1

The scattered radiation is detected at an angle of 90° with respect to the plane passing through the axes of the two lasers. Lens L_3(F = 10 cm) and rotating prism R_5 project the image of the scattering volume on a 1:1 scale onto the entrance slit of monochromator M in such a manner that different parts of the spark in the path of the probing beam are projected onto different vertical points of the slit. The image of the exit slit of the monochromator is focused by lens L_4(F = 9.8 cm) onto the photocathode of an electron-optical image converter (IC). The image obtained on the screen of the converter is photographed by camera C_1.

In addition to photographing the image on the image converter screen, we record oscillograms of both laser pulses, to monitor the laser energy and to determine the delay of the probe laser with respect to the laser producing the spark.

We also record shadow photographs of the spark at the same times, in order to determine the spark dimensions.

Spurious scattered radiation is suppressed by irises placed along the laser path, and the laser spark is enclosed in a light-tight housing. These measures reduce the spurious scattered radiation to a level of less than a few percent of the radiation scattered by the plasma or the air.

A DM-1 diffraction monochromator with a linear dispersion of 22 Å/mm and a relative aperture of 1:10 is used. The widths of the entrance and exit slits of the monochromator are 0.25 and 0.3 mm, respectively, and the slits are 10 mm high.

The radiation is detected by a UMI-93 electron-optical converter operating in the slave mode. The sweep direction is perpendicular to the height of the slit image. The sweep time is 10 μsec. The sweep is triggered by photocell H_1, which receives some of the light from the laser producing the spark. The trigger time is selected by delay generator DG for studying various phases of the spark. The gain of the image converter is set at a value (approximately 30) which provides a sufficient range of measurable radiation intensities at the scattering-signal level in our experiments. The resolution of the converter is at least 10 lines/mm.

The overall spatial resolution along the probing beam is about 0.2 mm. The number of resolvable elements along the laser beam is about 50. The resolution along the observation line is governed by the diameter of the probing laser beam, which is 0.3 mm. The resolution in the third direction is governed by the width of the entrance slit of the monochromator (0.25 mm).

The overall spatial resolution of the system for detecting the scattered radiation is thus about 0.02 mm^3 (0.2 × 0.3 × 0.25).

EXPERIMENTAL PROCEDURE

Figure 2a shows one of the photographs obtained from the screen of the image converter. This photograph shows a time sweep of the radiation passing through the monochromator and striking the photocathode of the image converter. The time axis here is directed from top to bottom. The horizontal axis corresponds to various points along the height of the monochromator slit.

During the early stages of the spark there is spurious scattered radiation from the laser producing the spark. This radiation has the same pulse length as the laser radiation (~ 30 nsec) and the same wavelength (λ = 6943 Å). The monochromator is tuned to this wavelength. The spurious scattered radiation therefore passes through the monochromator, strikes the photocathode of the image converter, and produces a bright band (the horizontal band at the top of the photograph) on the converter screen. The length of this band corresponds to the height of the monochromator slit.

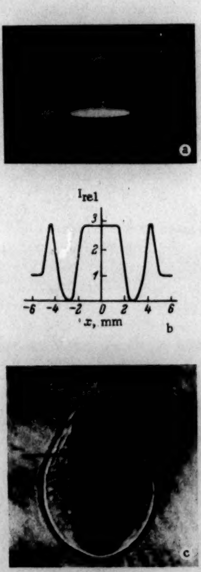

Fig. 2

The broadening of the band due to its displacement on the converter screen is small because of the comparatively low sweep rate; accordingly, the width of this band corresponds approximately to the width of the monochromator slit.

Part of the radiation in the continuous spectrum of the spark itself in the region λ = 6943 Å and within the spectral width of the monochromator slit also passes through the monochromator. This radiation is emitted from the entire volume of the laser spark selected by the entrance slit of the monochromator, and is integrated along the line of sight.

As time elapses, the dimension of the spark along the monochromator slit increases, while the radiation intensity decays. On the time-sweep photograph, accordingly, the light from the spark appears first at the center of the upper horizontal band and expands downward. The resolving time of this sweep is about 300 nsec.

When the probe laser operates, the radiation scattered by the plasma of the spark and by the gas is emitted from only a small volume along the laser beam. The direction of the probing beam penetrating the spark is shown on the shadow photograph in Fig. 2c.

The scattered radiation lies in a narrow spectral region near λ = 6943 Å (its spectral width is much narrower than that of the slit). It passes through the monochromator and forms a bright band on the converter screen (the lower part of the photograph).

The intensity distribution along the bright band corresponds to that of the scattered radiation along the laser beam penetrating the spark. This distribution, obtained with a microphotometer, is shown$^{1)}$ in Fig. 2b. Here, the intensity unit is that of the radiation scattered by air unperturbed by the laser spark.

On both the photograph and in Fig. 2b the intensity profile is radial with good spatial resolution and requires no further Abel analysis. The resolving time here is governed only by the length of the laser pulse and is about 30 nsec.

Figures 2a and 2b show that there is scattered radiation from the central region of a spark. This radiation corresponds to scattering by the plasma with intensity proportional to the electron density. About 2 mm from the center of the spark the electron density falls off, and the intensity of the scattered radiation decays rapidly. We see that the gas density reaches a maximum at the shock front and then falls to the density of the unperturbed gas (air at atmospheric pressure).

Since the cross section for scattering by air is known, we can determine the absolute electron density by comparing the intensities of the radiation scattered by air and by the plasma.

Accordingly, the photograph of the converter screen yields, with good temporal and spatial resolution, the radial profile of the electron density in the plasma, the absolute densities, the radial profile of the gas density, the spark radiation as a function of the time, etc.

The data in Fig. 2 are obtained by probing the spark 2.7 μsec after it is initiated. Figure 3 shows the corre-

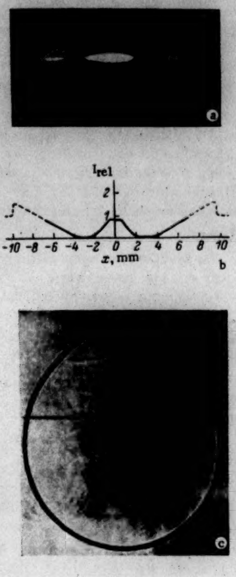

Fig. 3

sponding data for a different time (9.5 μsec). Here the sweep begins later, and the initial stages of the spark are not observed. The shock front has already gone beyond the height of the slit. Its position in Fig. 3b is shown by the dashed curves. The amount of radiation scattered from the central part of the spark in this case is approximately one third that of the preceding case. The electron densities differ by the same factor.

The errors involved in the determination of the absolute electron density consist primarily of the error in the measurement of the relative intensities of the radiation scattered by the plasma and the air and the error in the value of the collective-scattering cross section. In these calculations we assume this cross section to be half the Thomson cross section. The total error in the determination of the absolute electron density is estimated to be about 20%.

The relative electron densities for a given radial distribution are determined much more accurately.

RESULTS AND DISCUSSION

Figure 4 shows radial profiles of the intensity of the scattered radiation at four times, from 2.7 to 50 μsec. Here, as in Figs. 2b and 3b, the intensity unit is the intensity of Rayleigh scattering by unperturbed air. Initially, while the plasma is dense, the radiation scattered by it is several times more intense than Rayleigh scattering by unperturbed air. By 50 μsec the electron density has fallen off markedly, and the radiation scattered by the plasma falls to less than one third the intensity of Rayleigh scattering. We see from the intensity profile for 2.7 μsec that the gas density at the shock front is roughly three times the density of the unperturbed gas. The velocity of the shock front at this time can be determined from a series of shadow photographs taken in succession; it turns out to be 2.5 times the sound velocity in the unperturbed gas. These gas densities and front velocities agree well with shock-wave theory.[4] We therefore adopt the theoretical value for the temperature at the shock front – about 600°K under the present conditions. In a shock wave at this temperature and this density there would be no appreciable dissociation or ionization, so we find more support for the Rayleigh scattering mechanism in the shock wave.

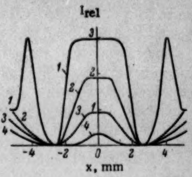

Fig. 4. Radial profiles of the intensity of the scattered radiation. t, μsec: 1) 2.7; 2) 6.5; 3) 9.5; 4) 50.

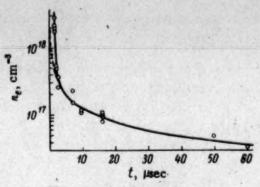

Fig. 5. Electron density at the center of the laser-spark plasma as a function of the time.

Figure 5 shows the change in the electron density as a function of the time for the center of the laser spark. The curve is drawn through the experimental points obtained for various sparks produced by beams with energies from 1 to 1.5 J. We see that from 1.5 to 60 μsec the electron density falls off by about two orders of magnitude. The density changes most rapidly during the first 3 μsec. Subsequently, from 3 to 60 μsec, the electron density decay is slower. Over this time interval the density decay is described by $n_e \sim t^{-0.7}$. This functional dependence, shown by the dashed curve in Fig. 5, merges with the experimental curve from 3 to 60 μsec. The more rapid density decay during the first 3 μsec can be attributed to the high recombination rate. The density decay at the center of the spark after 3 μsec can occur as a result of either recombination or radial expansion of the plasma. If the density decay is due primarily to expansion, as in the case of a laser spark in hydrogen during certain time intervals,[5] the increase in the specific volume as a function of the time under our conditions would be proportional to $t^{+0.7}$. This result agrees with strong-explosion theories.[2)] If, on the other hand, there is appreciable recombination, the increase in the specific volume at the center of the spark should be slower than $t^{+0.7}$.

The electron density in peripheral regions of the spark can be determined as a function of the time from the radial

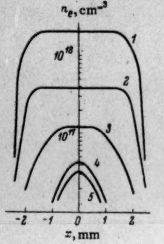

Fig. 6. Radial profiles of the electron density in the plasma of a laser spark. t, μsec: 1) 1.5; 2) 2.7; 3) 9.5; 4) 50; 6) 60.

profiles of the density at various times, from 1.5 to 60 μsec, after the appearance of a spark (Fig. 6). We see from this figure that the profiles are homogeneous at 1.5 and 2.7 μsec. The only important reduction in the electron density occurs in the boundary layer of the plasma in a region less than 1 mm wide. As time elapses, the electron density of the plasma falls off everywhere. The density decays most rapidly in the boundary layer of the plasma.

As a result there is spreading of the boundary layer. The boundary itself, despite the radial expansion, moves toward the center. This result is evidence of rapid recombination at the plasma boundary.

[1)] There is some nonuniformity in the illumination of the slit along its height, because of the slight misalignment of the slit with respect to the probing beam; this misalignment is difficult to avoid. This nonuniformity is taken into account in the analysis of the results.

[2)] According to strong-explosion theory[6] the specific volume is $v = 1/n_e \sim t^{6/5\gamma}$; if the ratio of specific heats $\gamma = C_p/C_v = 5/3$, we have $v \sim t^{0.72}$.

Extraction of the proton beam from the 70-GeV accelerator of the Institute of High-Energy Physics for the Ludmila liquid-hydrogen chamber is described. The features of the beam extraction and transport systems, the design parameters, the tolerances, and the characteristics of the apparatus are discussed. The method used to align the system is discussed. The results of the alignment of the system are reported.

1. THE EXTRACTION SCHEME

To obtain the separated beams of secondary particles used in experiments with the Ludmila liquid-hydrogen chamber, the overall scheme[1] for extracting protons from the 70-GeV accelerator includes a provision for fast extraction in the S direction. According to the operating conditions of the radio-frequency (rf) separator, the extraction should last no more than 5 μsec, i.e., the beam must be extracted during one orbit or less. The operating conditions of the rf separator impose extremely rigid requirements on the characteristics of the beam focused on the external target and on the stability of these characteristics from cycle to cycle. The beam at the outer target must be no more than 1.5 mm in the vertical direction and 2 mm in the horizontal direction, with an angular divergence no larger than ± 2.5 mrad. The instability in the beam position must be better than ± 0.2 mm.

The basic principles used in the design of the fast-extraction system S and the beam-focusing system are described in ref. 2. Figure 1 shows the scheme for extracting the beam from the accelerator chamber. The apparatus used previously to extract protons in the direction of the Mirabel' chamber[3] (extraction system A) is used in this scheme. The fast extraction is achieved with pulsed magnet PM 16, in linear gap 16. Here, the field increases and decays during the time between the passages of successive bunches of the accelerated beam. The pulsed magnet deflects the beam into the gap of movable septum magnet DM 24. This magnet is inserted into the working part of the accelerator before the extraction section, being located at the inner edge of the accelerated beam. In this manner the deflection angle required in the pulsed magnet can be minimized. Magnet DM 24 deflects the beam into the gap of septum magnet DM 26; the field strength in the latter magnet determines whether the beam is extracted from the accelerator into linear gap 28 or 30. In these gaps, outside the vacuum chamber, are deflecting magnets DM 28 and DM 30, which deflect the extracted beam either toward the Mirabel' bubble chamber (extraction system A) or toward the Ludmila bubble chamber (extraction system S). This system provides rapid extraction of protons with an efficiency near 100% over the energy range 30-75 GeV. The system operates three times in each acceleration cycle; the extraction can be in different directions or in the same direction. In each extraction from 1 to 30 bunches of the accelerated beam can be extracted. The extraction time can be adjusted correspondingly from 15 nsec to 5 μsec. The energy level can also be varied from extraction to extraction.

The system for extracting the beam toward the Mirabel' chamber was put into operation in February 1972; it is described in detail elsewhere.[3,4] Below we summarize the work on extraction toward the Ludmila chamber; this extraction system was put into operation in October 1972.

2. FOCUSING SYSTEM

Figure 2 shows the arrangement of the elements of the system for transporting the extracted beam to the ex-

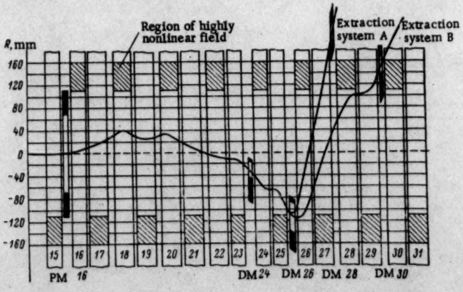

Fig. 1. Scheme for fast extraction of protons from the accelerator.

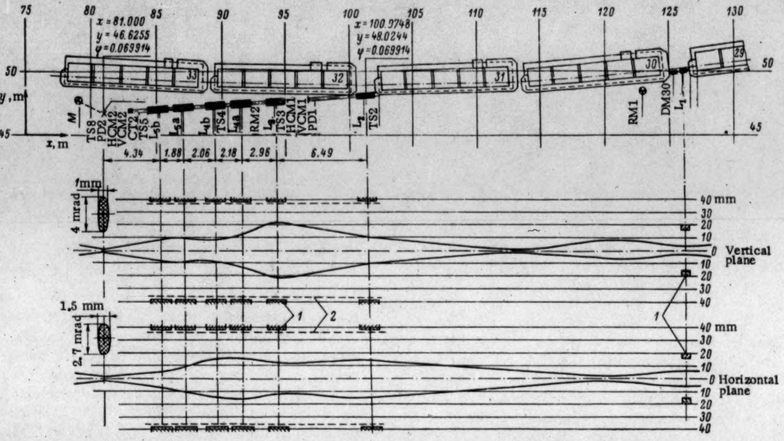

Fig. 2. Arrangement of the apparatus in the region in which the beam is transported to the external target. ternal target, which is 45 m away from the extraction point. More than 20 m of the trajectory of the extracted beam is in the fringing field of units 30 and 31. A quadrupole focusing lens L_1 is located in linear gap 30 in front of deflecting magnet DM 30 to compensate for the strong defocusing effect of the fringing field in the horizontal direction. Immediately after the extraction into "free space," in linear gap 32, is lens L_2, which prevents an extreme increase in the beam dimensions at the entrance to the triplet lens L_3, L_4, L_5.

The design of the optical system takes into account the actual characteristic of the accelerated beam as determined experimentally.[5] The design emittance in both planes is taken to be π mm · mrad. Since very rigid requirements are imposed on the beam focusing, careful account is taken of the accelerator magnetic field, the characteristics of the fringing field of the main magnet, and the actual characteristics of the magnets and lenses in the transport system. The extraction trajectory is completely outside regions with highly nonlinear magnetic fields. In calculation related to the motion within the working region of the accelerator (± 10 cm from the central orbit) the magnetic field is specified on the basis of the results of the magnetic measurements. The nonlinear terms of up to the fifth order, inclusively, in the expansion of the magnetic field are taken into account. The equations of motion are integrated numerically on a BÉSM-6 computer. The motion of the extracted beam in regions more than 10 cm radially away from the central orbit is calculated on the basis of a program in which the magnetic field is specified on the basis of a map plotted with an error no worse than ± 0.5% (ref. 6).

The parameters of the focusing system are chosen to minimize the dimensions of the beam envelope in both planes and thus to minimize the effects of the nonlinearities in the lenses and magnets. Figure 3 shows the beam dimension at the entrance to lens L_2 as a function of the gradient in lens L_1. A gradient of 65 T/m is chosen; this value minimizes the horizontal dimension of the beam at the entrance to lens L_2. The gradients in lenses L_2–L_5 are calculated on a computer by a program which allows the initial phase ellipse of the beam to be transformed in such a manner ellipse of the beam to be transformed in such a manner that a crossover with specified dimensions in both planes is achieved at the external target. The numerical values of the matrix elements for the transport along the extraction trajectory within the accelerator and in the fringing-field region are also calculated on a computer. Figure 4 shows the gradients in lenses L_2–L_4 as functions of the dimensions of the beam at the external target. The design dimensions are 1 mm (vertical) and 1.5 mm (horizontal) chosen on the basis of the beam spreading at the target due to instabilities in the magnet and lens currents and due to nonlinearities. For this case Fig. 2 shows the envelopes of the beam in both planes, the beam dimensions, and the angular divergence at the external target corresponding to an initial emittance of π mm · mrad.

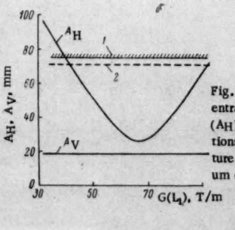

Fig. 3. Dimensions of the beam at the entrance to lens L_2 in the horizontal (A_H) and vertical (A_V) planes as functions of the gradient in lens L_1. 1) Aperture of lens L_2; 2) aperture of the vacuum chamber.

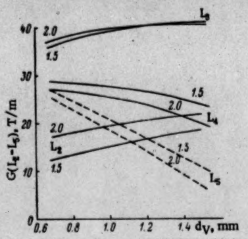

Fig. 4. Gradients in lenses L_2-L_4 for various horizontal (d_H) and vertical (d_V) dimensions of the beam at the external target. Here the parameter is d_H, in millimeters.

Since the transport system is long, methods have been worked out for correcting the direction and position of the extracted beam. In the horizontal plane the beam is guided by magnet DM 26 to the center of the exit window, in front of linear gap 30. After passing through lens L_1 the beam enters magnet DM 30, which deflects it to the center of correcting magnet HCM1. This magnet brings the beam into exact coincidence with the optical axis of the triplet lens. In the vertical plane the beam is guided along the center of the exit window by means of a local distortion of the vertical orbit of the circulating beam in the extraction region. Figure 5 shows the shape of the local distortions produced by two pairs of polar correcting windings of the main magnet of the accelerator. The distortion produced by windings 27 and 33 is intended to correct the extraction coordinate. That produced by windings 24 and 30 is intended to correct the vertical angle of the beam extraction. Through an appropriate choice of the currents in the two pairs of windings the beam can be guided exactly to the center of the exit window, at an extraction angle bringing the beam to the center of the triplet lens. If necessary, the beam axis can be brought into coincidence with the triplet axis by means of vertical corrector VC1. The pair of correcting magnets HCM2 and VCM2 in front of the external target regulates the point and angle at which the extracted beam is incident on the target, in such a manner that the secondary particles formed by the beam are guided exactly along the channel axis in the rf separator.

3. BASIC CHARACTERISTICS OF THE APPARATUS

Table 1 shows the characteristics of the magnets and lenses in extraction system S. The pulsed magnet is a C-shaped ferrite magnet consisting of 10 sections. The single-turn winding is made from flat conductors. Each section is connected to a separate pulse generator. The field in a section of the magnet is excited by discharging an artificial storage line charged to 80 kV. The rise time of the current in the magnet is less than 150 nsec. The pulse length can be varied from 15 nsec to 5 μsec. Septum magnets DM 24 and DM 26 are of basically the same design, differing in the aperture dimensions. Their C-shaped cores are made from transformer iron. The single-turn windings of the magnets have an external conductor which is a thin partition (or septum), 3 mm thick for DM 24 and 5 mm thick for DM 26. Magnet DM 24 is movable. In each acceleration cycle it is inserted into the working region of the accelerator by a hydraulic system, which moves it 100 mm in 0.3 sec. The error of the positioning of the magnet in its working position is ± 0.5 mm. The pulsed magnet and the septum magnets were constructed at CERN and are described in detail elsewhere.[7,8] The other magnets and lenses have been developed in the Scientific-Research Institute for Electrophysical Apparatus. Deflection magnet DM 30, of type SP 143, is a C-shaped magnet with an aperture 40 mm wide and 32 mm high. It is constructed from stacks of iron-alloy plates 3 mm thick. Since the magnet is in the immediate vicinity of the accelerator, measures are taken to reduce its fringing field outside the gap. For this purpose a high-permeability partition is placed at the edge of the gap. This magnet will be used in the future in the slow-extraction

system, so its power supply shapes trapezoidal current pulses, at amplitudes up to 2 kA and with flat parts up to 1 sec long. The flat parts of the current pulses are regulated within ± 0.1%.

The transport system includes quadrupole lenses of two types. For the preliminary focusing, lens L_1 is a 3K70 lens with an aperture 30 mm in diameter. The other six lenses, of type 7.5K150A, have apertures 75 mm in diameter. All the correcting magnets are the same type and have apertures 58× 80 mm in size. The lenses and magnets of the transport system are pulsed. They are made from stacks of iron-alloy plate 0.5 mm thick. The power supplies feeding the magnets and lenses produce unipolar sinusoidal current pulses with amplitudes up to 5 kA and a half-period of about 10 msec. The amplitudes of these current pulses are regulated within ± 0.1%. Lens L_1, like magnet DM 30, will be used in the future in the slow-extraction system, so the corresponding power supplies are similar.

We have carefully studied the magnetic characteristics of each element. The magnetic-measurement program includes measurement of the gradient G_0 at the center of the lens, at its axis, as a function of the excitation current. It also involves measurement of the effective length of the lens, $L_{\mathrm{eff}} = (1/G_0)\int_{-\infty}^{\infty}(dB/dx)_{x=y=0}dz$. In the 7.5K150A lenses, the value of L_{eff} falls off by less than 1% when G_0 is changed from 6 to 40 T/m. The deviations in the values of L_{eff} from sample to sample are less than ± 0.2%. The induction components of the magnetic field of the lens can be written in terms of polar coordinates (r, φ) as the harmonic series

$$B_r = -\sum_{k=1}^{\infty} A_k r^{k-1} \sin(k\varphi + \varphi_{0k}), \tag{1}$$

$$B_\varphi = -\sum_{k=1}^{\infty} A_k r^{k-1} \cos(k\varphi + \varphi_{0k}), \tag{2}$$

where k is the index of the harmonic and φ_{0k} is the initial phase of harmonic k. We measure the relative integrated amplitudes of the harmonic components

$$\gamma_k = \frac{\int_{-\infty}^{\infty} A_k dz}{\int_{-\infty}^{\infty} A_2 dz} a^{k-2}$$

at aperture radius a. The error in the γ_k measurements for the fundamental harmonics is ± 0.01%. Typical measured values of γ_k and φ_{0k} for the two types of lenses are shown in Table 2.

Figure 6 illustrates the results of the measurements with curves of the relative deviation of the integral gradient along the transverse axes x and y for a 7.5K150A lens; these curves are plotted from the results of the harmonic analysis:

$$\frac{\Delta\int G_x dz}{\int G_x dz} = \frac{\int_{-\infty}^{\infty}\left(\frac{dB_y}{dx}\right)_{x,y} dz - \int_{-\infty}^{\infty}\left(\frac{dB_y}{dx}\right)_{x=y=0} dz}{\int_{-\infty}^{\infty}\left(\frac{dB_y}{dx}\right)_{x=y=0} dz}, \tag{3}$$

$$\frac{\Delta\int G_y dz}{\int G_y dz} = \frac{\int_{-\infty}^{\infty}\left(\frac{dB_x}{dy}\right)_{x,y} dz - \int_{-\infty}^{\infty}\left(\frac{dB_x}{dy}\right)_{x=y=0} dz}{\int_{-\infty}^{\infty}\left(\frac{dB_x}{dy}\right)_{x=y=0} dz}. \tag{4}$$

We measure the displacement of the longitudinal magnetic axis of the lens from the geometric axis in two transverse cross sections; the error of these measurements is ± 0.02 mm. We find that the displacement does not exceed ± 0.1 mm in either cross section.

For the correcting magnets we measure the magnetization curves, the effective length along the field, and the

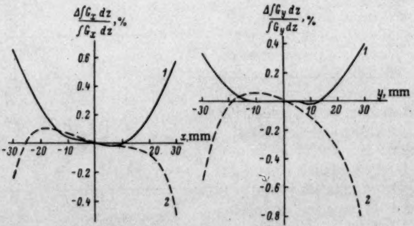

Fig. 6. Relative deviations of the integral gradient for a 7.5K150A lens at 20 T/m (curve 1) and 40 T/m (curve 2).

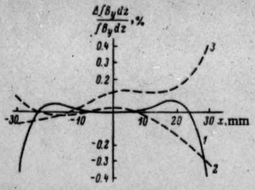

Fig. 7. Relative deviation of the integral field for an SP 147 magnet, measured in the median plane (curve 1), in the plane y = +15 mm (curve 2), and in the plane y = −15 mm (curve 3) at an induction of 1.8 T.

relative deviation of the integral field along the length of the magnet. Figure 7 shows typical curves of the relative deviation in the integral field for an SP 147 magnet, measured along the x axis in different vertical planes at an induction of 1.8 T. We see that the deviations do not exceed ± 0.5% in the working region.

Figure 2 shows the layout of the apparatus along the trajectory of the extracted beam. All the magnets and lenses have separately adjustable mounts. The correcting magnets and five triplet lenses are on a common mount for ease in adjustment. The external target, on a separate mount, can be moved accurately in the horizontal and vertical directions by remote control. The target is on a ring mount with a horizontal rotation axis. The removable ring is fitted with six holders, which can hold various targets for producing secondary particles, television screens for monitoring the beam, sets of foils for activation, and other measurement devices. The target is mounted in a junction in the vacuum line between correcting magnet HCM2 and the secondary-particle duct. Calculations have shown that a degradation of the vacuum along the extraction trajectory, even in a limited region, strongly affects the dimensions and emittance of the beam which is focused on the target. Accordingly, a forevacuum as high as 10^{-1} torr is maintained along the entire trajectory, beginning from the point at which the beam leaves the accelerator. The evacuated ion duct is made of stainless-steel tubing.

Television screens are mounted at the entrance to the extracting magnets, at characteristic points in the transport system, and on the external target for monitoring the beam. A PTU-103M industrial television system is used for remote monotoring of these screens. In this manner it is possible to monitor the dimensions, shape, and position of the extracted beam. The screens are moved into their working positions by electric drives. The metallic substrate is less than 0.3 mm thick so that it is possible to monitor on the basis of three screens simultaneously. More accurate operational control of the beam position is achieved with magnetic position sensors mounted at the entrance to the triplet and in front of the target. The beam intensity is measured with current transformers at the exit from the accelerator and in front of the target; there is also a reference current transformer in the accelerator ring. These detectors can measure the intensity in each bunch of the accelerated beam which is to be extracted, so it is possible to determine the extraction efficiency and the beam loss in the transport system. A Cerenkov detector which measures the particle flux from the target is used to monitor the adjustment of the channel and the efficiency of the interaction of the beam with the external target. The charge of the electrons ejected from the target bombarded by the proton beam is also measured. For this purpose the target is insulated from its holder; the resistance of the insulation is better than 10^9 Ω. Radiation monitors are mounted near narrow regions along the extraction trajectory to detect loss resulting from deviations from the normal extracting and focusing conditions. These monitors, which use scintillation detectors, generate signals proportional to the total loss. When the signal exceeds a specified level, a warning system is activated, and further operation of the fast-extraction system is blocked.

Operation of the extraction system is synchronized with the acceleration cycle by the B and T series of accelerator pulses.[9] The common B pulse, which corresponds within $\pm 5 \cdot 10^{-4}$ to the specified magnetic field, is selected in order to achieve the necessary accuracy in the synchronization of the fast-extraction system, the beam-transport system, the rf separator, and the Ludmila chamber. Time is measured with respect to this pulse by means of the T series of pulses, within $\pm 10^{-4}$. With the prevailing instability in the rate of increase of the magnetic field in the accelerator from cycle to cycle, this synchronization method makes it possible to select an extraction energy reproducible within less than $\pm 10^{-3}$.

4. ALIGNMENT OF THE SYSTEM

The lenses in the focusing system are arranged in accordance with the results of magnetic measurements. Samples with slight nonlinearities are used for lenses L_3 and L_4. Since the beam envelope reaches its maximum value in these lenses, nonlinear components of the field in these lenses have the greatest effect on the focusing. The effect of the field nonlinearities in the lenses on the characteristics of the beam focused on the external target is calculated on a BÉSM-6 computer. The system of the general equations of motion for protons having a specified momentum in the magnetic field is integrated over the effective length of the lens. The field in each lens is specified on the basis of the measurements through Eqs. (1) and (2). Figure 8 shows how the beam characteristics

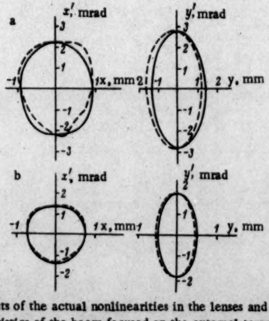

Fig. 8. Effects of the actual nonlinearities in the lenses and magnets on the characteristics of the beam focused on the external target at emittances of 2π mm • mrad (a) and π mm • mrad (b).

TABLE 3

Unit	Instability factor	Magnitude of instability, %	Increase in beam dimension (divergence)					
			in lenses*		at target			
			ΔA_r	ΔA_z	Δr	Δz	$\Delta r'$	$\Delta z'$
			mm		mm		mrad

*At the maximum of the envelope of the beam in the transport system.

at the external target are distorted by nonlinearities for two initial emittances of the accelerated beam. We see that with the selected lens arrangement the effect of these nonlinearities on the beam with an emittance of π mm · mrad is negligible. At an emittance 2π mm · rad the distortions are more significant, but even in this case the spreading of the beam at the target does not exceed ± 0.1 mm.

The magnetic field in the gap is specified by a map to evaluate the effect of inhomogeneities of the magnetic field in the correcting magnets. We find that inhomogeneities below 1-2% have no significant effect on the beam characteristics at the crossover.

Instability of the beam characteristics in the accelerator and instability of the power supplies for the lenses and the magnets affect the stability of the dimensions and position of the beam at the target. Table 3 summarizes the values of the possible changes in the beam characteristics at the target and in the beam size at the maximum envelope resulting from various instability factors.

The magnitudes of the current instabilities in the magnets and the lenses are based on the results of the alignment. Computer calculations are carried out to determine the beam spreading at the target corresponding to a change in the current at each element. For the instability values given in Table 3 the beam spreading at the target in the horizontal and vertical directions is negligible. The instability in the position of the beam at the target is also small, less than ± 0.1 mm.

Instability in the operation of the accelerator is more important. The most dangerous instability is an increase in the emittance of the accelerated beam. At one time the accelerator of the Institute of High-Energy Physics suffered from an anomalous beam spreading at the end of acceleration due to the nonlinear resonances $3Q_z = 29$, $2Q_z + Q_r = 29$, and $3Q_r = 29$. Modifications were made to achieve conditions more favorable for beam extraction and focusing:[5] During the entire acceleration cycle the working point on the diagram of synchrotron-oscillation frequencies is held in a region free of resonances. The beam is accelerated at the central radius, and the appropriate behavior of the currents in the polar windings correcting the magnetic-field gradient was found for this beam position. These measures reduce the emittance of the accelerated beam to π mm · mrad. The stability of the emittance in prolonged operation of the accelerator is also improved.

The radial position of the accelerated beam is stabilized by a feedback system using a position sensor in linear gap 15. In prolonged operation the instability of the radial position of the accelerated beam is less than ± 0.5 mm. The scatter in the energy values from cycle to cycle, governed by the error in the synchronization of the extraction time with the selected magnetic field in the accelerator, is less than ± 0.1%.

The geometric axis of the transport channel is brought into vertical coincidence with the median plane of unit 29 and with the axis of the secondary-particle channel. The centers of the lenses, magnets, television screens, position sensors, and external target are within 0.2 mm of this axis. The adjustments are made with respect to the aligned extraction trajectory. Because of the alignment of the fast-extraction system and the transport channel it is found that the extraction trajectory and the beam trajectory in the fringing field coincide with the design trajectory all the way to the external target. The center of the extracted beam is brought accurately into coincidence with the center of lens L_1 by magnet DM 26. The accuracy of this alignment is checked by changing the current in lens L_1: When the beam is correctly aligned with respect to the lens axis, a change in this current does not displace the beam on screen TS2. The beam displacement from the calculated trajectory does not exceed 3 mm over the entire trajectory, even without the additional correction; the correcting elements easily eliminated this error.

As the working conditions we select the calculated version of the focusing which leads to a beam having a horizontal dimension of 1.5 mm and a vertical dimension of 1 mm at the target. The calculated lens currents are achieved within $\pm 5 \cdot 10^{-4}$. Figure 9 shows the distribution of the beam intensity at the external target in both planes, obtained by the method of foil activation. For these measurements we use 10 × 10 mm stacks of aluminum foil 0.1 mm thick. The foil is irradiated over 100 cycles by the corresponding extracted bunches of the ac-

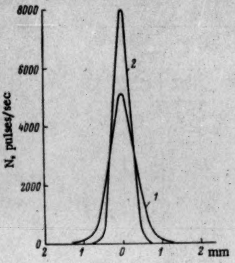

Fig. 9. Intensity distribution of the beam focused on the external target in the horizontal (curve 1) and vertical (curve 2) planes at an energy of 70 GeV.

celerated beam; then the activity induced in each of the foils is measured. The instability in the position of the beam center at the external target does not exceed ± 0.2 mm.

The beam dimensions at intermediate points in the transport system, determined with the television screens, agree well with the beam envelope shown in Fig. 2. At the optimum alignment of the system the extraction efficiency, defined as the ratio of the number of particles in the extracted bunches to the number of particles in the same bunches 150 μsec before extraction, is 97-98%. The beam is extracted from the accelerator chamber essentially without loss. In the magnets and lenses of the transport system there is much free space to spare, so the beam also passes through this system without loss. This is verified by the indications of the loss monitors mounted at all the narrow regions in the extraction trajectory, at the entrance to lens L_1, and in the transport system. When the system is aligned correctly, these monitors detect no beam loss. However, when the extraction efficiency falls off a few per cent, the point at which the loss occurs can be readily detected by these monitors.

Particles with energies from 30 to 70 GeV have been extracted and focused onto the external target. The results agree well with the calculations. The beam parameters at the external target satisfy the requirements imposed for operation of the rf separator.

In conclusion the authors thank all their colleagues who participated in the planning, construction, and alignment of the apparatus and who helped ensure the success of this work.

Holography

Imaging properties of traveling intensity waves in the recording of dynamic three-dimensional holograms

Yu. N. Denisyuk

(Submitted July 3, 1973)
Zh. Tekh. Fiz., 44, 131-137 (January 1974)

The properties of traveling intensity waves produced by the interference of radiation at different frequencies are investigated. It is shown that a spatial material model of a traveling wave formed by the addition of object radiation and a reference wave is analogous to a hologram in that it has the property of transforming the reference wave into the object-scattered radiation wave. The only difference is that the dynamic traveling wave model reproduces not only the amplitude, phase, and spectral composition, but also the frequency shift of the object wave relative to the reference wave. In this case, moreover, the spectral composition of the radiation corresponding to the pseudoscopic image is distorted by the Doppler effect. A theory is formulated for the effect on the basis of a solution of the wave equation in the first perturbation approximation and on the assumption that the detecting wave does not affect the structure of the hologram. A detailed analysis of the mechanism of the effect is also given in the special example of the interference of two plane waves at different frequencies. The effect can be used for the design of radiation converters as well as in real-time data-processing devices.

It has been shown[1-3] that a three-dimensional material model of a standing wave produced in the space around an object by the addition of the incident and scattered radiation is a kind of optical equivalent of that object, i.e., such a model has the capacity to affect the radiation in the same way as the object. We show in the present work that the effect is not restricted to the special case in which standing wave patterns are recorded and that imaging properties are inherent in any intensity waves, including traveling waves such as those produced in the recording of a moving object, where the wavelength of the scattered radiation is shifted relative to that of the incident radiation due to the Doppler effect.

We first investigate as a special example the singular features of the interference of two waves of different frequencies. We assume that two waves characterized by different values of the wave vector k and the frequency intersect in space.

The wave functions for these waves can be described by the expressions

$$\Psi_1(r, t) = a_1 e^{i(\mathbf{k}_1\mathbf{r} - \omega_1 t + \varphi_1)}, \tag{1}$$

$$\Psi_2(r, t) = a_2 e^{i(\mathbf{k}_2\mathbf{r} - \omega_2 t + \varphi_2)}. \tag{2}$$

The total intensity field of the waves is found by adding Ψ_1 and Ψ_2 and multiplying the result by the complex conjugate. We have

$$J(r) = a_1^2 + a_2^2 + 2a_1 a_2 \cos[\varkappa\mathbf{r} - \Omega t + (\varphi_1 - \varphi_2)], \tag{3}$$

where

$$\begin{gathered} \varkappa = \mathbf{k}_1 - \mathbf{k}_2, \\ \Omega = \omega_1 - \omega_2. \end{gathered} \tag{4}$$

Equation (3) is analogous in form to Eqs. (1) and (2) and also describes a plane traveling wave; in the given case, however, this wave is an intensity wave. We determine its propagation velocity by setting the argument of the cosine equal to a constant and then taking the derivative of the projection of the radius vector r by the wave vector $\varkappa$ for the intensity wave:

$$v = \frac{1}{|\varkappa|}\frac{d\varkappa\mathbf{r}}{dt} = \frac{\Omega}{|\varkappa|}. \tag{5}$$

We find the spatial period of the intensity wave Λ by means of an expression analogous to the relation between the wavelength λ and wave number k:

$$\Lambda = \frac{2\pi}{|\varkappa|}. \tag{6}$$

For the special case in which the interfering waves propagate in approximately opposite directions and their wavelengths differ only slightly Eqs. (5) and (6) describe a structure very similar to an ordinary standing wave. In this case,

$$v \approx \frac{\Omega}{2k}, \quad \Lambda \approx \frac{\lambda}{2}. \tag{7}$$

Inasmuch as $k = \omega/c$ and $\Omega \ll \omega$, we have $v \ll c$.

Consequently, the spatial period of the given intensity wave, as in the ordinary standing wave, is approximately equal to half the wavelength of the incident radiation. The only difference is that the given structure moves through space at a speed proportional to the frequency difference between the interfering waves.

Assume that a traveling intensity wave is recorded in a photosensitive medium, whose time constant τ satisfies the following conditions: It is greater than the period T of the light wave, so that the material medium does not reproduce intensity oscillations occurring at the optical frequency:

$$\tau > T = \frac{2\pi}{\omega}. \tag{8}$$

We assume in addition that the time constant τ is much smaller than the oscillation period of the intensity wave in its motion as a unit:

$$\tau \ll t = \frac{\Lambda}{v}. \tag{9}$$

Substituting the values of Λ and v from (5) and (6) into

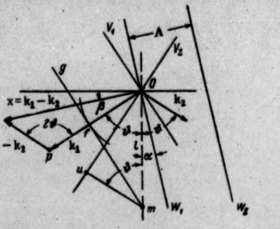

Fig. 1. Interaction of radiation with a material model of a traveling plane intensity wave. V_1, V_2) Interfering plane waves; k_1, k_2) wave vectors of V_1 and V_2; W_1, W_2) frontal surfaces of the traveling plane intensity wave; $\varkappa$) wave vector of W; Λ) spatial period of W.

(9), we obtain the foregoing condition in the form

$$\tau \ll \frac{2\pi}{\omega_1 - \omega_2}. \tag{10}$$

It is readily perceived that when conditions (8) and (10) are satisfied a traveling material harmonic occurs in the photosensitive medium, modeling the intensity distribution described by Eq. (3). Thus, in accordance with condition (8) the medium does not reproduce high-frequency intensity oscillations, so that the operation of multiplication of the wave function by its complex conjugate can be used in the calculation of the actual intensity. On the other hand, the intensity variations corresponding to wave propagation will be reproduced on account of condition (10).

We now analyze the interaction of radiation with the aforementioned harmonic in the first perturbation approximation, neglecting secondary scattering effects and the attenuation of the incident wave in its propagation through the volume of the hologram. We assume for simplicity that light is reflected only by antinode surfaces, i.e., we represent the harmonic as a set of parallel mirrors separated by a distance Λ and moving at a speed v [see Eqs. (5) and (6)]. The schematic arrangement of these mirrors (which we refer to hereinafter as "isophase") is given in Fig. 1. Here $\mathbf{k}_1$ and $\mathbf{k}_2$ are the wave vectors of the interfering plane waves V1 and V2, and W_1 is the intensity wave front surface, which after recording is converted into one of the isophase mirrors. This surface is perpendicular to its "wave vector" $\varkappa = \mathbf{k}_1 - \mathbf{k}_2$. Unlike the case of an ordinary standing wave, as the figure indicates, the surface W_1 does not coincide with Om, the bisector of the angle formed by the vectors $\mathbf{k}_1$ and $\mathbf{k}_2$. The direction of motion of the wave W_1 determines the vector $\varkappa$; the wave moves either in the direction of $\varkappa$ or in the opposite direction. The sign of the motion can be determined on the following basis. If $|\mathbf{k}_1| > |\mathbf{k}_2|$, the value of $\Omega = \omega_1 - \omega_2$ is positive, whereupon in accordance with (3) W_1 moves in the direction indicated by the vector $\varkappa$. If $|\mathbf{k}_1| < |\mathbf{k}_2|$, the sign of Ω changes, and the wave moves in the opposite direction. As is evident from the figure, this rule is in fact equivalent to saying that the intensity wave moves in the general direction of motion of the field wave characterized by the larger absolute value of the wave vector $\mathbf{k}$.

It may appear at first glance that the given system of isophasal mirrors does not have the attributes of a hologram, i.e., that it is incapable of transforming one of its formative waves into the other. Indeed, since the mirror surface W_1 is not the bisector of the angle formed by $\mathbf{k}_1$ and $\mathbf{k}_2$, a wave traveling in the direction of $\mathbf{k}_2$, according to the conventional laws of specular reflection, cannot be transformed into a wave traveling in the direction of $\mathbf{k}_1$. Also, it is readily noted that the distance Λ, Eq. (6), between the planes of the adjacent mirrors does not satisfy the Bragg condition, and this fact would seem to reaffirm the impossibility of the wave V_2 being transformed into V_1 or vice versa.

A more detailed analysis shows, however, that all of these effects are only apparent. When radiation is reflected from a moving mirror, Snell's law is violated, the angle of incidence being no longer equal to the angle of reflection. It turns out that the change of the reflection angle in the given situation is such as to ensure the possibility of mutual transformation of the waves V_2 and V_1. We now examine the latter effect in closer detail.

Suppose that one of the waves, say V_2, forming the moving isophasal mirror W_1 is incident on that mirror. We show that the motion of the mirror causes the wave V_2 to encounter the surface of the mirror along the bisector Om of the angle formed by the vectors $\mathbf{k}_1$ and $\mathbf{k}_2$. We are required to prove that the wave front, which intersects the mirror at the point O at the initial time $t = 0$, intersects an arbitrary point m of the bisector Om at precisely the time $t_1 = t_2$ when the moving isophasal mirror W_1 passes across it.

The latter condition is formally equivalent to requiring that the propagation times of the wave fronts W_1 and V_2 be equal up to the point m. Writing $Om = l$, and denoting the corresponding times by t_1 and t_2, we write this condition as follows (see Fig. 1):

$$t_1 = \frac{l \cos\vartheta}{c}, \tag{11}$$

$$t_2 = \frac{l \sin\alpha}{v}. \tag{12}$$

We find the angle α describing the deviation from the specular reflection law. From the triangle tpO we find

$$\sin\beta = \frac{k_2}{\varkappa} \sin 2\vartheta. \tag{13}$$

Then, taking account of (13), we write the following expression for sin α:

$$\sin\alpha = \cos(\beta + \vartheta) = \frac{\cos\vartheta \left\{\sqrt{\varkappa^2 - k_2^2 \sin^2 2\vartheta} - 2k_2 \sin^2\vartheta\right\}}{\varkappa}. \tag{14}$$

We use the triangle Otp to determine the value of $\varkappa^2$:

$$\varkappa^2 = k_1^2 + k_2^2 - 2k_1k_2 \cos 2\vartheta. \tag{15}$$

Substituting (15) into (14), we obtain

$$\sin\alpha = \frac{\cos\vartheta \left\{\sqrt{k_1^2 + k_2^2 - 2k_1k_2 \cos 2\vartheta - k_2^2 \sin^2 2\vartheta} - 2k_2 \sin^2\vartheta\right\}}{\varkappa}. \tag{16}$$

It can be shown that the expression under the square root in (16) reduces to the form

$$(k_1+k_2-2k_2\cos^2\vartheta)^2.$$

With this fact in mind we obtain

$$\sin\alpha=\frac{(k_1-k_2)\cos\vartheta}{x}. \tag{17}$$

Substituting the value of sin α from (17) along with the value of v into (12) with allowance for (15), we readily verify that $t_1 = t_2$ and that, therefore, the wave fronts W_1 and V_2 occur simultaneously at the point m. Inasmuch as the choice of the position of m on the bisector Om is entirely arbitrary, it is obvious that all other points of the bisector are points of impingement of the fronts V_2 and W_1. Under these conditions the wave reflected by the isophase mirror W_1 is very easily constructed by the Huygens principle (see Fig. 1). The wave V_2 is tangent to the mirror W_1 at the point O at the initial time t = 0. At that time a spherical wave emanates from the point O. In the time that it takes for the wave V_2 to reach the point m of the mirror the spherical wave emanating from the point O traverses the path um. Drawing the tangent to the spherical wave surface from the point m, we find the reflected wave V_2'. Consider the triangles Ofm and Oum. Inasmuch as their legs Of and um are equal and they share a common hypotenuse, they are congruent. It follows, therefore, that the angle fOm is equal to v and that the reflected wave V_2 moves in the direction of the vector k_2', i.e., is transformed into the second wave participating in the formation of the set of moving isophasal mirrors.

It can be shown by analogous constructions that the motion of the mirror W_1 being opposite to that of the wave with the smaller wave vector upon reflection the latter acquires a frequency shift such that the reflected wave reproduces not only the direction, but also the frequency of the second interfering component. To complete the proof it is also required to show that the Bragg condition is also satisfied. However, we shall not carry out the laborious constructions needed for this proof; we proceed instead to the more formal investigation of the general case in which a traveling intensity wave is formed by the interference of a reference wave with a complex in general, arbitrary, radiation wave scattered by an object.

Let the wave functions of the incident radiation and the radiation scattered by the object be given by the expressions

$$\Psi_r(rt)=\psi_r(r)e^{i\omega_r t} \tag{18}$$

$$\Psi_0(rt)=\psi_0(r)e^{i\omega_0 t}. \tag{19}$$

The intensity distribution function for the field surrounding the object is determined by adding (17) and (19) and multiplying the result by the complex conjugate. We also assume that under the action of the field the dielectric constant ε of the medium acquires an increment $\delta\varepsilon$ proportional to the perturbing intensity:

$$\varepsilon=\varepsilon_0+\delta\varepsilon, \tag{20}$$

where

$$\delta\varepsilon=\Psi_r\Psi_r^*+\Psi_0\Psi_0^*+\Psi_0\Psi_r^*+\Psi_r\Psi_0^*. \tag{21}$$

We introduce the following notation for the third and fourth terms of (21):

$$\Psi_0\Psi_r^*=G, \tag{22}$$

$$\Psi_2\Psi_r^*=G^*. \tag{23}$$

Multiplying (22) by Ψ_r, we readily verify that the third term coincides with the point multiplication operator transforming the reference wave into the radiation wave scattered by the object.

We consider the interaction described by expression (21) between the radiation and the material model of traveling intensity waves. In this case, since we are not so much concerned with the actual properties of the hologram itself as with the properties of the optical field forming it, we disregard the effect of the detecting wave on the structure of the hologram, assuming instead that the recording and reconstruction processes are independent. With all of the foregoing in mind we assume that the reference-wave radiation Ψ_r (18) is incident on a three-dimensional medium whose dielectric constant is described by (21). In accordance with our stated assumptions the wave function Ψ_r must obey the wave equation

$$\left(\nabla^2-\frac{\varepsilon_0}{c^2}\frac{d^2}{dt^2}\right)\Psi_r=0, \tag{24}$$

where ε_0 is the distribution function for the dielectric constant prior to recording of the intensity waves.

Under the action of the intensity wave the dielectric constant acquires the increment $\delta\varepsilon$ (21). It is clear that the wave function experiences a corresponding change. We represent the resultant wave function as the wave function Ψ_r of the unperturbed problem plus a small addition due to the presence of $\delta\varepsilon$:

$$\Psi=\Psi_r+\Psi_f. \tag{25}$$

The perturbed part of the wave function is the required wave function for the radiation reconstructed by the hologram. Substituting the value of ε from (21) and the value of Ψ from (25), neglecting second-order small terms, taking account of (24), and differentiating Ψ_r twice with respect to time, we obtain

$$\left(\nabla^2-\frac{\varepsilon_0}{c^2}\frac{d^2}{dt^2}\right)\Psi_f=-\frac{\delta\varepsilon}{c}\omega_r^2\Psi_r. \tag{26}$$

The solution of the inhomogeneous equation (26) has the following well-known form:

$$\Psi_f=-\frac{\omega_r^2}{4\pi c}\int\limits_{V\left(t-\frac{r}{c}\right)}\frac{\delta\varepsilon\Psi_r}{r}\,dV. \tag{27}$$

Here the index V(t − r/c) attached to the integral signifies that the integration is carried out over the volume V of the hologram and that the integrand, accordingly, is evaluated with a delay to account for the propagation time of the light to the point of observation. As in the case of recording of a standing wave, the third term of (21) is responsible for the formation of the image. Accordingly, replacing $\delta\varepsilon$ in (27) by the value of G from (22), we obtain

$$\Psi_f = -\frac{\omega_r^2 a_r^2}{4\pi c} \int\limits_{r\left(t-\frac{r}{c}\right)} \frac{\Psi_0}{2}\, dV, \tag{28}$$

where a_r is the amplitude of the reference wave.

Substituting into (28) the value of Ψ_0 from (19) with its time factor omitted, we rewrite this expression in the form

$$\Psi_f = -\frac{\omega_r^2 a_r^2}{4\pi c} e^{i\omega_0 t} \int\limits_V \frac{\psi_0(r)\, e^{ik_0 r}}{r}\, dV. \tag{29}$$

Expressions with similar integrals have been interpreted previously[1,3] as wave functions generated by the wave function in the integrand. Using this interpretation, we conclude that the wave function for the radiation reconstructed by the model of traveling intensity waves coincides with the wave function for the object-scattered radiation, correct to the effects indicated in refs. 1 and 3.

It is interesting to note that the behavior of the pseudoscopic image in the case analyzed here differs significantly from that encountered in the recording of standing waves. Thus, suppose that a counterwave Ψ_r' opposing the reference wave Ψ_r involved in the formation of the hologram is incident on the model of traveling intensity waves. Modifying expression (18), we write the wave function for this counterwave as follows:

$$\Psi_r' = \psi_r^*(r)\, e^{i\omega t}. \tag{30}$$

Replacing Ψ_r in (27) by the value of Ψ_r' from (30) and replacing $\delta\varepsilon$ by the value of G^* from (23) [the fourth term of (21) corresponds to the pseudoscopic image], we find the wave function for the radiation reflected by the model in this case:

$$\Psi_f' = -\frac{\omega_r^2 a_r^2}{4\pi c} e^{i(2\omega_r - \omega_0)t} \int\limits_V \frac{\Psi_0^*(r)\, e^{i(2k_r - k_0)r}\, dV}{r}. \tag{31}$$

It follows from (31) that the pseudoscopic image in the given case has a frequency shift due to the Doppler effect and is therefore somewhat distorted, because the integrand of (31) has a different form from the corresponding Kirchhoff equation.

We have thus shown that a spatial pattern of traveling intensity waves also has the potential capability for reconstruction of the wave field of an object. Moreover, in addition to other parameters of the wave field, the frequency shift of the spatial wave relative to the reference wave is also reproduced, indicating that the imaging properties of the spatial pattern of traveling intensity waves have an even more general character than the corresponding properties of a standing wave pattern. Also typical from this point of view is the fact that the pseudoscopic image in the case of traveling waves tends to break down while the true image is simultaneously preserved, i.e., the optical properties of the traveling wave model tend to approximate even closely the optical properties of the object, which, of course, does not form any pseudoscopic images.

The effect be exhibited directly in the majority of cases in the form represented here; when the medium reacts to the light at the instant of its inception, the detecting wave itself influences the structure of the traveling wave model, and this fact is disregarded in the present analysis. It is to be expected, however, that this and other related possible effects will affect only the details of the process without changing its basic properties.

The imaging of the properties of an object by a pattern of traveling intensity waves can be used for the design of diverse radiation converters in situations, among others, where it is required to vary the wavelength. It should also find applications in real-time data-processing devices, in particular for the formation of optical images in the recording of objects by means of acoustic and rf electromagnetic waves.

Extrapolation of the Langmuir S-curve to cesium pressures of 10-100 torr

V. E. Dubinskii and S. Ya. Lebedev

(Submitted February 15, 1973)
Zh. Tekh. Fiz., 44, 138-141 (January 1974)

The thermionic current is plotted as a function of the temperature for titanium, niobium, tantalum, molybdenum, tungsten, nickel, rhenium, carbon, and type 1Kh18N9T steel in cesium vapor at pressures from 10^{-6} to 10-100 torr by an extrapolation of experimental data.

The thermionic current cannot be studied experimentally as a function of the sample temperature (the Langmuir S curve cannot be recorded) at cesium vapor pressures above 10^{-3} torr because a discharge occurs in the experimental apparatus. We have therefore extrapolated the experimental results reported previously[1] to cesium vapor pressures of 10-100 torr. The curves were calculated in 1963 and used for working purposes, but the pressures in the data on most of these elements and on type 1Kh18N9T (Soviet designation) stainless steel are now three orders of magnitude lower.[2] The extrapolation is carried out for those parts of the curves corresponding to the lowest surface coverage by cesium at the minimum work function.

EXTRAPOLATION METHOD

We illustrate the extrapolation method for titanium. Figure 1a shows the experimental and extrapolated values of log (j/T^2) as functions of the reciprocal temperature (1000/T) superimposed on a grid of lines of constant work function (φ = 1.42–3.95 V). Also in this figure are lines of constant work function plotted as log μ_a (the ordinate) vs 1000/T (the abscissa); here, j is the current density and μ_a is the atomic flux $(\mathrm{cm}^{-2}\cdot\mathrm{sec}^{-1})$.

The values of log μ_a are related to the pressure p (torr) and the temperature of the cesium vapor T (°K) by the familiar relation

$$\lg \mu_a = \lg p - \frac{1}{2}\lg T_a + 21.4843, \tag{1}$$

and the values of log p as a function of the temperature are taken from ref. 3:

$$\lg p = 10.5460 - 1.00 T_a - \frac{4500}{T_a} \tag{2}$$

for temperatures T_a below the melting point of cesium (302°K) or

$$\lg p = 11.0531 - 1.35 \lg T_a - \frac{4041}{T_a} \tag{3}$$

for $T_a > 302$°K.

Accordingly, by substituting log p from (2) and (3) into (1), we find log μ_a as a function of the temperature alone:

$$\lg \mu_a = 32.0303 - 1.5 \lg T_a - \frac{4150}{T_a} \quad (T_a < 302\,^\circ\mathrm{K}),$$

$$\lg \mu_a = 32.5374 - 1.85 \lg T_a - \frac{4041}{T_a} \quad (T_a > 302\,^\circ\mathrm{K}).$$

The lines of constant work function plotted in the coordinates $10^3/T$ and $\log(j/T^2)$ by the "total-current method" are straight lines $[\log(j/T^2) = \log A_0 - 2.30(e\varphi)/(kT)$, where $A_0 = 120\ \mathrm{A/cm^2\cdot deg\,K}]$. Clearly, this representation of the lines of constant work function as straight lines in terms of the coordinates 1000/T and log j (ref. 4) is frequently not correct.

The quantity log μ_a can be written as a function of the pressure. Such functions are shown in the upper part of the figure; the ordinate at the right shows log μ_a, and that at the left shows the pressure.

The S-curves are curves for constant values of the vapor temperature, the vapor pressure, and the flux μ_a. The intersections of each experimental curve with the series of lines of constant work function are displaced, at the same values on the abscissa, to the lines log μ_a = const(T_a) = const (p). According to Langmuir's "surface-phase" postulate, the values of log μ_a for a constant work function lie approximately on a straight line.[4,5] The lines of constant work function are drawn through these displaced experimental points in such a way that the slopes and spacings vary smoothly. Then these lines intersect the horizontal lines log μ_a = n, where n = 14, 15, 16, ..., 22.

In this manner the range of μ_a and, correspondingly, the pressure are increased (from $\mu_a = 10^{14}$ to $\mu_a = 10^{22}$ $\mathrm{cm}^{-2}\cdot\mathrm{sec}^{-1}$ and p = $0.54\cdot10^{-6}$–91 torr).

Then the opposite displacement is carried out: The intersections of the lines log μ_a = n with lines of constant work function are displaced (with the same abscissa) to the corresponding lines of constant work function in the coordinates 1000/T and log j/T^2. The resulting points, which correspond to the same value of μ_a, are joined by a curve. For low coverages this curve (dashed curve) is continued to the line for the work function of the element without cesium,[6] like the curves for tungsten in ref. 4.

Figure 1, b-i, shows the extrapolated curves for niobium, tantalum, molybdenum, tungsten, carbon, nickel, rhenium, and type 1Kh18N9T stainless steel.

To assist in the use of these curves we note that log j is found from data plotted from

$$\lg j = \lg \frac{j}{T^2} - 2\lg\left(\frac{1000}{T}\right) + 6.$$

These extrapolated curves differ from those reported in refs. 2-4 for the respective elements, apparently because of discrepancies in the original experimental data.

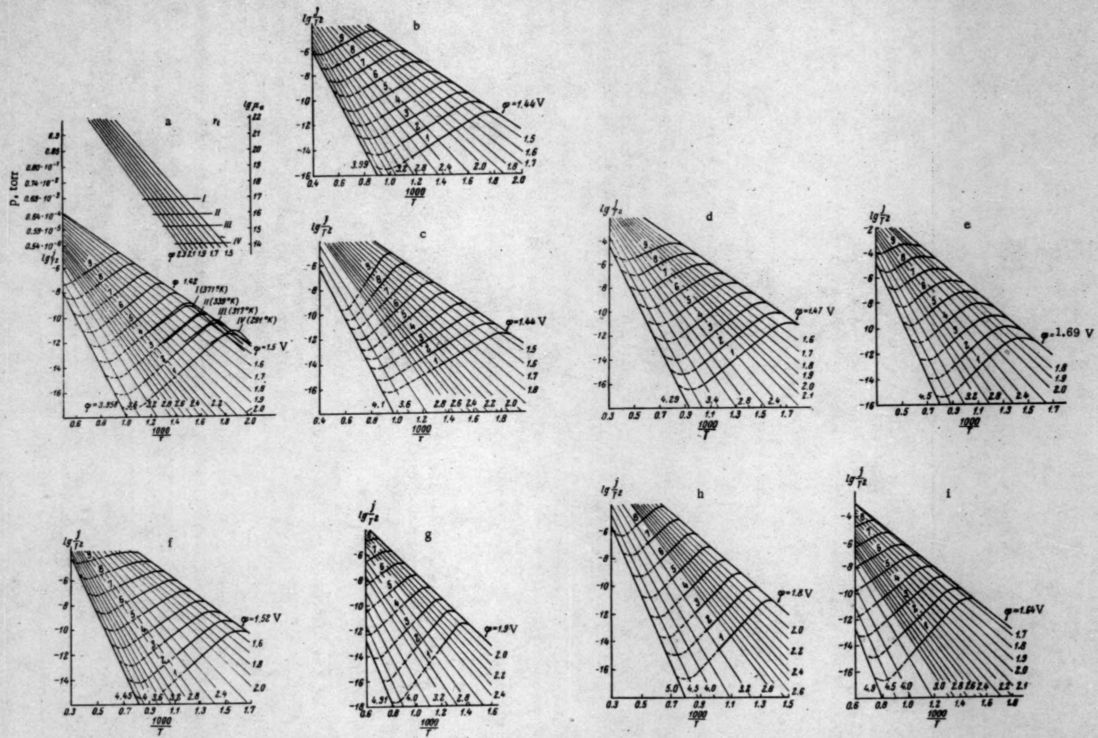

Fig. 1. The quantity j/T^2 as a function of the reciprocal cathode temperature for titanium (a) for various cesium vapor temperatures (T_a), and for niobium (b), tantalum (c), molybdenum (d), tungsten (e), carbon (f), nickel (g), rhenium (h), and type 1Kh18N9T stainless steel (i). T_a, °K: 1) 290; 2) 313; 3) 340; 4) 375; 5) 419; 6) 472; 7) 542; 8) 642; 9) 778 and 772 (Ti, Ta, W). n: 1) 14; 2) 15; 3) 16; 3) 17; 5) 18; 6) 19; 7) 20; 8) 21; 9) 22. In Part a, curves I-IV are experimental.

Effect of crystal structure on certain angular dependences of the ion–electron-emission yield

B. A. Brusilovskii and V. A. Molchanov

M. V. Lomonosov Moscow State University

(Submitted December 15, 1972; resubmitted June 18, 1973)
Zh. Tekh. Fiz., 44, 142-147 (January 1974)

An experimental study is made of the angular dependences of the ion–electron-emission yield of a metal single crystal as the ion beam is displaced along crystallographic planes with different atomic-packing densities. The targets are molybdenum and copper crystals. These are bombarded by 30-keV argon ions. Under these conditions, when the ion beam moves along a plane with a high atomic density the half-width of the minimum corresponding to a close-packed crystallographic direction assumes its minimum value. The width of the maximum, measured at a fixed emission yield, assumes its maximum value under these conditions. The results are discussed qualitatively on the basis of the theory for crystal transparency.

When a solid surface is bombarded by intermediate-energy ions, intense electron emission is observed.[1] When the target is a single crystal, the angular dependences of the ion–electron-emission yield γ are nonmonotonic. In particular, study of the electron emission from the (100) face of a copper crystal shows a correlation between the minima of the angular dependences with directions in which the crystal lattice is most transparent. The shape, depth, and width of these minima yield information about the influence of the ordered atomic arrangement on electron emission from the crystal. These quantities have been studied as functions of the nature and energy of the incident ions, the distance between the atoms in the given crystallographic direction, the target temperature, etc.[1-6] However, the information which has been obtained on these properties as functions of the incidence angle of the ions and the azimuthal angle does not provide an adequate basis for reaching a complete understanding of the effect of the ordered structure on the emission. Study of the shape, depth, and width of the minima as functions of various factors can therefore yield information useful for reaching an understanding of the mechanism for electron emission in ion bombardment.

We report here on an experimental study of the shape and width of the minima corresponding to close-packed directions as functions of the azimuthal angle and the angle at which the ions are incident on the target.

The measurements are carried out by the standard procedure described elsewhere.[4] Singly charged 30-keV argon ions are used at a current density of ~ 2 mA/cm². The targets are the (110) and (111) faces of a molybdenum crystal and the (110) face of a copper crystal. The target can be rotated around two orthogonal axes. One axis lies in the plane of the target surface. The angular position around this axis, φ, is measured from the normal to the surface. The other axis is normal to the surface. The angular position around it, β, is measured from the ⟨112⟩ direction. The angles φ and β are measured within 1°.

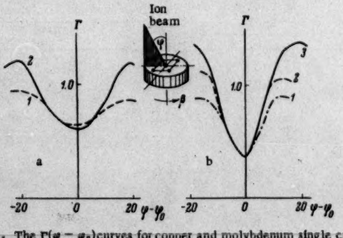

Fig. 1. The $\Gamma(\varphi - \varphi_0)$curves for copper and molybdenum single crystals.

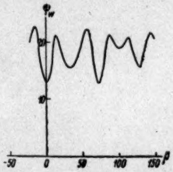

Fig. 2. The $\phi_W(\beta)$ curve for the <110> minimum of a copper crystal.

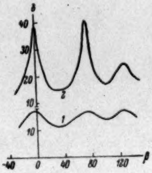

Fig. 3. The $\delta(\beta)$ curve for the <110> minimum of a copper crystal.

The ion–electron-emission yield γ is measured as a function of the angle at which the ions are incident on the target, φ, for a fixed angle β, or γ is measured as a function of β at fixed φ. The total increase in the yield γ for a metal crystal observed with an increase in the angle of incidence is known to be of approximately the same nature as the increase in the corresponding yield for a polycrystalline material, γ_p. Accordingly, to eliminate the influence of this common increase in a comparison of the yields, we compare values of the reduced yield Γ, defined by

$$\Gamma = \frac{\gamma}{\gamma_p}.$$

The value of γ_p is taken from ref. 7.

We turn first to the curves obtained at a fixed azimuthal angle β. Figure 1 shows parts of the $\Gamma(\varphi)$ curves corresponding to the ⟨111⟩ directions of a molybdenum crystal (Fig. 1a) and the ⟨110⟩ directions of a copper crystal (Fig. 1b). Here, the ordinate shows $(\varphi - \varphi_0)$ (φ_0 is the angle at which the incidence direction of the ions coincides

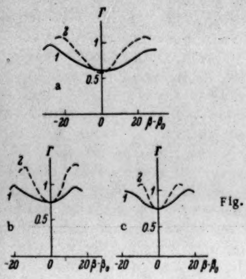

Fig. 4. The $\Gamma(\beta-\beta_0)$ curve for a molybdenum crystal.

with the corresponding crystallographic directions). Curves 1 and 2 in Fig. 1a are obtained by rotating the crystal around the ⟨110⟩ and ⟨123⟩ axes, and curves 1-3 in Fig. 1b are obtained by rotating it around the ⟨111⟩, ⟨100⟩ and ⟨115⟩ axes. We select these axes because the beam moves along planes differing in packing density. We see from this figure that for a given crystallographic direction the values of β, i.e., obtained by rotating the target around various axes, are approximately the same only at small values of $|\varphi-\varphi_0|$. It also follows from this figure that the minima observed as the beam moves along a close-packed plane have smaller depths and half-widths than the minima observed when the beam moves along a plane with a low density of atoms. The width measured at some arbitrarily chosen value Γ = const, on the other hand, is larger for the minimum obtained with the beam moving along a close-packed plane.

Figure 2 shows, as a function of the azimuthal angle β, the half-width of the ⟨110⟩ minimum of a copper crystal. We see that the half-width is a nonmonotonic function of β. The curve displays minima at β = 0, 35, 70, 100, and 126°. It follows from a stereographic projection of the (110) face that at these angles the plane of incidence of the beam (the plane passing through the beam and the normal to the surface) coincides with the (111), (110), (111), (113), and (100), planes respectively. The deepest minima are those at 0 and 70°. It follows from the data in this figure that

$$\psi_w(0)\simeq\psi_w(70)<\psi_w(35)<\psi_w(126)<\psi_w(100).$$

Figure 3 shows the functional dependence of the angle β of the widths of the minima, δ, measured at certain fixed values Γ = const. We see that the width of a minimum at Γ = const represents the rate of increase of the ion–electron-emission yield with increasing φ. Curves 1 and 2 in this figure are obtained for two arbitrarily chosen values of Γ: 0.65 for the first and 0.8 for the second. In both cases there are maxima on the curves corresponding to coincidence of the incidence direction with the (111) and (100) close-packed planes. The maximum corresponding to the (111) plane is higher than that corresponding to the (100) plane and increases with the value of Γ at which the $\delta(\beta)$ curve is recorded.

We turn now to the $\Gamma(\beta)$ curves for a fixed angle φ for the molybdenum (110) and (111) faces. Figure 4 shows parts of the $\Gamma(\beta-\beta_0)$ curves corresponding to the ⟨111⟩ (Fig. 4a) close-packed direction, the ⟨110⟩ direction (Fig. 4b), and the ⟨113⟩ direction (Fig. 4c). In these figures β_0 is the angle at which the beam direction coincides with the crystallographic direction in question. Curves 1 in Fig. 4 are obtained at incidence angles φ of 35, 35, and 31.5°K, respectively, while curves 2 are obtained at 70, 60, and 65°. In each figure the values of Γ for curves 1 and 2 are approximately equal only at angles $(\beta-\beta_0)$ less than 3-4°; at all other angles, Γ is lower for curves 1, i.e., for the lower value of φ. The half-widths of the minima on the $\Gamma(\beta-\beta_0)$ curves for the lower values of φ are larger by a factor of 1.5-1.7 than the half-widths of the corresponding minima at the large value of φ. Accordingly, the shape and half-width of the minima corresponding to a given direction are functions of the angle of incidence φ.

Let us compare the shape and half-width of a minimum corresponding to a certain crystallographic direction for the case in which the target is rotated around the normal to the surface (φ = const) with the shape and half-width of the same minimum when the target is rotated around some axis in the target plane (β = const). Figure 5 shows $\Gamma(\beta-\beta_0)$ and $\Gamma(\varphi-\varphi_0)$ curves corresponding to the low-index ⟨111⟩ (Fig. 5a) and ⟨100⟩ (Fig. 5b) axes. Curves 1 are obtained by rotating the copper crystal around the normal to the surface, while curves 2 are obtained by rotating around the ⟨110⟩ axis (Fig. 5a) or the ⟨100⟩ axis (Fig. 5b), both of which are in the plane of the target surface. In both cases the half-widths of the minima observed in the rotation around β are larger than those of the minima observed in the rotation around φ. It follows from these results that the shape and width of the minima on the $\Gamma(\varphi-\varphi_0)$ curves obtained at a fixed value of β are functions of this angle, while the shape and width of the minima on the $\Gamma(\beta-\beta_0)$ curves recorded at fixed φ are functions of φ.

We turn now to a qualitative discussion of these results. The minima corresponding to close-packed directions are formed because the surface atom shadows all atoms lying below it along the given direction.[8,9] If the beam is incident along a close-packed direction, an increase in the angle between the beam direction and the crystallographic direction under consideration, ψ_S, allows the interior atoms to emerge from the shadow and leads to an increase in Γ. For the $\Gamma(\varphi)$ curves the angle ψ_S would be $\varphi-\varphi_0$. As the beam is moved along a plane with a low packing density, ψ_S continues to increase with increasing ψ_S until all the atoms emerge from the shadow. As the beam is moved along a close-packed plane, there can apparently be situations in which atoms of lower layers, without completely emerging from the shadow of one atom, enter the shadow of a different atom, belonging to a neighboring row, at some angle ψ_S. As a result, the rate at which Γ increases with increasing ψ_S is lower than that

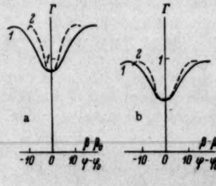

Fig. 5. The $\Gamma(\beta-\beta_0)$ and $\Gamma(\varphi-\varphi_0)$ curves for a copper crystal.

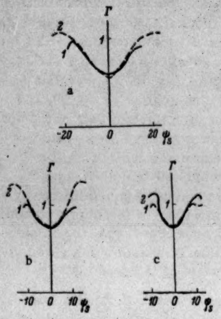

Fig. 6. The $\Gamma(\psi_s)$ curve for a molybdenum crystal.

in the case in which the beam moves along a plane with a low atomic density. With a further increase in ψ_s, the shadows of the atoms in the upper rows can begin to overlap, leading to further shadowing of the interior atoms. On the closest-packed planes, the shadow may become so pronounced at some value ψ_s that a further change in ψ_s has little effect on the effectiveness of the shadow, and the value of Γ should change a little. With a further increase in ψ_s the incidence direction of the beam approaches another close-packed direction, and Γ begins to decrease. Obviously, the higher the density of the atomic packing in the planes, the more pronounced the shadowing can become. It thus follows that the rate of increase of the $\Gamma(\psi_s)$ curve with increasing ψ_s depends on the plane along which the beam is moving, i.e., on the angle β. As a result, the width of the minimum, δ, is also a function of β; the functional dependence $\delta(\beta)$ must have a maximum where the incidence direction of the beam is parallel to a close-packed plane, and the maxima corresponding to the more closely packed planes must be larger. It is precisely this type of functional dependence $\delta(\beta)$ which is observed experimentally (Fig. 3). It also follows that the maximum value of $\Gamma_{\max}$, reached when the beam moves along a close-packed plane, is smaller than the maximum reached during motion along a loosely packed plane. This circumstance could lead to a decrease in the half-width of the minimum on the $\Gamma(\varphi-\varphi_0)$ curve obtained when the target is rotated around the axis perpendicular to a close-packed plane. According to our experiments (Fig. 2) the minima on the $\psi_W(\beta)$ curve are in fact observed when the beam moves along a close-packed plane. Since the atomic density in the planes in an fcc crystal falls off in the order (111), (100), (110), (113), the depth and half-width of the minima should apparently also fall off in the same order. However, this order is not completely reproduced experimentally. For example, the half-width of the minimum at β = 35° is larger than that of the minimum at β = 0, i.e., larger than the half-width of the minimum corresponding to the closest-packed plane; and the minimum at β = 35° is deeper than that of β = 126°. Accordingly, the appearance of a minimum at β = 35° may be partially or completely due to the overlap of neighboring minima, rather than to the effect of the ordered arrangement of atoms in the planes. The same can apparently be said regarding the minimum at β = 100°.

We turn now to Fig. 4, from which we see that the shape and half-width of the minima on the $\Gamma(\beta-\beta_0)$ curves corresponding to close-packed directions and a certain fixed value of φ differ from those obtained for the same direction but a different fixed value of φ. One possible cause of this behavior could be a functional dependence of ψ_s on β and φ. On the other hand, as in the case of the $\Gamma(\varphi)$ curves, this difference could be due to the effect of the ordered arrangement of atoms in planes forming the given direction. Here, however, account must be taken of the circumstance that, in contrast with rotation around φ, the angle between the plane along which the beam moves and some close-packed plane is not constant during the rotation around β; this circumstance can affect the shape and half-width of the minimum under consideration. It follows from the geometry of the problem that the angle between the incidence direction and the crystallographic direction, ψ_s, can be written as

$$\cos\psi_s = \cos\varphi\cos\varphi_1 + \sin\varphi\sin\varphi_1\cos(\beta-\beta_0),$$

where φ_1 is the angle between the given crystallographic direction and the normal to the target surface, and $\beta-\beta_0$ is the angle formed by the plane containing the normal to the target surface and the given direction with the plane of incidence of the beam. The $\Gamma(\beta-\beta_0)$ curves shown in Fig. 4 are converted into $\Gamma(\psi_s)$ curves on the basis of this equation; the results are shown in Fig. 6. Here the shapes of the minima obtained at different values of φ and small values of ψ_s agree well, i.e., the difference between the shapes of these minima on the $\Gamma(\beta-\beta_0)$ curves at small $\beta-\beta_0$ can in fact be attributed to a functional dependence of ψ_s on φ, φ_1 and β. At larger values of ψ_s, however, there is a difference between the shapes of minima 1 and 2 on the $\Gamma(\psi_s)$ curves. As in the case of the $\Gamma(\varphi)$ curves, this difference is apparently due to a sensitivity of the emission to the ordered arrangement of atoms in the planes; in certain cases it could also be due to an overlap of the given minimum with the minimum corresponding to the neighboring crystallographic direction. As in the previous case, the differences between the shapes and half-widths of the minima observed when the target is rotated around the axis perpendicular to the plane of the target surface and the corresponding properties of the minima corresponding to the same directions but observed when the target is rotated around an axis lying in this plane can apparently be attributed to a functional dependence of the half-width of the minimum on the angles φ, φ_1, and β and to the sensitivity of the emission to the ordered arrangement of atoms in the close-packed planes (Fig. 5).

We have thus shown that the $\psi_W(\beta)$ and $\delta(\beta)$ curves are nonmonotonic and that the shapes and half-widths of the minima on the $\Gamma(\varphi-\varphi_0)$ and $\Gamma(\beta-\beta_0)$ curves are functions of the angles β and φ, respectively. The experimental results have been discussed qualitatively on the basis of existing ideas regarding the mechanism for ion–electron emission.

In conclusion the authors thank A. V. Smirnov for assistance in this work and Z. K. Zolina for help in orienting the single crystals.

Perveance of a vacuum with a point cathode

S. P. Bugaev, E. A. Litvinov, V. V. Lopatin, and G. A. Mesyats
Institute of Atmospheric Optics, Siberian Branch,
Academy of Sciences of the USSR, Tomsk

(Submitted July 17, 1972)
Zh. Tekh. Fiz., 44, 148-152 (January 1974)

The voltage–current characteristics have been obtained for vacuum diodes with point cathodes operating under conditions of explosive electron emission. A difference is found between the oscillograms of the electron current at small (~50 kV) and large (~300 kV) amplitudes of the voltage pulses. The electron current is shown to be space-charge-limited. The electron current is using the x radiation produced by stopping the beam in a metal foil. There is a difference at low and high voltages: At low voltages the current-density distribution over the beam cross section is Gaussian; at high voltages the beam has an annular cross section.

Point cathodes operating under conditions of explosive emission of electrons are frequently used in the diodes of nanosecond pulsed electron accelerators and x-ray apparatus.[1] The appearance of the discharge current in the evacuated gap of such a diode during electrical breakdown coincides with the appearance of a plasmoid at the cathode (a cathode burst[2]), which expands at $v = 2 \cdot 10^6$ cm/sec. The current through the diode under these conditions is limited by the space charge ("3/2" law).[1,3]

We report here on a study of the current-carrying capability of a diode with a point cathode; the electron-beam has also been studied. The diode has a single-point cathode and a plane anode, separated by a vacuum gap of width d. When a voltage pulse is applied to the cathode, the plasma of the cathode burst appears (Fig. 1). The experiments are carried out under conditions such that the burst appears for times not exceeding 10^{-9} sec.

The perveance $p = iu^{-3/2}$ is found as a function of the ratio $vt/(d - vt)$ (where i is the current and u is the voltage drop across the diode) with $5 \cdot 10^{-12}$ cm $\leq d \leq 6 \cdot 10^{-1}$ cm and at voltages $10^4 \leq u_0 \leq 1.6 \cdot 10^5$ V in refs. 1,3. The experimental points are shown in Fig. 1. Examination of this figure shows that the current through the diode is limited by the space charge of electrons in the gap.

When the electric field at the point is higher than the fields in refs. 1,3, the current behavior is different. Figure 2 shows oscillograms of the diode voltage and current, x-ray patterns of the electron beam at the anode and histograms of the beam density for a given point at 75 and 300 kV. In the first case the current pulse is triangular, in the second it is trapezoidal with a sharp rising part. The perveance p for high values of u is shown in Fig. 1. The beam structure is studied by detecting the bremsstrahlung from the anode, which is a disk of tantalum foil 150 μ thick; a piece of photographic film is pressed tightly against the back side of the foil. The beam structure also changes with increasing u, becoming annular with a central core.

To calculate p we must solve the nonlinear partial differential equations describing the motion of the charged particles, taking into account the space charge of these particles. This is a very difficult task. Ivey[4] described certain approximate methods used to calculate the electric current through complex diodes. The most versatile method is that of Matricon and Trouve,[5] which is based on the total capacitances of different configuration. In these calculations the specific capacitances are equated. We write the solution of the Poisson equation, taking account of the space charge and the nonvanishing field at the cathode for the case of a plane diode:

$$\left(\frac{4\pi j}{\sqrt{2\frac{e}{m}}}\right)^2 d^2 - \frac{E^3 d}{3} + \frac{uE^2}{3} - \frac{4u^{3/2}}{9}\left(\frac{4\pi j}{\sqrt{2\frac{e}{m}}}\right) = 0. \qquad (1)$$

If the current density j is set equal to zero, Eq. (1) corresponds to the electrostatic case without space charge: $E = -u/d$. If $E = 0$, the cathode is completely shielded by space charge: $j = (\sqrt{2(e/m)}/9\pi)(u^{3/2}/d^2)$. Intermediate cases are described by Eq. (1). If we find the field for an arbitrary configuration and equate it to the field of a plane capacitor, we can find the effective gap width d_{eff}; substituting this into the "3/2" equation for the planar diode, we find the current density. A similar approach has been used by Dyke and Trolan[6] in a study of the effect of space charge on field emission. The total current can be found by integrating over the emitting surface. For this case the distribution of the potential φ can be written as[7]

$$\left.\begin{aligned} &\varphi = \frac{u}{(d - vt)^{\nu}}\left[r^{\nu} - (vt)^{2\nu+1} r^{-\nu-1}\right] P_{\nu}(\cos\theta), \\ &0 \leqslant \nu \leqslant 1, \quad P_{\nu}(\cos\alpha) = 0, \quad \alpha > \frac{\pi}{2}, \end{aligned}\right\} \qquad (2)$$

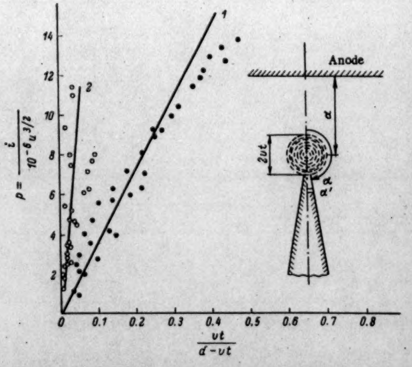

Fig. 1. Perveance of a diode with a point cathode as a function of the normalized time vt/(d − vt). Here v is the plasma-expansion velocity, d is the width of the gap, and t is the time. The voltage u is: 1) ≤ 50, 2) ≥ 200 kV.

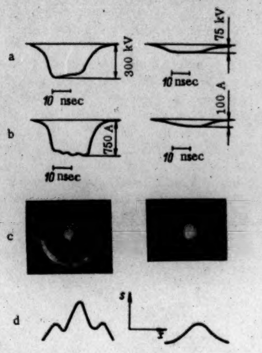

Fig. 2. a) Oscillograms of the voltage across a diode with a point cathode; b) current oscillograms; c) x-ray patterns of the electron beam; d) histograms of the current density.

where $P_\nu(x)$ is a Legendre function and r and θ are spherical coordinates; then

$$d_{\text{eff}}^{-1} = \left(\frac{vt}{d-vt}\right)^{\nu} (vt)^{-1} (2\nu+1) P_\nu(\cos\theta)$$

and

$$i = 2.33 \cdot 10^{-6} u^{3/2} \left(\frac{vt}{d-vt}\right)^{2\nu} (2\nu+1)^2 \int d\Omega p_\nu^2(\cos\theta). \qquad (3)$$

Since it is ussually true that $\alpha \simeq 160°\text{-}170°$, we find[8] $\nu \simeq 0.5$. The integration in (3) can be carried out over the solid angle subtended by the anode at the center of the cathode burst ($\Omega \simeq 2\pi$) or over the entire free surface of the plasma [$\Omega \simeq 2\pi(1-\cos\alpha)$]. There is an uncertainty here because we do not know the relative number of electrons that reach the collector. If we set the coefficient in (3) equal to the arithmetic mean of the numbers obtained in the specified integration range, we find

$$i = 37 \cdot 10^{-6} u^{3/2} \frac{vt}{d-vt}. \qquad (4)$$

Line 1 in Fig. 1 shows the perveance p as a function of the ratio vt/(d − vt) according to (4). Experimental points from ref. 3 are also shown; we believe the agreement is good.

We attribute the faster increase in the diode current at high voltages to the appearance of plasma from the lateral surface of the point, resulting from the explosion of microscopic protuberances there. To estimate the distance r_1 from the end of the point at which these explosions can occur, we use (2), finding, for $r_1 \gg vt$,

$$r_1 = \frac{2u^2\beta^2}{(d-vt)E^2\pi^2(1+\cos\alpha)}. \qquad (5)$$

where E is the local field at the lateral surface, and β is the amplification of the electric field, which takes into account the presence of microscopic roughness. For the plasma to appear during the rise time of the pulse, $t_r \simeq 5$ nsec, we would have to have[9] $E \approx 10^8$ V/cm. In the experiments described above, the pertinent values are u = 300 kV, d = 1 cm, $\alpha \simeq 165°$, and $r_1 \simeq 0.1$ cm, so we find $\beta \simeq 50$. Since $r_1 \gg vt$ (in our case, $vt \simeq 10^{-2}$ cm), the result would be an increase in the electron current more rapid than that in ref. 3. This effect has been erroneously attributed to an increase in the expansion velocity of the plasma burst, v. To estimate the perveance, we use the method of equating specific capacitances, described above. For $r_1 \gg vt$,

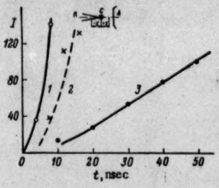

Fig. 3. Increase in the glow intensity I as a function of the elapsed time following the application of the voltage pulse. r, mm: 1) 0; 2) −0.5; 3) +0.5.

$$p = \left\{37\frac{vt}{d-vt} + 3\frac{r_1\left[\operatorname{tg}(\pi-\alpha') + \frac{vt}{r_1}\right]}{[1+\cos(\pi-\alpha')](d-vt)}\right\} \cdot 10^{-6}. \qquad (6)$$

The first term in (6) corresponds to emission from the cathode burst formed during the explosion of the end of the point, and the second corresponds to emission from the lateral surface when the plasma forms there as a result of the explosion of microscopic protuberances. Estimates for, e.g., $t = 1.2 \cdot 10^{-8}$ sec, d = 1.25 cm, and $u = 2.4 \cdot 10^5$ V lead to an experimental perveance of $\sim 3 \cdot 10^{-6}$ perv, while the theoretical value, determined from Eq. (6), is $\sim 4 \cdot 10^{-6}$ perv. Accordingly, the rapid current increase at the leading edge of the pulse (Fig. 2) can be attributed to explosive emission from the plasma formed at the lateral surface of the emitter. This conclusion is supported by the glow observed at the lateral surface of a point cathode during the first few nanoseconds after the application of the voltage pulse. A narrow optical slit was used in ref. 11 to time the appearance of the glow at certain distances from the end of the tip (Fig. 3); the results found there show that the area of the lateral surface covered by the glow increases with increase amplitude of the voltage across the diode. This effect cannot be attributed to expansion of the plasma, for the glow in the gap appears much later than that at the lateral surface of the tip.

At large values of u the concept of a perveance is slightly arbitrary, since the "3/2" law does not hold, because the area of the lateral surface over which the plasma can appear is a function of the voltage u.

We turn now to the reason for the annular structure of the electron beam. Electrons emitted from the lateral surface move in an electric field E and a magnetic field H, due to the current flowing through the emitter. This situation can be thought of approximately as roughly similar to the motion of a charged particle in orthogonal E and B fields. The circular magnetic field of the current deflects the electrons toward the cathode. The electron trajectories for a similar case were calculated in ref. 12; they turn out to be such that the beam can acquire a hollow structure. The effect is small if $(e\mu_0 H/m)t \ll 1$, where t is the transit time[13] and

$$\varphi = \frac{\left(\frac{e}{m}\right) j^2}{\varepsilon_0^2} \frac{t^4}{8}.$$

Setting $H \simeq 2i/4\pi y$ and $y \simeq r_1 \sin(\pi - \alpha')$, we find

$$t \ll \frac{2\pi r_1 \sin(\pi - \alpha') m}{e\mu_0} \left[\frac{ej}{6\varepsilon_0 m r_1 \sin(\pi - \alpha')} \right]^{1/3}. \tag{7}$$

Equation (7) is written in units of the International System. The current density j can be calculated on the basis of the effective gap width d_{eff}. Estimates for the experiments mentioned above yield $i \ll 10^3$ A, completely consistent with the observed behavior. Finally, the axial maximum of the current density in the electron beam can be attributed to the combined effects of the self magnetic field of the beam and of the ions entrained by the beam. The pinching of an electron beam during capture of ions from a plasma was described in refs. 14. This effect is usually accompanied by an anomalous acceleration of ions toward the anode[14] and occurs primarily in the axial part of the beam.

Production of collimated beams of high-energy electrons

V. I. Nemchenko

(Submitted January 14, 1972; resubmitted February 12, 1973)
Zh. Tekh. Fiz., 44, 153-163 (January 1974)

A study has been made of the properties of an extended, hindered discharge between plane electrodes at low pressure (0.26-0.047 torr) at voltages up to 15-20 kV. When the mean free paths of the charged particles are comparable to the characteristic dimension of the bounding insulator and interelectrode distance, the primary mechanism leading to an increase in the resistance of the hindered discharge and contraction at the axis is radial diffusion of charged particles from the active zone of the discharge. When the pressure is reduced to a critical value, and when the potential drop is increased to a critical value, the current is cut-off because of transverse loss. These critical values are functions of the diameter of the quartz insulator and the distance between electrodes. An arrangement of this kind can be used to produce collimated beams of high-energy electrons because of the high resistance of the discharge, the large potential drop (up to 15-20 kV), the high axial density, the high current density at the cathode spot, and the fact that most of the electrons are under essentially collisionless conditions.

Electron-beam diagnostics of flowing gases and plasmas is increasing in importance because of the accuracy and versatility of the method. The electron beams are usually produced by standard three-electrode guns with a hot cathode and magnetic or electrostatic beam focusing. This method suffers from the disadvantage that an independent vacuum system is required to produce a high vacuum $5 \cdot 10^{-5}$-10^{-6} mm in the beam region and in the aperture sections used for extracting the beam into the working chamber. This unnecessary complication of the apparatus reduces the usefulness of the beam for diagnostic purposes.

Plasma electron sources exploiting the properties of glow discharges may turn out to be useful for operation in evacuated aerodynamic tubes operating continuously in the slip and transient regimes. Methods for using plasma sources to produce electron beams have been developed rapidly in recent years. In particular, the plasma of a glow discharge between a hemispherical cathode and a plane anode at a pressure of 2-$5 \cdot 10^{-2}$ torr has been used to produce an electron beam and focus it onto a target.[1] In a slightly different arrangement, a glow discharge in an electrical-discharge tube with a lateral anode and magnetic focusing of electrons onto the target has been used at the same pressures.[1]

In several instances a discharge with a hollow cathode in the working chamber has been used to produce electron beams in welding and smelting.[2-5] It has been found that at certain pressures and voltages a discharge with a high ohmic resistance arises in the hollow cathode and an electron beam is emitted from the cathode. The beam can be highly focused because its space charge is neutralized by the ions. It is difficult to use an electron gun to study highly inhomogeneous jet flows or the flows which occur in hypersonic flow around a model because several discharge modes exist.

Dubinina and Ibadov[6] have described a hollow spherical cathode of a special design which can produce electrons with a high exit compression. A glow discharge is excited in the cathode cavity by an rf discharge. At an air pressure of the order of 1 torr the electron energy is about 0.2-0.3 keV. A disadvantage of the closed plasma electron source described above is the low electron energy – 2-3 keV at gas pressures from 5 to 0.02 torr; this energy is clearly too low for diagnostics of gas flows in the slip regime. Use of an electron gun for diagnostic purposes in gas dynamics is described, in particular, in ref. 7; unfortunately, no information is given there regarding the operating principle or design of the gun.

Examination of the basic properties of a glow discharge and the principles for producing collimated beams reveals that use of the cathode part of the discharge, at small interelectrode separations and low pressures (a "hindered" glow discharge[8,9]) holds some promise for producing a discharge with a high ohmic resistance and a high electron energy in a closed volume. Another way to produce a discharge with a high ohmic resistance would be to use the extended discharge which arises when the transverse dimensions of the discharge gas are limited.[8-10] Some study has been made of the effect of insulating limiting surfaces on the properties of discharges at high pressures (4-10 torr) in a large positive column.

In both cases the voltage across the discharge gap must be raised (above that required for an unlimited discharge) to compensate for the reduced cathode emission resulting from the reduction in the number of particles bombarding the cathode. A variety of factors lead to the loss of active particles. An extended discharge with a large positive column is essentially useless for producing high-energy electron beams. On the other hand, a hindered glow discharge cannot provide high discharge current densities because of the limited power level of the system; thus, this type of discharge cannot produce a sufficiently intense collimated electron beam. In the cathode part of the discharge the electrons, whose energy is governed by the cathode fall, undergo few collisions and escape along nearly linear trajectories normal to the surfaces of the electrodes. On the basis of these arguments we conclude that the most promising system for producing collimated beams of high-energy electrons is an extended hindered discharge in the cathode fall and in the adjacent part of the negative glow. The negative glow is important for producing a stable discharge.

We report here on an experimental study of a hindered glow discharge between plane electrodes in quartz tubes of various shapes and diameters at voltage drops up to 20 kV and at pressures from 0.26 to 0.047 torr. We describe the properties of the extended hindered glow discharge which develops under these conditions and certain properties of the collimated electron beam.

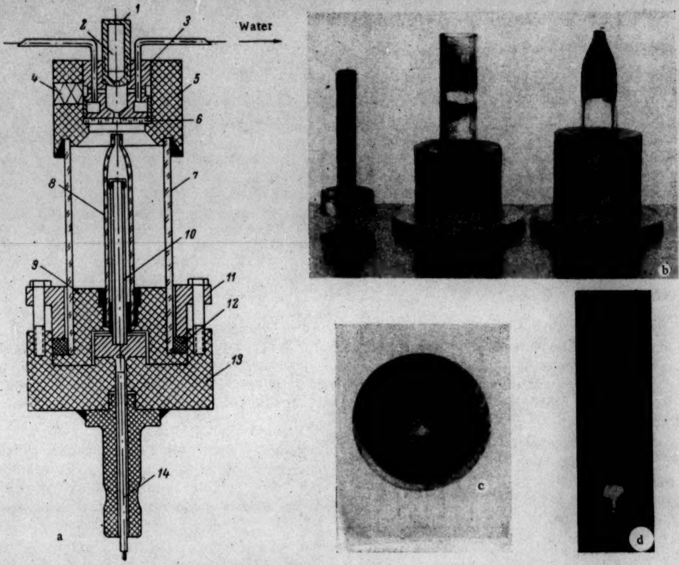

Fig. 1. Construction and certain characteristics of the discharge device. a) Construction of the discharge gap; b) cathodes with a flat end (1), a cylindrical quartz insulator (2), and a constricted quartz insulator (3); 3) surface of the end of the cathode, displaying erosion tracks; d) cathode region of the extended hindered discharge [1) Cathode; 2) quartz insulator; 3) contracted discharge column; 4) anode unit; 5) electron beam in working chamber].

Figure 1a shows the discharge gap used in these experiments. The cathode and anode units are connected by a glass mount 7. Stainless-steel anode 3 has an aperture 1.8 mm in diameter at its center and a cooling-water jacket. Limiting diaphragm 2 and quartz capillary 1 are screwed into the anode to increase the resistance of the gap between the cathode and the walls of the working chamber which is at the anode potential. The anode has a special recess and an aperture for communication between the inner volume of the discharge gap and the working chamber of the vacuum tube, through shielding metal grid 4. The cathode unit consists of the main body 13, high-voltage vacuum lead 14, insulating base 9, quartz insulator 8 (either 2 or 3 in Fig. 1b), and the cathode proper 10. The cathode with the flat end is made from stainless steel, clad in a quartz tube (1 in Fig. 1b). The cathode is 7 mm in diameter.

Power is supplied to the discharge gap from a supply with an NOM-2 transformer and a voltage doubler with D-1008 diodes. The primary circuit is regulated by a ferroresonant regulator. The output voltage is regulated by an autotransformer in the primary circuit. The discharge gap is connected through a ballast resistance of 1-3 kΩ in a positive-ground circuit.

The geometric parameters of the discharge gap which primarily determine the properties of the discharge in the specified pressure range are the interelectrode distance l and the diameter of the discharge tube, d. The interelectrode distance is chosen so that a small part of the negative glow is retained over the entire pressure range. At large values of the cathode fall V_k the product pL, which governs the size of the Faraday dark space at various pressures p, is a weak function of V_k. Under these conditions the data of ref. 8 can be used to estimate the appropriate electrode separation, which is then adjusted experimentally. In these experiments this distance is fixed at 25 mm. In connection with the diameter of the discharge tube, we note that the effect of limiting insulating surfaces on the characteristics of discharges has been described in the literature[8-10] for pressures on the order of 4-10 torr and at small voltage drops. Under these conditions the ratio E/p is comparatively small, and the mean free paths of the particles are small in comparison with the characteristic gap dimensions. However, collimated beams of high-energy electrons are more readily produced at large values of E/p [> 5-10 kV/(cm · torr)] and when the mean free paths of the particles are comparable to the characteristic gap dimensions. There is essentially no information on this case in the literature, so we have carried out special experiments to choose an appropriate diameter for the gas-discharge tube. All the results on the discharge characteristics are obtained by the standard glow-discharge techniques, involving processing of the electrodes at low pressures to the point at which the metal is sputtered.

Figure 2a shows the voltage–current characteristics of unlimited discharges in the evacuated chamber at pres-

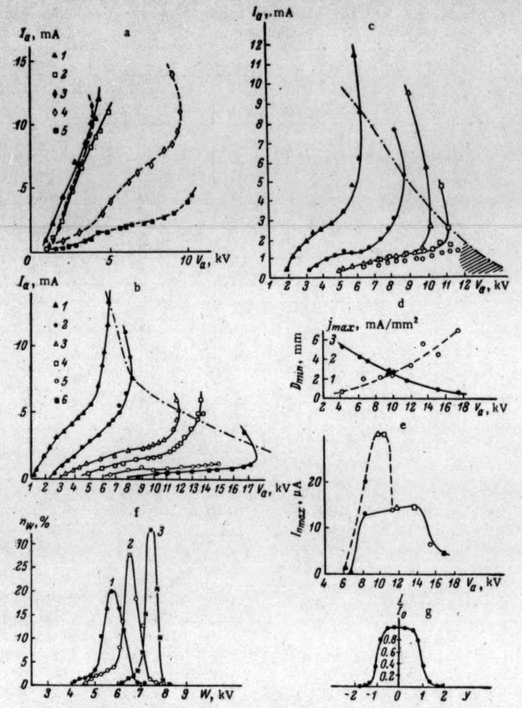

Fig. 2. Certain characteristics of the discharge as functions of the pressure for various configurations of the discharge gap. a: 1) Voltage–current characteristics of an unlimited discharge in the working chamber at a pressure of 0.21 torr; 2) the same, at 0.15 torr; 3-5) voltage–current characteristics of discharges at a pressure of 0.15 torr in cylindrical quartz insulators of various diameters [d, mm: 3) 33; 4) 14.5; 5) 10.2]. b: Voltage–current characteristics of discharges in cylindrical quartz insulators for various pressures in the working chamber. 1) p = 0.26 torr; 2) 0.15; 3) 0.105; 4) 0.084; 5) 0.068; 6) 0.057. c: Voltage–current characteristics of discharges in constricted quartz insulators at various pressures (the notation is the same as in Fig. 2b). d: Maximum current density (dashed curve) and minimum diameter of the cathode spot (solid curve) as functions of the voltage drop. e: Maximum electron-beam current for discharges in cylindrical insulators (solid curve) and in constricted insulators (dashed curve) as a function of V_a at various pressures (the same as in Fig. 2b). f: Electron energy distributions. 1) V_k = 6.0 kV; 2) 6.7; 3) 7.7 (p = 0.15 torr). g: Current distribution along a diameter of the electron beam for $V_a \approx$ 8 kV, p = 0.15 torr, and I_a = 7 mA.

sures of 0.21 torr (1) and 0.15 torr (2), along with those for discharges in cylindrical quartz tubes of various diameters at 0.15 torr. We see that the use of an insulating surface to limit the size of the discharge gap reduces the discharge current at a given voltage drop across the gap. As the supply voltage is raised to a certain limit, there is a transition from an increasing voltage–current characteristic to a decreasing one.$^{1)}$ As the tube diameter is reduced, the transition region shifts toward higher voltages, i.e., the discharge resistance increases. The change in the sign of the derivative of the characteristic can be attributed to two factors. First, the uncooled cathode is warmed because the intensity at which it is bombarded increases with increasing particle energy; this behavior is also observed in an unlimited discharge (1 and 2 in Fig. 2a). Second, there is a change in the pressure in the gap when the temperature increases and when cathode material is sputtered (and the evacuation rate is limited). The pressure change can be seen by comparing the characteristics for limited and unlimited discharges (1-3 in Fig. 2a). The characteristic for a limited discharge at the maximum tube diameter, at which the role of the insulating surface

in shaping the discharge is slight, and at low voltage drops (characteristic 3), coincides with that for an unlimited discharge at the same pressure (2); then, as the current and the voltage drop increase, there is a transition to the characteristic of the unlimited discharge at a higher pressure (1). In this apparatus an increase in the supply voltage thus increases the pressure.

Accordingly, steady-state characteristics can be obtained only if the supply voltage is held for a period of time at each higher value before the corresponding experimental point is recorded. During this period the values of p, V_a, I_a, and I_n reach a steady-state. If, instead, the supply voltage is increased rapidly, the discharge can jump irreversibly to the descending branch of the characteristic. Figure 2b shows discharge characteristics for various pressures in the working chamber for discharges in cylindrical quartz tubes having an inside diameter of 11.2 mm. Reducing the pressure in the chamber reduces the discharge current at a fixed voltage drop and shifts the extremum on the voltage – current characteristic toward higher voltages.

The experimental results (expecially the discharge characteristics for various tube diameters but at fixed values of l, p, and V_a) show the dominant role of diffusion, which leads to a rapid transverse loss of charged particles, in shaping the discharge.

A quantitative theory for transverse loss has been worked out for high pressures and low values of the ratio, E/p, for which the mean free paths of the particles are much smaller than the characteristic gap dimensions, and the particle energy distribution is Maxwellian or approximately so.[8,11] When E/p is large, the drift velocity of the charged particles is much higher than the thermal velocity, the mean free paths of the particles are comparable to the characteristic dimensions of the discharge, and the particle energies and energy distributions are non-Maxwellian and (generally) unknown. No reliable recommendations have been offered for calculating the transverse loss due to diffusion under such conditions.

From the results in Figs. 2a and 2b we see that under these experimental conditions the field E reaches nearly 10 kV/cm and that E/p can reach 140 kV/(cm · torr). At these values of E/p the mechanism governing the transverse loss would apparently be the scattering of particles in collisions and the resulting escape of charged particles from the active zone of the discharge. Ambipolar diffusion would apparently be important for low-energy particles.

Table 1 shows the ratios of the mean free paths of various charged particles and neutral molecules to the diameter of the discharge tube.

To evaluate the mean free paths with respect to ion–molecule collisions we use data on the drift velocity in strong electric fields.[11] The mean free path of nitrogen molecules is evaluated from viscosity measurements at 500°K (ref. 11).

For electron–molecule collisions at high energies we use the reduced mean free path found[11] for electrons from the absorption coefficient of electrons in the given gas.[12] The degree of ionization of the gas is assumed low.

Comparison of the data in this table with the experimental results in Figs. 2a and 2b reveals that the effective current reduction in a discharge limited by insulating surfaces is caused by the same factors which cause the increase in the mean free paths of the charged particles in comparison with the characteristic dimension of the discharge gap. There is a relative decrease in the current when the tube diameter or gas pressure is reduced or when the particle energy is increased.

The transverse loss due to charged-particle diffusion depletes primarily the peripheral regions of the discharge, leading to the formation of an active discharge zone at the tube axis, to a narrowing of the negative glow, and to a contraction of the cathode spot (see, e.g., Figs. 1c and 1d). The spot diameter can be determined for various voltage drops and working-chamber pressures from the erosion tracks on the cathode surface (Fig. 1c). Figure 2d shows the minimum spot diameter as a function of the maximum voltage drop for various pressures. A narrowing of the negative glow and a contraction of the cathode spot have been observed in hindered discharges at higher pressures and lower voltage drops previously,[9,10] but under those conditions the effects are not as pronounced. At low working-chamber pressures and at large voltage drops the spot can narrow to a diameter of 0.8 mm, and a further increase in the voltage drop (beyond a certain critical value) or a further pressure reduction cuts off the current (for a given tube diameter).

The concentration of the discharge in the axial region and the contraction of the cathode spot which occur when the voltage drop is increased or the pressure reduced are accompanied by an increase in the current density at the cathode spot (Fig. 2d); this increase causes a local heating of the cathode and intensifies the formation of a central discharge zone.

Since the trajectories of most of the electrons in the cathode fall are essentially linear and normal to the cathode surface, any cross-section of the electron beam not too far from the cathode is a projection of the cathode spot in a hindered discharge (Fig. 1d). Accordingly, the intensity of the collimated electron beam emerging from the anode aperture is governed by the current density at the cathode spot. We in fact observe an increase in the beam current (measured with a Faraday cup in the working chamber 120 mm from the exit limiter; Figs. 2d and 2e) when the current density increases.

The negative glow plays an important role in shaping and stabilizing an extended hindered discharge: It furnishes photons, ions, and (at large V_a) x rays which induce electron emission from the cathode. We therefore study how a constriction in the insulating surface near the negative glow affects the discharge characteristics. In these experiments we use a quartz insulator of simple shape (3 in Fig. 1b). The voltage–current characteristics of a discharge in a discharge tube with a constricted insulator lie considerably below those for a discharge in a cylindrical insulator at high pressures (Figs. 2c and 3). At low pressures, the characteristics rise in the region of large voltage drops because of the supply of insulator material directly in the discharge zone. For the same reason, the transition from a discharge with an ascending characteristic to one with a descending characteristic occurs at a lower voltage than in the case of a cylindrical insulator. A distinctive feature of discharges in a constricted tube is the earlier cutoff of the current at high voltages and low gas pressures. In the hatched region in Fig. 2c a steady-state glow discharge with an ascending characteristic cannot exist.

Timofeeva[13] and Granovskii[14] observed a current cutoff in a constricted low-pressure tube operating under conditions corresponding to high-current arc discharges; they have offered an interpretation for this effect and suggested several practical applications. However, this effect has apparently not been observed previously in extended, hindered glow discharges. In this latter case the nature of the cutoff is slightly different. The mean free paths of the charged particles are comparable to or much larger than the diameter of the constricted part of the tube (Table 1). The concentration of the discharge at the axis becomes even more pronounced, and the cathode spot is very small (~ 0.5 mm at 10 kV and p = 0.084 torr); with a further increase in V_a or decrease in p the charged-particle density in the active zone turns out to be insufficient for the maintenance of a stable discharge, so that the current is cutoff. At pressures below 0.080–0.09 torr an increase in V_a is not accompanied by an immediate current cutoff; instead there is initially an unstable pulsating discharge. With a further increase in V_a the pulsation frequency decreases, and finally, at some $V_{a\,cr}$, the current is cutoff.

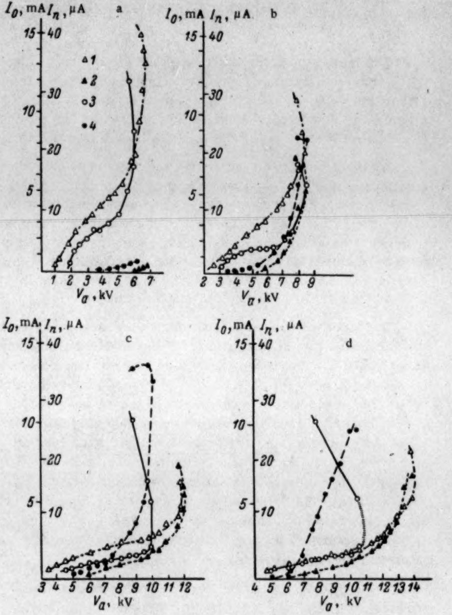

Fig. 3. Comparative characteristics of the discharges and electron-beam currents for discharges in cylindrical insulators and in constricted insulators, for various pressures in the working chamber. p, torr: a) 0.25; b) 0.15; c) 0.105; d) 0.084. 1, 3) Discharge current; 2, 4) beam current; 1, 2) cylindrical tube; 3, 4) constricted tube.

The apparent explanation is that at breakdown, which occurs at $V_{br} > V_{st}$ and at gas pressure and temperature p_{br} and T_{br}, some material is supplied from the cathode to the gap, the density increases, and V_a falls. As the evacuation continues, the pressure is reduced slightly, the density is also reduced, the gas temperature exceeds T_{br}, and V_a increases, approaching its steady-state value. In addition, the cathode spot expands, the transverse loss increases, and the current is cut off; then the process is repeated.

The increase in the discharge-current density caused by the tube constriction leads to an increase in the intensity of the collimated electron beam (Fig. 2e), to a level higher than that in a cylindrical tube; however, the electron beam fills a smaller volume and its energy is lower.

Figure 3 compares the characteristics of hindered discharges in cylindrical tubes with those in constricted tubes; shown here are the voltage–current characteristics of the discharges and the current of the collimated electron beam as a function of the voltage drop across the gap for various pressures in the working chamber. The beam current is measured with a Faraday cup while the beam is limited by a metal limiter 0.8 mm in diameter.

The electron emission increases with increasing voltage for both types of insulators. This result can be attributed to the concentration of the discharge at the axis as a result of diffusive loss and to the increased absorption and scattering of electrons in the gas because of their increased energy; e.g., at energies above 800 eV fewer than 1% of the electrons are scattered through angles larger than 1° (ref. 11). As the electrons increase in energy the scattering characteristic becomes even narrower.¹⁾ The combination of insulator, anode exit aperture, and limiter, with a small cathode spot and at high electron energies, acts as a natural filter for slower electrons, which are scattered through large angles.

We study the electron energy distribution over the working ranges of p and V_a by the retardation method. The apparatus for retarding the electrons is placed in the working chamber of the vacuum tube, where it is mounted on a three-coordinate manipulator. The error in the readings of two of the coordinates is on the order of 0.05 mm. The electrons enter this apparatus some 120-125 mm away from the point at which they leave the source. Replaceable limiters with apertures from 2 to 0.05 mm are used at the entrance to the retarding apparatus for studying the current distribution in the spot. The working cavity in this apparatus is evacuated to $2\text{-}5 \cdot 10^{-5}$ torr through flexible tubing. Figure 2f shows an illustrative energy distribution for a working-chamber pressure on the order of 0.15 torr and for various voltage drops. As the voltage drop across the gap is increased, the beam becomes more nearly monoenergetic. The averaging interval in the electron energy distribution is 0.25 keV. The electrons observed at relatively low energies results from the slowing of electrons in collisions with gas molecules between the electron source and the energy analyzer. In a hindered discharge the average electron energy is approximately equal to the voltage drop across the gap. Figure 2g shows the current distribution over the spot for the same working-chamber pressure. Under all conditions the beam divergence is less than 1°.

This description of the electron characteristics would be incomplete without mention of the difference between the characteristics corresponding to insulators of different shape at the transition from an ascending voltage–current characteristic to a descending one: While the electron-beam current continues to increase at the beginning of the descending branch when the cylindrical insulator is used, it falls off in the case of the constricted tube. This behavior can be attributed to marked heating of the constriction (to white heat), which is accompanied by the appearance of many thermal electrons and ions, which in turn disrupt the mechanism outlined above.

On the basis of these results regarding the cutoff of the hindered-discharge current at large ratios of the charged-particle mean free paths to the diameter of the quartz discharge tube and on the basis of studies[8,10] of the limitation of a discharge by insulating surfaces, we can recommend the use of a narrow insulating channel, along with systems of limiters and metal injection needles, for extracting the electron beam into the working chamber. In particular, a quartz capillary (1 in Fig. 1a) with an inside diameter of 1.2 mm led to a 40-50% increase in the breakdown voltage in the outer part of the working chamber under the specified experimental conditions. The source described here is used successfully to visualize tenuous gas flows.

RESULTS

1. Limiting the cathode region of a hindered glow discharge with insulating surfaces sharply reduces the current because of transverse diffusive loss, increases the discharge resistance, and requires an increase of 20-25 kV in the voltage supplied to the discharge gap, when the mean free paths for the charged particles are comparable to the characteristic dimensions of the insulating surfaces.

2. The current reduction due to transverse loss occurs primarily in the periphery of the discharge, causing the cathode spot to contract to a very small size (as small as 0.8 mm) at high voltage drops and at low pressures.

3. At low pressures and high voltages, effective limitation of the discharge, especially in the negative glow, leads to a cutoff of the current and ends the operation of the source.

4. When the discharge is significantly concentrated near the axis of the discharge tube, the current density at the cathode spot is high, the pressure is low, and the voltage drop is high, the apparatus described here is a source of high-energy collimated electrons with a narrow energy spread.

In conclusion the author thanks B. I. Zaslavskii for his continued interest.

---

1) Here and below we use the customary terminology in describing the characteristics, but the coordinate axes are interchanged for convenience in interpreting the current characteristics of the channeled-electron beam.

General

Nonradiative electron transitions and thermal effects in laser-irradiated transparent dielectrics

B. I. Makshantsev, A. A. Kovalev, R. K. Leonov, and P. A. Yampol'skii

(Submitted October 30, 1972; resubmitted June 29, 1973)
Zh. Tekh. Fiz., 44, 164-172 (January 1974)

We discuss the heating of a cluster of impurity centers in a transparent dielectric irradiated by a laser pulse, taking account of the temperature dependence of the nonradiative electron transitions in the centers. It is assumed that the centers absorb the laser light. It is shown that the temperature in such a cluster is a nontrivial function of the number of impurity particles and the intensity of the laser radiation. An explanation is offered for the experimental size of the photocurrent induced by laser radiation in crystalline quartz, and its dependence on the radiation intensity.

Among the mechanisms for the fracture of transparent solid dielectrics by giant laser pulses the one which has received the greatest recognition is electric breakdown in the field of the light wave.[1-3] It has been shown experimentally[3,4] that no electron avalanche is generated by ruby laser radiation with an intensity lower than threshold by more than an order of magnitude, but a substantial photocurrent is observed. At the present time the production of free electrons by laser radiation is explained by multiphoton ionization,[4,5] but estimates show that the number of electrons formed during the irradiation time $\tau \approx 4 \cdot 10^{-8}$ sec should be substantially smaller than the experimentally observed value.

The probability of multiphoton ionization per unit time, w, is given by[5]

$$w = \omega\left(\frac{\omega_0}{\omega}\right)^{3/2} \exp\left[2E\left(\frac{\omega_0}{\omega}+1\right)-\frac{\omega_0}{\omega}\right]\left(\frac{I}{I'}\right)^{E\left(\frac{\omega_0}{\omega}+1\right)}. \qquad (1)$$

Here ω is the frequency of the photon, $\hbar\omega_0$ is the ionization potential, the symbol E(. . .) denotes the integral part of a number, and $I' = 2mc_0\omega^2\hbar\omega_0/\pi e^2$, where m is the mass of an electron, c_0 is the velocity of light, and e is the electron charge. Using Eq. (1) for crystalline quartz,[4] where $\hbar\omega \approx 7$ eV, irradiated by light from a ruby laser with intensity $I = 2 \cdot 10^8$ W/cm² we find the number of free electrons $N_e = Nw\tau = 2 \cdot 10^7$ cm^{-3}, which is significantly smaller than the experimental value[4] $Ne \approx 10^{11}$ cm^{-3}. Here, $N \approx 5 \cdot 10^{22}$ cm^{-3} is the bound electron density under the assumption that oxygen atoms are ionized.[3]

Since experiment shows that the dependence of the photocurrent on intensity is strongly nonlinear, it is impossible to account for the photoconductivity by ionization of other traps. Estimates of the size of the photocurrent made by using the theory of multiphoton ionization for equidistant intermediate levels[4] are not satisfactory since these levels are not found experimentally.

Thus, in spite of the importance of the question of the size of the photocurrent which precedes optical fracture and apparently is closely related to it, existing theory does not give a satisfactory explanation of the size of the photocurrent produced in transparent dielectrics by laser radiation.

It is also necessary to take account of the fact that the experimentally observed threshold values[1-3] of the radiation intensity at which the fracture of transparent dielectrics begins are smaller than the theoretical values calculated by the theory of light breakdown by more than two orders of magnitude.[1,2] In addition, at least for a ruby laser, fracture by multiphoton ionization should be observed before the theoretical threshold for breakdown.

On the basis of the above considerations it is clear it is of great interest to consider another model of the interaction of laser radiation with transparent dielectrics.

In ref. 6 local heating of a dielectric is considered a consequence of nonradiative electron transitions in impurity centers absorbing laser radiation. It is known[7,8] that impurities tend to form clusters 100-1000 Å in diameter in semiconductors and dielectrics. Therefore it is of interest, from the point of view of the problem of optical fracture of transparent dielectrics, to investigate the heating of such a cluster in exposure to laser radiation, taking account of the temperature dependence of the probability of a nonradiative electron transition of impurity centers. By an impurity center we mean an impurity particle with its immediate surroundings.

DERIVATION OF THE FUNDAMENTAL EQUATION

We assume that the clusters are spherical. In addition we assume that the density of the clusters is so small that their interaction can be neglected. We consider a cluster of radius $R = n^{1/3}r_0$. Here, n is the number of centers in the cluster and $2r_0$ is the distance between neighboring centers. The number n is assumed to be such that $2RK_\omega \ll 1$, where $K_\omega = \sigma n/(4\pi R^3/3)$, and σ is the cross section for the absorption of laser radiation by a single center. For the two-level model of an absorbing center

$$\frac{dP}{dt} = -\left[\frac{2\sigma(T)I}{\varepsilon}+\nu(T)\right]P+\frac{\sigma(T)I}{\varepsilon}, \qquad (2)$$

where P is the probability of finding a center in the excited state, ε is the energy of a photon, and $\nu(T)$ is the probability of a nonradiative electron transition in a center, depending of the time t, and, generally, on the position of the center in the cluster. The quantity $\nu(T)$ is ordinarily given by an Arrhenius relation of the form $\nu(T) = A\exp[-W/k(T+T_0)]$, where we take the initial temperature T_0 as the zero temperature reading, and A and W are constants. In Eq. (2) the intensity of the laser radiation is assumed to be so large that spontaneous radiative transitions can be neglected. By assuming the mean free path of a phonon to be appreciably smaller than the size of a cluster we can write the heat-conduction equation for the temperature T as

$$\frac{\partial T}{\partial t}=\operatorname{div}\,[\varkappa f(r)+\varkappa'(1-f(r))]\operatorname{grad}T+F(t,\ T)f(r). \tag{3}$$

In Eq. (3) $\varkappa = \lambda(T)/c\rho$ is the diffusivity, where $\lambda(T)$, c, and ρ are respectively the thermal conductivity, the specific heat, and the density of the material in the cluster, and $\varkappa'$ is the diffusivity of the material outside the cluster. We assume that c, ρ and c', ρ' are independent of temperature. The function $f(r) = 1$ if $|\mathbf{r}| = r \leq R$, and $f(r) = 0$ if $r > R$. The function $F(t, T) = \varepsilon\nu(T)P(t, T)/(4\pi r_0^3 c\rho/3)$. We note that the time τ the laser radiation acts on the material is omitted in Eqs. (2) and (3). This can be done since we are interested in the temperature inside a cluster, and this temperature is established in a time much shorter than τ.

To investigate the characteristics of Eqs. (2) and (3) it is necessary[9] to investigate the solution of these equations as a function of the parameters entering them under stationary conditions. We find the equation for the temperature $\bar{T}$ at the center of a cluster. Taking account of the boundary conditions, from Eq. (3) for the steady-state case we have

$$\left.\begin{aligned}\int\limits_0^{T(r)}\varkappa\,dT&=\chi(r),\\ \int\limits_0^{T(r=R)}\varkappa'\,dT&=\frac{1}{R}\int\limits_0^R Fr'^2\,dr',\end{aligned}\right\} \tag{4}$$

where $\chi(r) = -\int\limits_0^r Fr'(1 - r'/r)dr' + \int\limits_0^R Fr'(1 - r'/r)\,dr' + \int\limits_0^{T(r=R)} \varkappa dT$. The first equation in (4) gives $R(r) = \varphi(\chi(r))$, and the second gives $T(r = R)$. We consider the case in which $F(T(r))$ is a slowly varying function up to a value of r close to R. Then, writing F(T) in the form $F(\bar{T}) + F[T(r)] - F(\bar{T})$, where $F[T(r)] - F(\bar{T})$ is a small correction, the expression for $\chi(r)$ can also be written as a main term plus a small correction $\chi = \chi_0(r) + \chi_1(r)$. Then,

$$\chi_0=\frac{F(\bar{T})}{6}(R^2-r^2)+\int\limits_0^{T(r=R)}\varkappa\,dT$$

and

$$\chi_1=-\int\limits_0^r[F(T(r'))-F(\bar{T})]\left(1-\frac{r}{r'}\right)r'dr'$$

$$+\int\limits_0^R[F(T(r'))-F(\bar{T})]\left[1-\frac{r'}{R}+\frac{\varkappa(r=R)}{\varkappa'(r=R)}\frac{r'}{R}\right]r'dr'.$$

If

$$\langle\chi_0\rangle\gg\langle|\chi_1|\rangle\ \text{and}\ \langle\varphi(\chi_0)\rangle\gg\left\langle\left|\frac{\partial\varphi}{\partial\chi_0}\chi_1\right|\right\rangle, \tag{5}$$

where the symbol $\langle\ldots\rangle$ denotes averaging over the volume of a cluster, $T(r) = \varphi[\chi_0(r)]$, and Eqs. (4) for determining the temperature take the form

$$\left.\begin{aligned}\int\limits_0^{T(r)}\varkappa\,dT&=\chi_0(\bar{T},\ r)&&(r\leqslant R),\\ \int\limits_0^{T(r=R)}\varkappa'\,dT&=\frac{1}{3}F(\bar{T})R^2&&(r>R).\end{aligned}\right\} \tag{6}$$

Determining $T(r) = \varphi(r, \bar{T})$ from (6) and setting $r = 0$ we obtain the equation for $\bar{T}$

$$\bar{T}=\varphi(r=0,\ \bar{T}). \tag{7}$$

We note that Eq. (7) is valid only when (5) is satisfied.

In our work we consider crystals in which, according to theory, the diffusivity is inversely proportional to $T_0 + T$ for sufficiently high temperature,[7] i.e.,

$$\varkappa(T)=\frac{\varkappa_0}{1+\frac{T}{T_0}}\ \text{and}\ \varkappa'=\frac{\varkappa_0'}{1+\frac{T}{T_0}}.$$

However, this relation is valid only up to the temperature at which the portion of the crystal under consideration melts. This temperature can be estimated in the following way. The order of magnitude of the characteristic time of a phase transition can be found from

$$\tau_m\simeq\tau_0\exp\left[\frac{U}{k(T+T_0)}\right],$$

where $1/\tau_0$ is the frequency of the atomic vibrations controlled by the bond which is broken as a result of the melting of the material,[10] $U = 0.5 + 0.7$ D, and D is the binding energy of the atoms involved. If τ is the time the laser radiation acts on the material, the maximum temperature of the crystal before it melts is estimated from the condition $\tau \sim \tau_m$. Hence

$$T\simeq\frac{\frac{U}{k}}{\ln\frac{\tau}{\tau_0}}-T_0\simeq\frac{\frac{U}{k}}{\ln\frac{\tau}{\tau_0}}\,\frac{\frac{U}{k}}{\ln\frac{\tau}{\tau_0}}\gg T_0.$$

Thus the relation $\varkappa = \varkappa_0/(1 + T/T_0)$ and $\varkappa' = \varkappa_0'/(1 + T/T_0)$ will hold only for $T \nless (U/k)/\ln(\tau/\tau_0)$. For example, for crystalline quartz in which the Si–O bond is broken, with $\tau_0 \approx 10^{-4}$ sec and $U \approx 3$ eV, we obtain $T \nless 2500°$ for $\tau = 4 \cdot 10^{-8}$ sec.

When the temperature established in the cluster is so high that $\langle T\rangle \gg (U/k)/\ln(\tau/\tau_0)$, the whole cluster and an appreciable region around it will be in the molten state. In the molten material the diffusivity is assumed to be independent of temperature and equal to $\varkappa_m$ inside the cluster and $\varkappa_m'$ outside it. Then, since $\langle T\rangle \gg (U/k)/\ln(\tau/\tau_0)$ Eqs. (6) and (7) are used, as before, to find the temperature inside the cluster, but we must set $\varkappa = \varkappa_m$ inside the cluster and $\varkappa = \varkappa_m'$ outside it. At fusion all the parameters appearing in F(T) are assumed constant. In particular, the distance between centers $2r_0$ can be considered constant since the viscosity of the liquid is high at the temperatures of interest.

Taking account of the above, from Eqs. (6) we have

$$T(r)=T_0\left\{\exp\left[\psi(\bar{T})\left(1-\frac{\frac{r^2}{R^2}}{\frac{2\varkappa_0}{\varkappa_0'+1}}\right)\right]-1\right\}\ \text{for}\ T\ll\frac{\frac{U}{k}}{\ln\frac{\tau}{\tau_0}} \tag{8}$$

and

$$T(r) = T_0 \frac{\varkappa_0}{\varkappa_m} \frac{\frac{2\varkappa_m}{\varkappa'_m + 1}}{\frac{2\varkappa_0}{\varkappa'_0 + 1}} \psi(\bar{T}) \left(1 - \frac{\frac{r^2}{R^2}}{\frac{2\varkappa_m}{\varkappa'_m + 1}}\right) \text{ for } T \gg \frac{\frac{U}{k}}{\ln \frac{\tau}{\tau_0}},$$

where $\Psi(\bar{\bar{T}}) = F(\bar{\bar{T}}) R^2 (2\varkappa_0/\varkappa'_0 + 1)/6\varkappa_0 T_0$.

Introducing the dimensionless temperature $\Theta = \alpha \bar{\bar{T}}$, where $\alpha = W\ kT_0^2$, taking account of the fact that $R = n^{1/3} r_0$, and using Eqs. (2) and (8), we transform Eq. (7) to the form

$$\Theta = \Phi(\Theta), \tag{9}$$

where

$$\Phi(\Theta) = \Theta_0 [\exp \psi(\Theta) - 1] \text{ for } \Theta \leqslant \frac{\frac{\alpha U}{k}}{\ln \frac{\tau}{\tau_0}}$$

and

$$\Phi(\Theta) = \Theta_0 \frac{\varkappa_0}{\varkappa_m} \frac{\frac{2\varkappa_m}{\varkappa'_m + 1}}{\frac{2\varkappa_0}{\varkappa'_0 + 1}} \psi(\Theta) \text{ for } \Theta \gg \frac{\frac{\alpha U}{k}}{\ln \frac{\tau}{\tau_0}}.$$

Here

$$\psi(\Theta) = \frac{1}{e\Theta_0} \left(\frac{n}{n_0}\right)^{2/3} \frac{I}{I'} \frac{\exp\left[\frac{\Theta\Theta_0}{(\Theta + \Theta_0)}\right]}{\frac{I}{I'} + \exp\left[\frac{\Theta\Theta_0}{(\Theta + \Theta_0)}\right]},$$

$\Theta_0 = \alpha T_0$, $e = 2.718\ldots$, $I' = I_0 \sigma(\Theta)/\sigma_0$, $I_0 = \varepsilon \nu_0 / 2\sigma_0$ and $\sigma_0 = \sigma(T + T_0 = 0°K)$, where $\nu_0 = A \exp(-W/kT_0)$, and

$$n_0 = \left[\frac{16\pi c p \varkappa_0 r_0}{e \varepsilon \alpha \nu_0 (1 + 2\varkappa_0/\varkappa'_0)}\right]^{3/2}.$$

INVESTIGATION OF THE FUNDAMENTAL EQUATION

We investigate the characteristics of the solution of Eq. (9) as a function of the parameters. For given transparent dielectrics and impurity centers the only variable parameter in Eq. (9) is n, the number of centers in a cluster. For certain values of n the temperature Θ as a function of intensity can experience a jump at $I = I_{cr}(n)$. This is shown in Fig. 1 where the solution of Eq. (9) is plotted for three values of the intensity $I_1 < I_2 = I_{cr} < I_3$ for n close to $n_0 (n > n_0)$. If I approaches $I_{cr} (I < I_{cr})$, i.e., if curve 1 approaches curve 2, the solution Θ_1 approaches1) the solution $\Theta_2 = \Theta_{cr}$. If $I > I_{cr}$ and $I \to I_{cr}$, no matter how close curves 2 and 3 are to each other, the solution Θ_3 does not approach Θ_{cr}. To find I_{cr} as a function of n and the other parameters it is necessary, as is clear from Fig. 1, to find Θ_{cr} and I_{cr} from the equations

$$\Theta_{cr} = \Phi(\Theta_{cr}, I_{cr}),$$

$$1 = \frac{\partial}{\partial \Theta_{cr}} \Phi(\Theta_{cr}, I_{cr}).$$

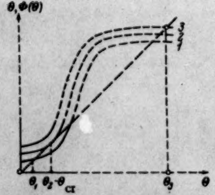

Fig. 1. Solution of Eq. (9) for three values of the intensity $I_1 < I_2 = I_{cr} < I_3$ for $n \approx n_0 (n > n_0)$. The open curves are plotted on an arbitrary scale.

We consider the usual situation $\Psi(\Theta_{cr}, T_{cr}) \ll 1$, $\Theta_{cr} \ll \Theta_0$, and $\sigma(\Theta) \approx \sigma_0$ for $\Theta \nless \Theta_{cr}$. Taking account of the form of the function $\Phi(\Theta)$ for small values of Θ for the above set of equations we have

$$\left.\begin{aligned} \Theta_{cr} &= \frac{I_{cr}}{eI_0} \left(\frac{n}{n_0}\right)^{2/3} \frac{\exp \Theta_{cr}}{\frac{I_{cr}}{I_0} + \exp \Theta_{cr}}, \\ 1 &= \frac{1}{e} \left(\frac{I_{cr}}{I_0}\right)^2 \left(\frac{n}{n_0}\right)^{2/3} \frac{\exp \Theta_{cr}}{\left[\frac{I_{cr}}{I_0} + \exp \Theta_{cr}\right]^2}. \end{aligned}\right\} \tag{10}$$

We note that (5) is satisfied at $\Theta = \Theta_{cr}$. This follows the first equation in (8) and the relations $\Psi(\Theta)_{cr}, I_{cr}) \ll 1$, and $\sigma(\Theta) = \text{const}$. Analysis of Eq. (10) shows that when the conditions mentioned above are satisfied $\Theta = \Theta(I)$ determined from Eq. (9) behaves as follows:

If $n < n_0$, $\Theta = \Theta(I)$ increases continuously with increasing intensity and approaches a limiting value smaller than unity. Thus, clusters containing a number of particles $n < n_0$ are not of interest since such clusters will always exhibit a low temperature.

If $n_0 \leq n < n'_0$, where $n'_0 = n_0 (4/e)^{3/2}$, $\Theta = \Theta(I)$ is an increasing function having a jump at $I = I_{cr}(n)$ and approaching a limiting value as $I \to \infty$.

For $n - n_0 \ll n_0$ $I_{cr}(n) \approx (3eI_0/2)/\ln(n/n_0)$, and

$$\Theta_{cr}(n) \simeq 1 - \frac{2}{3} \ln \frac{n}{n_0}. \tag{11}$$

$$\text{for } \sqrt{1 - n/n'_0} \ll 1 \quad I_{cr}(n) \simeq e^2 I_0 \left(1 + \frac{4}{3} \frac{(n'_0 - n)}{n'_0}\right) \text{ and}$$

$$\Theta_{cr}(n) \simeq 2\left(1 - \sqrt{\frac{2}{3} \frac{n'_0 - n}{n'_0}}\right). \tag{12}$$

Since it follows from (11) and (12) that $I \leq \Theta_{cr} \leq 2$, the inequality $\Psi(\Theta_{cr}, I_{cr}) = \Theta_{cr}/\Theta_0 \ll 1$ assumed above is satisfied. Ordinarily $T \approx 300°K$ and $W \sim 1000\ \text{cm}^{-1}$, and therefore $\Theta_0 = W/kT_0 \sim 4$. The assumption that the cross section for the absorption of monochromatic light $\sigma(\Theta)$ is constant for $\Theta \sim \Theta_{cr}$ is also well substantiated. For example in the harmonic approximation[11]

$$\sigma(\Theta) = \frac{\sigma_0}{1 - \xi} \exp\left(-\frac{2\xi y^2}{1 - \xi}\right) I_{l-0}\left(\frac{2y^2}{1 - \xi}\right). \tag{13}$$

Here, σ_0 is the cross section for the absorption of a photon at absolute zero,

$$\xi = \exp\left(-\frac{\hbar\omega_{vib}}{W} \frac{\Theta_0^2}{\Theta + \Theta_0}\right),$$

where $\omega_{vib} \sim 500\text{-}1000\ \text{cm}^{-1}$ is the frequency of vibrational motion inside an impurity center, $y \leq 1$, and $I_{l=0}[2y^2/(1-\xi)]$ is the zero-order Bessel function of imaginary argument. Since $\hbar\omega_{vib} \sim W$, for $\Theta \sim \Theta_{cr} \ll \Theta_0$, $\xi \ll 1$, and $\sigma(\Theta) \approx \sigma_0$.

The jump in the temperature Θ is a maximum when $n = n_0(I_{cr} = \infty)$ and is equal to

$$\Theta - \Theta_{cr} \simeq \Theta \simeq \frac{\varkappa_0}{\varkappa_m} \frac{\frac{2\varkappa_m}{\varkappa'_m + 1}}{\frac{2\varkappa_0}{\varkappa'_0 + 1}} e^{\Theta_0 - 1}.$$

An n increases the temperature jump decreases and vanishes at $n = n'$. Finally for $n \geq n'_0$ $\Theta = \Theta(I)$ is a continuously increasing function of the intensity, approaching a maximum. The inequality (5) is satisfied also at high temperatures ($\Theta_0 \nless \Theta$).

Thus it is clear that for a sufficiently high radiation intensity a high temperature is reached only in cluster with $n > n_0$. We estimate the temperature $\overline{T} = \Theta/\alpha$ for crystalline quartz when n the number of particles in a cluster is close to n_0 and the intensity $I = I_{cr}(n) + 0$. It will be seen that $\overline{T} \gg (U/k)/\ln(\tau/\tau_0)$. Therefore, using Eq. (9) for this case and setting $\varkappa_0 = \varkappa'_0$, $\varkappa_m = \varkappa'_m$, $\Theta_0 = 3.8$, $e^{\Theta_0}\Gamma/I \approx (2/3)e^{\Theta_0 - 1}[\sigma_0/\sigma(\Theta)]\ln(n/n_0) = 0.75$, and $T_0 = 300$°K and using the fact that $\varkappa_0/\varkappa_m = 6.7$ and $\Theta \gg \Theta_0$ for quartz we obtain[2)] $T = T_0(\varkappa_0/\varkappa_m)\Psi(\varkappa_0) \approx 6 \cdot 10^3$°K.

We determine the values of I, I_0, Γ, and n corresponding to this temperature. For $\nu_0 = 10^9$ sec^{-1}, $\varepsilon = 1.78$ eV, $\sigma_0 = 10^{-17}$ cm^2, and $\sigma(T = 6 \cdot 10^3$°K$) = 4.3 \cdot 10^{-17}$ cm^2 (since at high temperatures according to Eq. (13) $\sigma(\Theta) = \sigma_0 e^{2y^2} \cdot (4\pi y^2 \alpha \hbar\omega_{vib}/k\Theta)^{-1/2}$ we have $I_0 = 1.4 \cdot 10^7$ W/cm^2, $\Gamma = 3.3 \cdot 10^6$ W/cm^2, and $I = e^{\Theta_0}\Gamma/0.75 = 2 \cdot 10^8$ W/cm^2. By setting $c\rho\varkappa_0 \approx 2 \cdot 10^{-2}$ cal/cm sec deg and $r_0 = 10^7$ cm we obtain $n \sim n_0 = 1.7 \cdot 10^6$. For the parameters chosen all the conditions assumed above are satisfied. In particular for the time to establish a steady-state temperature in a cluster we have the inequality

$$\frac{R^2}{4\varkappa_0} = \frac{n^{2/3} r_0^2}{4\varkappa_0} < \tau_{st} < \frac{R^2}{4\varkappa_m}.$$

Consequently $\tau_{st} \ll \tau$, since $10^{-9} < \tau_{st} < 6 \cdot 10^{-9}$ sec, and $\tau = 4 \cdot 10^{-8}$ sec.

PHOTOCONDUCTIVITY

Free electrons appear in clusters at high temperatures as a result of thermal ionization. The electron density $n_e(r)$ can be estimated by the Saha equation

$$\frac{n_e^2}{N} = 6 \cdot 10^{21} T_{eV}^{3/2} \exp\left(-\frac{J}{kT(r)}\right), \tag{14}$$

which holds qualitatively in the case under consideration. In Eq. (14) N is the particle density of the host material, and $J = \hbar\omega$ is its ionization potential, which is assumed not to decrease. T_{eV} is the temperature in electron volts. Equation (14) assumes the equality of the statistical weights of an ion and a neutral particle. Using (14) and (9) and the fact that

$$\frac{\frac{r^2}{R^2}}{\frac{2\varkappa_m}{\varkappa'_m + 1}} \ll 1 \text{ and } \frac{J}{2\left(\frac{2\varkappa_m}{\varkappa'_m + 1}\right)kT} \geqslant 1,$$

we have for the electron density averaged over the volume of a cluster

$$\langle n_e \rangle = \frac{3\pi}{2}\sqrt{15N} \cdot 10^{10} T_{eV}^{3/4}\left(2\frac{\varkappa_m}{\varkappa'_m} + 1\right)\frac{\exp\left(-\frac{J}{2kT}\right)}{\left(\frac{J}{2kT} + \frac{3}{4}\right)^{3/2}}.$$

Substituting into this expression the values of I, ν_0, σ_0, n_0, etc. chosen above, we obtain $\langle n_e \rangle \approx 10^{19}$ cm^{-3}. Thus heating produces an appreciable local density of free electrons in a cluster. If among the impurity clusters with $n > n_0$ there are mainly clusters with $n \approx n_0$, it follows from the above that the appearance of free electrons in clusters as a result of laser radiation will have a threshold. As will be seen later, it follows from this that the appearance of photoconductivity also has a threshold.

It is interesting to note that such clusters are favorable for the beginning of the development of an electron avalanche in the focal volume.

It appears that this is a possible explanation of the previously noted divergence of the experimental and theoretical values of the intensity of laser radiation at which breakdown occurs.

We note that in Eqs. (3) and (4) the heating of the material as a result of the interaction with the lattice of free electrons accelerated in the field of a light wave should have been taken into account. For intensities $I = 2\text{-}5 \cdot 10^8$ W/cm^2 which interest us, the field of the laser radiation still does not lead to the development of an electron avalanche.[3]

We now consider the question of the size of the photocurrent produced by laser radiation in a transparent dielectric placed in a static electric field. Simple estimates show that the number of electrons leaving a heated clusters of impurity centers during the time of irradiation and taking part in photoconductivity is negligible small. However, because of the high electron density in a cluster an appreciable number of radiative recombinations occur, and this leads to the production of ultraviolet photons with energies higher than the ionization potential of the dielectric. These photons will produce ionization more or less uniformly over the focal volume and create free charge carriers. The density of ultraviolet photons produced per unit time can be estimated from the expression[10] $z = 4 \cdot 10^{23} N\sigma^0_{\omega_0} J^2_{eV} T_{eV}(r) \exp[-J/kT(r)]$ sec^{-1} cm^{-3}, where $\sigma^0_{\omega_0}$ is the cross section for the absorption of a photon of energy equal to the ionization potential in the ground state. Consequently the density of electrons taking part in photoconductivity is $N_e = N_c \langle z \rangle 4\pi r_0^3 \tau/3$, where N is the average density of the impurity centers. Using the second equation in (8) we have

$$N_e = 4 \cdot 10^{24} N N_c r_0^3 \left(\frac{\frac{2\varkappa_m}{\varkappa'_m + 1}}{\frac{J}{kT} + 1}\right)^{3/2} \sigma^0_{\omega_0} J^2_{eV} T_{eV} \tau \exp\left(-\frac{J}{kT}\right). \tag{15}$$

Here, the dependence of N_e on the intensity is given in

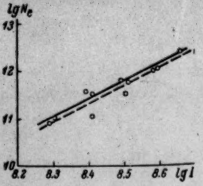

Fig. 2. Density of photoelectrons as a function of the intensity of laser radiation for crystalline quartz. Solid curve is experimental;[4] open curve is theoretical, obtained from Eq. (15).

terms of the temperature $\overline{T}$ by Eq. (9). In particular for crystalline quartz for an intensity $I = 2 \cdot 10^8$ W/cm^2 and values of the parameters chosen earlier, and assuming a density $N_c \sim 10^{14}$ cm^{-3} we obtain $N_e \approx 10^{11}$ cm^{-3}, which agrees with experiment.[4] Thus with the proposed model the theory offers an order of magnitude explanation of the experimental values of N_e for sufficiently low values of the intensity I. Moreover N_e as a function of I found from Eq. (15) by using the same values of the parameters for crystalline quartz is not in bad agreement with the experimental curve (Fig. 2).

CONCLUSION

We have considered a model of the interaction of laser radiation with transparent crystalline dielectrics based on the assumption that a small fraction of the impurity centers, which are good absorbers of laser radiation, are located in clusters. Under the action of radiation the clusters are heated as a result of nonradiative electron transitions in the impurity centers; the probability of the transformation of adsorbed energy into heat is assumed to depend exponentially on the temperature.

It is shown that if n, the number of the impurity centers in a cluster, is less than a certain value n_0 the temperature in the cluster is low (< 400°K) for any intensity of the incident radiation. If $n > n_0$ the cluster temperature $T \sim 10^4$°K for a certain intensity of the laser radiation. For clusters satisfying the condition $n_0 < n < (4/e)^{3/2} n_0$ the steady-state temperature $\overline{T}$ as a function of the intensity experiences a jump at $I = I_{cr}$. An expression has been obtained for the number of conduction electrons produced by a laser pulse in a transparent dielectric. This relation yields an explanation of the experimental size of the photocurrent and its dependence on the intensity of the laser radiation in crystalline quartz. The proposed model is based on the mechanism of the generation of free electrons by ultraviolet photons produced by radiative recombination in strongly heated clusters.

If most of the clusters in the dielectric contain a number of centers close enough to n_0, the dependence of the photopeak on intensity will experience a jump at $I = I_{cr}$ just as the temperature does.

For a sufficiently high intensity of the incident radiation strongly heated clusters can serve as centers from which an electron avalanche will propagate over the whole focal volume.

The discussion presented for transparent crystals can be applied to noncrystalline transparent dielectrics without any fundamental changes by assuming that the latter contain sufficiently large regions of crystallization containing the impurity centers we have considered. A similar assumption enables us to understand why the experimentally determined thresholds for the fracture of crystalline quartz and glass are nearly the same in spite of the great difference in their strength characteristics.

---

1) For the intensity I_1 shown in Fig. 1 Eq. (9) has three roots. The physical situation is described by the smallest root.

2) We choose the parameters such that later we can explain the experimental data on photoconductivity induced in crystalline quartz by laser radiation.

A study is made of the dielectric properties of porous ceramic materials at millimeter wavelengths. The transmission is found to drop sharply at certain frequencies (when the wavelength is about twice the mean diameter of the pores in the material). The more uniform the porosity of the material, the steeper the slope of the transmission curve. At large wavelengths the investigated materials are transparent and do not change their refractive properties. Porous ceramic materials show promise as filters for electromagnetic radiation.

Foamed ceramics are transparent at microwave frequencies and have a low value of dielectric constant. These new porous ceramic materials have already found successful application in a number of decimeter and centimeter devices, e.g., as fillers for loaded resonators and measuring lines operating under high-temperature conditions.

A study of the properties of foamed ceramics in the millimeter range is necessary in order to assess their possibilities at shorter wavelengths.

We have measured the refractive index and absorption in the millimeter range of a number of porous glazed ceramics with different chemical compositions, specific gravities, and characteristic pore diameter. The results are compared with data at 3 cm (see ref. 1).

The refractive index in the millimeter range is measured on a quasioptical setup (Rozhdestvenskii interferometer scheme).[2] One-dimensional ruled elements with a period much less than the radiation wavelength[3] serve as power dividers and polarizers in the interferometer. The coefficient of absorption is measured with an apparatus similar to that described in ref. 4. The measured variation of the transmission with wavelength for four samples is shown in Fig. 1. It can be seen that at λ = 3 mm the transmittance of all samples is greater than 80%, although for samples 3 and 4 it falls to 0.1% when the wavelength decreases to 1.5 mm. The transmission of samples 1 and 2 also falls off sharply but at shorter wavelengths. We cite in Table 1 the measured values of the refractive index n and the loss tangent tan δ of the investigated materials for λ = 3 cm and λ = 3 mm. It can be seen from these figures that the refractive index has no dispersion in the wavelength range from 3 cm to 3 mm. The increase in tan δ is probably due to the long-wave "tails" of the lattice absorption lines. The sharp drop in the transmission of the samples in the region 2.5–1 mm cannot be accounted for in this manner, however, since the measured transmission curves of solid samples having the same chemical composition as the investigated foamed samples have no sharp changes in this region.

TABLE 1

Sample No.	λ = 3 mm			λ = 3 cm	
	n	n^2	tg δ · 10^4	ε	tg δ · 10^4
1	1.30	1.69	20	1.70	3.0
2	1.16	1.35	30	1.36	10.0
3	1.20	1.44	25	1.44	2.0
4	1.26	1.59	27	1.60	2.8

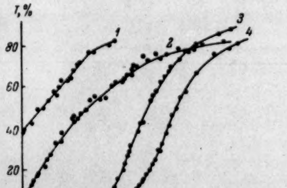

Fig. 1. Plots of transmission T versus wavelength λ for various porous samples.

The sharp change in the transmission of the foamed samples may be due to scattering of the incident radiation by the pores within the samples. To check this possibility an experiment has been set up to detect the scattered radiation. The experimental arrangement is shown schematically in Fig. 2. The radiation[5] from a monochromatic BWO is converted, with the aid of a horn-lens antenna and a ruled element,[3] into a plane linearly polarized wave which falls upon the sample (the latter is located behind the aperture of a diaphgram). The radiation receiver (an OAP-4) is mounted on a rotatable rod whose axis of rotation passes through the investigated sample. By scannning the receiver in angle it is possible to measure the radiation power transmitted through the sample along the optical axis of the system and also the power scattered at various angles. In these experiments the receiver is used without the lens. Its receiving area is 6 mm in diameter. The rotatable rod is 300 mm long and the resulting angular resolution is 1°. The results of the measurements are recorded on a two-coordinate pen recorder. The angle of rotation of the rod φ is recorded along the X axis of the recorder and the signal from the receiver along the Y axis. Traces obtained at λ = 3.1 and 2.0 mm are shown

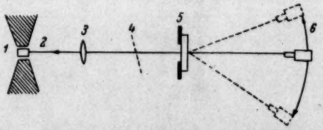

Fig. 2. Schematic diagram of apparatus for detecting scattering of millimeter radiation by sample. 1) Generator (backward wave tube); 2) horn; 3) lens; 4) polarizer; 5) diaphgram with investigated sample; 6) receiver.

in Fig. 3. It can be seen that radiation at $\lambda = 3.1$ mm drops about 20% from the initial intensity when it passes through the sample and that it retains its narrow-beam character. At $\lambda = 2.0$ mm the radiation intensity recorded by the receiver at $\varphi = 0$ is only 3.5% of its initial intensity. A randomly serrated scattering curve is observed, however, at angles of observation different from zero. As the investigated materials consist of a ceramic matrix within which spheroidal bubbles of air randomly distributed, it is clear that the porous structure of the material is responsible for the scattering of the electromagnetic radiation.

With a view to relating the wavelength of the scattered radiation to the characteristic parameters of the porous materials, the diameters of the pores are measured under the microscope and histograms plotted of pore density versus pore diameter. The resulting smoothed out distributions are shown in Fig. 4. A comparison of Figs. 4 and 1 yield the relationship between the shape of the pore size distribution curves and the frequency variation of the transmission of the corresponding samples, namely, the transmission curve is the less steep the larger the spread in the pore distribution. The scattering is almost complete when the wavelength is about twice the pore diameter. This situation is illustrated in Fig. 5.

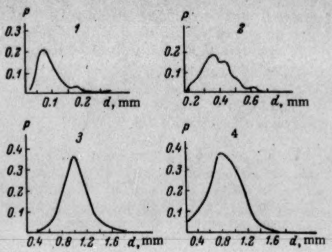

Fig. 4. Distribution of pores with respect to size for four samples 1-4.

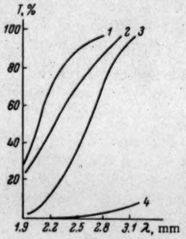

Fig. 5. Transmission curves for porous samples of same composition and thickness for different values of mean pore diameter 1) 0.64; 2) 0.8; 3) 1.07; 4) 1.43 mm.

CONCLUSIONS

Our millimeter wavelength investigation of porous ceramic materials has shown that at certain frequencies (radiation wavelength about twice the mean pore diameter) the transmission of the material drops sharply. The more uniform the porosity, the steeper the slope of the transmission curve. At long wavelengths foamed ceramics are transparent and do not change their refractive properties.

It appears that porous ceramic materials have potential use as cut-off filters for electromagnetic radiation.

Two-spin oscillator with optical orientation of electrons and nuclei

R. A. Zhitnikov and V. V. Semenov
M. I. Kalinin Polytechnic Institute, Leningrad
(Submitted June 7, 1973)
Zh. Tekh. Fiz., 44, 177-184 (January 1974)

A system of two spin oscillators with optical pumping of Cs^{133} and He^3 atoms located in a single absorption cell is described. The Cs^{133} spin oscillator is used to automatically stabilize a magnetic field. The application of the system of two spin oscillators in magnetometry and inertial sensing is studied experimentally and theoretically.

INTRODUCTION

Optically pumped spin oscillators have found wide application in quantum magnetometry;[1-4] quantum gyroscopes[5] based on this principle are also being studied. In these applications the optically pumped spin oscillator has many important advantages: signal-to-noise ratio independent of the field, continuous operation, high accuracy and stability, absence of a null shift, etc. However, the spin oscillators presently used in magnetometry operate on only one isotope and at a single frequency. Quantum gyroscopes use systems of two spin oscillators operating simultaneously on two isotopes of mercury: Hg^{199} and Hg^{201}. The frequencies of these two oscillators differ approximately by a factor of 3, which makes it possible, to a large extent, to take account of the magnetic field variations that give spurious deviations in the gyroscope readout.

It is of considerable interest to develop a system of two spin oscillators with optical pumping of two different elements in a single cell; one a nuclear paramagnetic material and the other an electronic paramagnetic material. This would make it possible to obtain two different (by two or three orders of magnitude) resonant frequencies in a strictly identical magnetic field, and to eliminate the effect of field gradients. In quantum magnetometry this would eliminate several errors due to frequency shifts which exist in contemporary quantum magnetometers. In quantum gyroscopes the use of electron paramagnetic resonance makes it possible to develop a system to effectively stabilize a magnetic field, as opposed to merely indicating its variation as is now the case.[6] Then the nuclear spin oscillator signal in a stabilized magnetic field contains the gyroscopic information about the angle and angular rate.

The present paper describes the design and investigation of a system of two spin oscillators with optical pumping, one of which operates at the magnetic resonance frequency of Cs^{133} [ν (Hz) = 3.5 · 10^5 H (Oe)], and the other at the NMR frequency of He^3 [ν(Hz) = 3.2 · 10^3 H (Oe)]. The signal from the Cs^{133} spin oscillator is used to stabilize the magnetic field, and the He^3 spin oscillator allows one to determine the field stability. This system encounters certain difficulties, since it is necessary to ensure a high degree of optical orientation of the Cs^{133} atoms in the presence of a gas discharge in the He^3 buffer gas, and nuclear orientation of the He^3 nuclei in the presence of a paramagnetic impurity in the form of atomic cesium. On the basis of this investigation we can evaluate experimentally and theoretically the feasibility of using the two-spin oscillator system in magnetometry and inertial sensing.

BASIC PROPERTIES OF SPIN OSCILLATORS WITH OPTICAL PUMPING OF Cs^{133} AND He^3 ATOMS

A block diagram of the optically pumped spin oscillator is shown in Fig. 1. Optical orientation of atoms of the working material is accomplished by circularly polarized radiation supplied by a spectral pumping lamp and a circular polarizer. At resonance the light to the photodetector is modulated at the Larmor frequency ω_0 (ref. 7). The ac voltage from the photodetector output is amplified, passed through a phase shifter, and applied to the radiofrequency coil. The system oscillates at the frequency ω_0 if the gain of the feedback loop is unity, and the total phase shift in the closed loop is zero. Both the Cs^{133} and He^3 spin oscillators operate in this manner. However, each of these oscillator systems has its own inherent characteristics related to the optical pumping process.

In the Cs^{133} spin oscillator the magnetic resonance line of the optically oriented atoms is an envelope of a set of Zeeman components, usually unresolved under the experimental conditions. With a change of the light intensity, cell temperature, and orientation of the optical system relative to the magnetic field the relative intensities of these components change, which causes a shift of the resonance line center and of the oscillation frequency.[8] In low magnetic fields additional frequency shifts occur due to higher harmonics of the transverse component of the magnetization vector. This is discussed in ref. 1, where the following expression is given for the frequency of a spin oscillator with zero phase shift in the feedback loop:

$$\omega = \omega_0\left(1 + \frac{1}{\omega_0^2\tau_2^2}\right)^{1/2}, \tag{1}$$

where τ_2 is the transverse relaxation time, which takes account of the effect of the pumping light. Then the maximum amplitude of the optical pumping signal S_x obtains at the frequency

$$\omega=\omega_0\left(1-\frac{1}{\omega_0^2\tau_2^2}\right)^{1/2}. \tag{2}$$

These frequency shifts severely limit the accuracy of magnetometers based on the Cs^{133} spin oscillator, particularly in measurements of weak magnetic fields where the Q factor of the cesium resonance line is small. The He^3 spin oscillator has several merits as compared to the cesium oscillator, of which the most notable are the absence of thermal dependence of the resonant frequency and the absence of shifts with changes in the light intensity. This is due to the fact that the pumping light does not interact directly with the ground state atoms, whose orientation is established by exchange collisions with metastable states.[9] However, such exchange collisions result in a resonant frequency shift $\Delta\nu$ and a change in the resonance linewidth L of the oriented He^3 atoms. The following expressions for $\Delta\nu$ and L are given in ref. 10, derived using the density matrix formalism:

$$\Delta\nu=\frac{2\omega_e\tau(2+7\omega_e^2\tau^2)}{3\pi T(1+\omega_e^2\tau^2)(1+16\omega_e^2\tau^2)}, \tag{3}$$

$$L=\frac{1}{\pi T}\left[1-\frac{5}{9(1+16\omega_e^2\tau^2)}-\frac{4}{9(1+\omega_e^2\tau^2)}\right], \tag{4}$$

where τ and T are the lifetimes of the metastable and ground states with respect to exchange; $\omega_e = -2\mu_B H$; and μ_B is the Bohr magneton. It follows from Eqs. (3) and (4) that $\Delta\nu$ and L decrease with decreasing magnetic field. Theory predicts,[11] and experiments have verified,[12] that significant signal intensities are attained in He^3 in magnetic fields below 10 mOe. These considerations indicate that it is feasible to use the He^3 spin oscillation in weak magnetic fields; in addition to strong signals, smaller frequency shifts are to be expected.

Let us now consider the properties of a system of two-spin oscillators using optically oriented Cs^{133} and He^3 nuclei in a single absorption cell. The introduction into the cell of cesium atoms with vapor pressure of the order of 10^{-5} torr shows essentially no effect on the optical pumping of He^3 at room temperature, since the partial pressure of impurities at which a noticeable decrease of the relaxation time of the metastable state occurs is 10^{-4} torr (ref. 9). Moreover, the presence of cesium in the discharge absorption cell appears to be helpful, since it acts as a getter of the impurities that are released by the walls of the cell during operation.[13] However, the presence of the high-frequency discharge in the cell, which is needed for the formation of the metastable helium atoms, can significantly reduce the degree of orientation of the Cs^{133} atoms due to electron collisions, which decrease the relaxation time; this leads to lower intensities of the resonance signals and to line broadening. This situation creates considerable difficulties in the construction of a system of two spin oscillators with simultaneous optical orientation of He^3 and Cs^{133} in the same cell; nevertheless, we have succeeded in building such a system, in which the Cs^{133} spin oscillator is used to stabilize the magnetic field by means of a phase-lock loop (refs. 14 and 15). The signals from the cesium atoms in the discharge are strong enough for this stabilization.

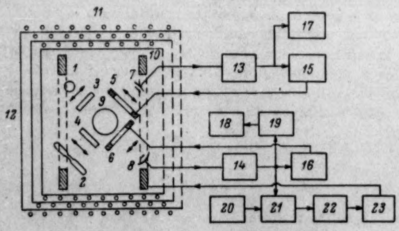

Fig. 2. Block diagram of the experimental arrangement.

EXPERIMENTAL ARRANGEMENT

The experimental arrangement is shown in Fig. 2. To reduce the magnetic field and its inhomogeneities, the entire optical circuit (the spectral pumping lamps 1 and 2; the circular polarizers 3 and 4; the absorption cell 9; and the photodetectors 7 and 8) is placed in a triple cylindrical magnetic shield 12. The outside shield is made of electric steel, and the two inner shields are of permalloy-79 (the inner cylinder is 380 mm in diameter, 500 mm long, and has a wall thickness of 1 mm). Each shield is equipped with a demagnetizing coil 11, fed with current of up to 10 A at standard line frequency. The required magnetic field, whose relative inhomogeneity within the volume of the absorption cell is $2 \cdot 10^{-3}$, is established at the center of the shield by Helmholtz coils 10. The spin oscillators,, which include, in addition to the optical circuits, the amplifiers 13 and 14 (U-2-6) and phase shifters 15 and 16, operate on the cell filled with He^3 at a pressure of 1 torr and Cs^{133} vapor. The pumping lamp of the He^3 spin oscillator is filled with He^4 at a pressure of 7 torr. Both the lamp and the cell are excited by a capacitive electrodeless discharge from a high-frequency (40 MHz) source. In the Cs^{133} spin oscillator the spectral pumping lamp, in which an inductive discharge is excited, is filled with argon at a pressure of 1 torr, and contains cesium vapor. The axes of the radio-frequency coils 5 and 6 are orthogonal to prevent inductive coupling. The oscillation frequencies are determined with the frequency meters 17 and 18 (Ch-3-32); the frequency of the Cs^{133} spin oscillator is measured using a frequency divider 19 (1:1000), which makes the measurements more accurate.

The magnetic field is stabilized by the cesium spin oscillator and a feedback loop, which contains a balanced phase detector 21, a quartz generator 20 (G3-44), an adjustment element 22, and a magnetic field control unit 23. The adjustment element is a proportional integrating filter,[14] which allows us to improve the dynamic characteristics of the magnetic field stabilization system. The phase detector output is an error voltage proportional to the phase difference between the signals from the spin oscillator (the sensor of the magnetic field variations) and from the reference quartz oscillator G3-44. The control voltage from the proportional integrating filter is converted into a current, which produces a correction of the magnetic field in the Helmholtz coils. The accuracy with which the magnetic noise is suppressed in this system can be determined from the coefficient W, which is the ratio of the fluctuations in the spin oscillator frequency caused by this noise with the magnetic field stabilization loop closed and open. As follows from ref. 16, the coefficient W is given by

$$W=\xi\left\{\frac{1+\frac{\Delta^2}{16}\xi^2}{1+\left[(\Delta_1+1)^2-\frac{\Delta}{2}\right]\xi^2+\frac{\Delta^2}{16}\xi^4}\right\}^{1/2}. \qquad (5)$$

Here, we have used the notation

$$\Delta=\frac{8}{\pi}\Omega T_1;\quad \Delta_1=\frac{2}{\pi}\Omega T_2;\quad \xi=\frac{\pi f}{2\Omega},$$

where Ω is the locking band; f is the frequency of the disturbance; T_1 and T_2 are the characteristic time constants of the proportional integrating filter, which in our case are 10 and 11 msec, respectively.

A light filter is used in the He^3 spin generator in front of the photodetector, which effectively attenuates the scattered signal from the optically oriented Cs^{133} atoms. The scattered signal from He^3 is the noise level, and does not affect the operation of the Cs^{133} spin generator and the stabilization scheme.

EXPERIMENTAL RESULTS

The system of two spin oscillators operates in a range of magnetic fields from 4 to 100 mOe. The low value of the magnetic field is limited by the bandwidth of the amplifier of the He^3 feedback loop and by the low Q factor of the magnetic resonance line of the optically oriented Cs^{133} atoms. The upper limit is determined by saturation of the shield material by the stray magnetic field produced by the Helmholtz coils. The residual magnetic field of the shield after high-temperature backing in a hydrogen atmosphere and subsequent demagnetization does not exceed 10 gamma along the cylinder axis. The static shielding factor is 5000. The calculated value of this factor, obtained from the equations of ref. 17, is 8300. The discrepancy between these values is due particularly to the less than ideal shape of the shield (the length should be much larger than the diameter), and to the seams and apertures required in the construction process.

The dynamic shielding factor is evaluated experimentally by comparing the mean-square frequency fluctuations of two spin oscillators with optical pumping of Cs^{133} atoms, one of which operates in the laboratory magnetic field outside the shield, and the other in the magnetic field established inside the shield. The fluctuations of the laboratory magnetic field in a 1 Hz band are attenuated by the shield by a factor of about 100, which is close to the calculated value for the dynamic shielding factor of 130. The maximum amplitude of the magnetic field fluctuations inside the shield does not exceed 0.5 gamma in one second.

The principal characteristic of the operation of the Cs^{133} spin oscillator is the presence of a weak high-frequency discharge in the cell, which not only lowers the intensity of the observed signals but also leads to a frequency shift. The magnitude of this shift varies inversely with the magnetic field and discharge intensity. The phase-frequency characteristics of the cesium spin oscillator, operating in a 15 mOe magnetic field, are shown in Fig. 3 for different discharge intensities. The numbers in brackets indicate the relative discharge intensities measured by the voltage at the electrodes of the absorption cell. The decrease in the slope of the characteristic is related to a broadening of the magnetic resonance line of the optically oriented cesium atoms. At the same time, we observe the shielding of the radio field by the plasma, which partially decreases the radio-frequency line broadening.

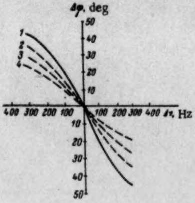

Fig. 3. Phase-frequency characteristics of the spin oscillator with optical pumping of Cs^{133} atoms for different discharge intensities. The discharge intensity is given in relative units. 1) Without discharge; 2) {10}; 3) {20}; 4) {30}.

The low helium pressure (~ 1 torr) causes a small diffusion time τ_{el} of the oriented Cs^{133} atoms to the cell walls. We use a Pyrex cell of volume 50 cm^3, for which τ_d is 3 msec. This relatively short diffusion time, combined with the unresolved hyperfine structure and the radio-frequency and optical broadening, results in a rather broad width of the cesium signal S_x: 1100 Hz for very weak discharges in the cell. The signal-to-noise ratio is about 150 in the 200 kHz bandwidth of the U-2-6 amplifier. The observed signal from Cs^{133} under these conditions is large enough to effectively stabilize the magnetic field inside the shield by means of the phase-lock loop described above. The system also ensures smooth tuning of the magnetic field within the locking range (2 mOe) by tuning the G3-44 reference oscillator. The proportional integrating filter makes it possible to obtain a capture range which in magnitude is close to the locking range. In the stabilization regime the mean-square frequency fluctuation of the cesium spin oscillator does not exceed 0.005 Hz over several seconds, and is determined primarily by the instability of the quartz oscillator. This frequency fluctuation corresponds to a variation in the magnetic field of less than 0.002 gamma.

The stabilization of the magnetic field makes it possible to measure accurately several characteristics of the magnetic resonance of optically oriented He^3 atoms. We obtain a good agreement between the experimental values for $\Delta\nu$ and L and those given by Eqs. (3) and (4). Figure

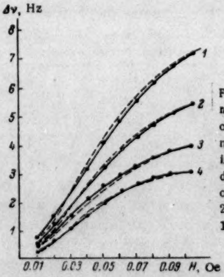

Fig. 4. Dependence of the magnetic resonance linewidth of the optically oriented He^3 ground state atoms on the magnetic field for different discharge intensities in the absorption cell. The dashed curves represent the behavior obtained from Eq. (4). 1) T = 60 msec; 2) T = 80 msec; 3) T = 110 msec; 4) T = 140 msec.

4 shows the behavior of L as a function of the magnetic field obtained at different discharge intensities in the absorption cell. The value of $\Delta\nu$ is determined experimentally by measuring the frequency shift of the He^3 spin oscillator when the cell discharge intensity and the magnetic field are changed. This shift is observed to decrease with decreasing magnetic field and discharge intensity in agreement with Eq. (3), which points out the dominant role of the metastability exchange in the frequency shift of the He^3 spin oscillator.

The spin oscillator with optical pumping of He^3 atoms operates with the magnetic field stabilization loop both closed and open. With the stabilization loop open, the recorded frequency fluctuations of the He^3 and Cs^{133} spin oscillators are completely correlated. These fluctuations are monitored by two Ch3-32 frequency meters with counting accuracy of $\sim 10^{-5}$ Hz of the He^3 frequency and $\sim 10^{-3}$ Hz of the Cs^{133} frequency. Stable operation of the field stabilization system is obtained in a magnetic field of 10 mOe, in which the Q factor of the magnetic resonance line of the optically oriented Cs^{133} atoms is not too low (~ 3). The short-term stability of the He^3 spin generator over a 30 sec interval is better than $5 \cdot 10^{-5}$ Hz with a signal-to-noise ratio of 20 in a 200 kHz bandwidth of the U-2-6 amplifier. A broadening of the He^3 spin generator line is observed with time (the linewidth reaches $5 \cdot 10^{-4}$ Hz ofter one hour of operation), which evidently is caused by electrical noise related to the instability of the supply voltages, changes of the discharge intensities in the pumping lamps and the cell, etc.

To verify this assumption we have calculated theoretically the effect of line noise on the operation of the spin oscillator, and have derived expressions for the linewidth $\Delta\omega$ based on spectral correlation analysis:[18]

$$\Delta\omega = \frac{\pi(n+1)}{\Gamma\left(\frac{1}{n+1}\right)}\left[\frac{A_\varphi}{(4Q\tau_2)^2\,\Gamma(n+2)\sin\frac{\pi}{2}(n+1)}\right]^{\frac{1}{n+1}}, \quad 0<n<1, \qquad (6)$$

$$\Delta\omega = \frac{1}{2Q\tau_2}\left[\frac{2A_\varphi \pi t^{n-1}}{\Gamma(n)\sin\frac{\pi(n-1)}{2}}\right]^{1/2}, \quad 1<n\leqslant 2, \qquad (7)$$

$$\Delta\omega = \frac{1}{2Q}\left\{2A_\varphi\left[\frac{\pi t^{n-1}}{\tau_2^2\Gamma(n)\sin\frac{\pi(n-1)}{2}} - 2\Gamma(3-n)\,t^{n-3}\sin\frac{\pi(n-2)}{2}\right]\right\}^{1/2}, \qquad (8)$$
$$2\leqslant n<3,$$

where $Q = 1/2\omega_0\tau_2$ is the Q factor of the magnetic resonance line; A_φ is a constant characterizing the noise intensity; n is a coefficient which indicates the degree of increase in the line noise at low frequencies; Γ is the gamma function, dependent on n; and t is the observation time satisfying the condition

$$\frac{4}{A_\varphi} > t > \left(\frac{\omega_0^2\tau_2^4}{A_\varphi}\right)^{1/3}. \qquad (9)$$

It is evident from Eqs. (7) and (8) that for $n > 1$ the spin oscillator frequency will drift with time. To evaluate $\Delta\omega$, it is necessary to know the constant A_φ and n, whose measurement entails considerable experimental difficulties. However, it is possible to compute $\Delta\omega$ for the case of line noise related to flicker noise in the semiconductor photodetector. From data in the literature, A_φ can be taken to be of the order of 10^{-9} sec. Then, setting $n = 2$ and substituting the experimental values into Eq. (8), we obtain the following values for the linewidths of the He^3 and Cs^{133} spin oscillators after one hour of operation in a 10 mOe magnetic field: $\sim 10^{-4}$ Hz for He^3 (with T = 30 msec); and ~ 1 Hz for Cs^{133}. Such a large value of $\Delta\omega$ for the cesium spin oscillator is due to a low value of the Q factor of the resonance line, which indicates the necessity of operating in a higher magnetic field. In the case of the He^3 spin oscillator, increasing the magnetic field is undesirable since it results in decreased signal intensity due to a loss of coherence between the ground and metastable states.[11]

CONCLUSION

This work has resulted in the construction of a system of two simultaneously operating spin oscillators with optical pumping of Cs^{133} and He^3 atoms located in the same absorption cell. We have studied the properties of the system in a magnetic field stabilized by a phase-lock on the Cs^{133} spin oscillator. The presently attained short-term frequency stability of the spin oscillators ($5 \cdot 10^{-5}$ Hz in the He^3 and $5 \cdot 10^{-3}$ Hz in Cs^{133}) allows us to reach certain conclusions concerning the potential application of this system in quantum magnetometry and inertial sensing. The long-term stability problem of an optically pumped spin oscillator requires further attention. The experiment shows, and the calculations verify, that the long-term stability of a spin oscillator is limited by nonstationary line noise, which leads to increasing $\Delta\omega$ with time. The study of the noise characteristics of the basic elements of a spin oscillator, i.e., the photodetectors, absorption cells, and pumping lamps, is of considerable importance. The investigation of the noise characteristics of these elements helps in the selection of their optimum operating conditions and in reducing the increase of $\Delta\omega$. As follows from Eqs. (7) and (8), $\Delta\omega$ is inversely proportional to the Q factor of the magnetic resonance line of the optically oriented atoms in the working medium. With decreasing magnetic field the Q factor of the Cs^{133} line decreases and that of the He^3 line increases, which leads to different values for the optimum magnetic field in which the maximum long-term stability is achieved, and in which the smallest frequency shifts of the spin oscillators are obtained with these elements. The nature of these shifts is different in He^3 and Cs^{133}, and thus the error incurred in the measurement of a magnetic field, when this system is used in quantum magnetometry, can be determined. The combination magnetometer with two spin oscillators, He^3 and Cs^{133}, can also be used for simultaneous measurement of the magnetic field with high accuracy (with the He^3 signal) and of the fluctuations of this field with high sensitivity (with the Cs^{133} signal) at the same point in space.

In quantum inertial sensing the system of two spin oscillators with optical pumping of He^3 and Cs^{133} atoms makes it possible to construct a simple, quite sensitive device having all the known qualities of quantum gyroscopes. Under the conditions of the magnetic field stabilized by the automatic control of the Cs^{133} spin oscillator frequency, the angular rotation rate measured by the He^3 spin oscillator frequency will be underestimated by only 1%.

In conclusion we note that in the above system of two spin oscillators with a single absorption cell it is possible to use in place of Cs^{133} also elements such as Rb^{85} and Rb^{87}, and obviously also He^4. The use of the latter in this system would be of considerable interest due to its high gyromagnetic ratio and thermal independence. Operation with these elements would broaden the investigation, and would facilitate the selection of the optimum combination of the nuclear the electron paramagnetic substances for systems with two spin oscillators.

Dynamic magnetic-resonance phenomena

P. S. Kuts and V. S. Mel'nik

Uzhgorod State University

(Submitted March 26, 1973)
Zh. Tekh. Fiz., 44, 185-192 (January 1974)

Dynamic effects are studied in a magnetized gyromagnetic medium that interacts in resonant fashion with a weak magnetic field with transverse polarization; the precession frequency of the magnetic moments varies harmonically in a field of arbitrary amplitude and frequency. Argand diagrams are used to study dynamic hysteresis effects and periodic pulsed amplification of the transverse polarization field by the medium. A microwave-range method using a ferrite is used for an experimental check of the calculation. Physical interpretations of the dynamic phenomena are given.

INTRODUCTION

The problem we consider is closely associated both with resonance gyromagnetic (in particular, ferrite) devices (with variable magnetization) and with the problem of undistorted reproduction of magnetic-resonance signals. The analysis of a number of such devices is based on the notion that the change in the magnetizing field is adiabatic; however, a precise analysis capable of giving the conditions and optimum modes of operation is possible only if a dynamic analysis of the magnetic moments of the working medium is used.

A systematic study of the effect of variable magnetization on the parameters of ferromagnetic resonance has been undertaken earlier by Fabrikov. He obtained an expression[1] which describes dynamic effects in ferrites. We should also note Anderson's study[2] in the field of nuclear magnetic resonance. From the point of view of the spectral analysis of magnetic resonance, the utility of these results is obvious, but the study of the magnetization in time encounters serious difficulties, these being associated with the necessity of summing weakly convergent infinite series. Attempts to make an approximation of the problem that is linear in the magnetizing field (see, e.g., refs. 3, 4) do not solve the problem. We should also note that a theoretical investigation of the effect of rapid linear passage of the resonance region on the shape of the nuclear induction signals was made earlier by Jacobsohn and Wangsness,[5] subject to the condition that the magnetic system is in equilibrium at the beginning of each passage.

In this paper we study dynamic phenomena in magnetic resonance when a gyromagnetic system is harmonically magnetized by a field of arbitrary amplitude and frequency. The state of the medium at the beginning of each period need not be in equilibrium and can be determined by the prehistory.

THEORY

A gyrotropic medium that interacts with a magnetic field can be described by the Landau–Lifshitz equation[6] with a dissipative term in the Bloch–Wangsness form:[4,7]

$$\dot{\mathbf{M}} = -\mu_0 |\gamma| [\mathbf{MH}] + \mathbf{R}, \tag{1}$$

where

$$\mathbf{R} = \frac{\mathbf{e}_1}{T_2}\left(\frac{\chi_{st}}{\mu_0} H_x - M_x\right) + \frac{\mathbf{e}_2}{T_2}\left(\frac{\chi_{st}}{\mu_0} H_y - M_y\right) + \frac{\mathbf{e}_3}{T_1}(M_0 - M_z),$$

where **M** is the magnetization of the medium; **H** is the magnetic field; μ_0 is the permeability of vacuum; $|\gamma|$ is the absolute value of the gyromagnetic ratio; T_1 and T_2 are the longitudinal and transverse relaxation times; χ_{st} is the static susceptibility; M_0 is the equilibrium magnetization in a constant field H_0; and $\mathbf{e}_1$, $\mathbf{e}_2$, $\mathbf{e}_3$, are unit vectors of the rectangular coordinate system x, y, z, respectively. The magnetic field $\mathbf{H} = \mathbf{e}_3[H_0 + h_m(t)] + \mathbf{h}(t)$, which acts inside the medium, will be assumed to be homogeneous. Assume that the variable term in the magnetizing component varies harmonically, $h_m(t) = h_{0m} \cos \Omega t$, and that the weak exciting field is represented in complex form, $\mathbf{h}(t) = \mathbf{h} \exp(i\omega t)$, $\mathbf{h} = \mathbf{e}_1 h_x + \mathbf{e}_2 h_y$, $|\mathbf{h}| \ll H_0, h_{0m}$.

Equation (1) can be solved by successive approximations in the amplitude of the field h(t). Writing the desired solution in the form $\mathbf{M} = \mathbf{M}_0 + \mathbf{m} \exp(i\omega t)$, where $|\mathbf{m}| \ll |\mathbf{M}_0|$, we find that in the steady-state mode $M_x = m_x$, $M_y = m_y$, and $M_z = M_0$, where

$$m_x = im_y. \tag{2}$$

If we replace the transverse components of **h** and **m** by the linear combinations $h_+ = h_x + ih_y$, $m_+ = m_x + im_y$, in a first approximation in the resonant region we have

$$m_+ = \left(\frac{\chi_{st}}{\mu_0} - i\frac{M_0}{\Delta H}\right) \sum_{k,l=-\infty}^{+\infty} (-1)^l \frac{J_{k-l}(q) J_k(q)}{1 + iX_k} \exp(il\Omega t) h_+, \tag{3}$$

where $\Delta H = (\mu_0 |\gamma| T_2)^{-1}$ is the half-width of the resonance curve; $X_k = T_2(\omega - \omega_0 + k\Omega)$, $\omega_0 = \mu_0 |\gamma| H_0$ is the resonant frequency; $q = \mu_0 |\gamma| h_{0m} \Omega^{-1}$ is the modulation index; and $J_k(q)$ is a Bessel function of the first kind. For narrowband media with a large equilibrium magnetization M_0, for which the term χ_{st}/μ_0 can be disregarded, Eq. (3) becomes the familiar Fabrikov expression[1] if the spectrum of the transverse magnetic field contains the one frequency ω.

Expression (2) indicates that the forced oscillations of the transverse magnetization constitute clockwise rotation of the end of the vector **m** about the positive direction of the z axis, which has circular polarization. It is obvious that the oscillation amplitude depends on the nature and direction of the polarization of the exciting field, its proximity to the resonant state, and the parameters of the variable magnetization, namely, the modulation depth and frequency.

We should note that when there is no resonance detuning, $\omega - \omega_0 = 0$, the series in (3) become the sums that

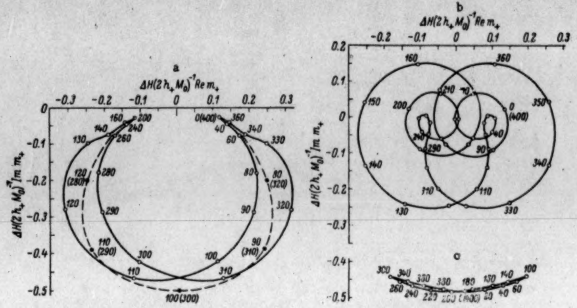

Fig. 1. Argand diagrams for the magnetization $m_+(t)$ with detuning $\omega - \omega_0 = 0$ and various values of the frequencies Ω and amplitudes h_{0m}: a) $\Omega = 0.1T_2^{-1}$, $h_{0m} = 4\Delta H$; b) $\Omega = T_2^{-1}$, $h_{0m} = 9\Delta H$; c) $\Omega = 10T_2^{-1}$, $h_{0m} = 4\Delta H$; the dashed curve is the adiabatic curve ($\Omega \to 0$) for $h_{0m} = 4\Delta H$.

are obtained in ref. 8. For arbitrary detuning, however, this transformation cannot be performed, and hence it becomes necessary to compute them. For this purpose we employed a computer for a broad range of parameters of the problem:

$$\Omega T_2, \ \ (\omega - \omega_0)\, T_2, \text{ and } h_{0m}(\Delta H)^{-1}, \tag{4}$$

which represent the frequency of the modulating field Ω, the detuning $\omega - \omega_0$, and the amplitude h_{0m} respectively, as normalized to the half-width of the resonant absorption curve ΔH.

The time dependence of the transverse magnetization amplitude $m_+(t)$ is given in the form of Argand diagrams,[9] which require that we separate the real and imaginary parts $\mathrm{Re}\, m_+$ and $\mathrm{Im}\, m_+$ in (3). For the separation to be unambiguous we assume, without loss of generality, that the exciting magnetic field is oriented along the x axis, i.e., $h = h_x$. Figure 1 gives the most typical curves as applied to narrow-band gyromagnetic media. The numbers next to the curves denote the time in units of $2\pi \cdot (400\ \Omega)^{-1}$. The dashed curve corresponds to the adiabatic approximation, in which Ω is determined by the instantaneous value of the magnetizing field. Evidently the shape of the dynamic curves differs markedly from the adiabatic curve; on the dashed curve the points referring to different half-periods of the magnetizing field coincide, while on the solid curves they do not. This means that at finite Ω values the amplitude $m_+(t)$ is not a single-valued function of the variable magnetizing field $h_m(t)$, and this is a characteristic feature of hysteresis. We will call this dynamic resonance. Figures 1a and 1c give a quantitative characterization of the delay in $m_+(t)$ relative to its adiabatic values.

At magnetization frequencies comparable to the inverse relaxation time ($\Omega \sim T_2^{-1}$) and at amplitudes h_{0m} that exceed the half-width of the resonance absorption curve ΔH, dynamic hysteresis is accompanied by spiral magnetization oscillations, which, in certain time intervals, go into the upper half-plane of the complex $m_+(t)$, where $\mathrm{Im}\, m_+ > 0$, and, as we will see, the medium is characterized by negative absorption (amplification) of energy of the weak magnetic field $\mathbf{h}(t)$. The number and intensity of the amplification pulses are determined by the parameters of the variable magnetizing field and depend on the amount of resonant detuning. The motion of the magnetization $m_+(t)$ in this case is illustrated by Fig. 1b; evidently, negative-absorption pulses arise after resonance and attenuate rapidly with increasing distance from resonance.

If the medium in question is a small ferrite specimen in a rectangular waveguide, the transmission factor for an electromagnetic wave through this electrodynamical system, in accordance with ref. 10, can be written in the form

$$T = \frac{P}{P_0} = (1 + A\, \mathrm{Im}\, m_+)^2 + (A\, \mathrm{Re}\, m_+)^2, \tag{5}$$

where

$$A = \frac{\lambda_W v}{2\pi ab}\left(\frac{2\pi}{\lambda_W}\sin\frac{\pi}{a}x_0 + \frac{\pi}{a}\cos\frac{\pi}{a}x_0\right)^2 \frac{\mu_0}{2h_+},$$

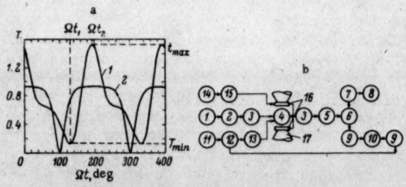

Fig. 2. a) Transmission factor as a function of time for an amplitude $h_{0m} = 4\Delta H$, detuning $\omega - \omega_0 = 0$, and frequencies Ω: 1) T_2^{-1}; 2) $\to 0$; b) block diagram of experimental apparatus: 1) klystron; 2) attenuator; 3) ferrite isolators; 4) working section; 5) microwave detector; 6) coaxial switch; 7) averaging device; 8) recorder; 9) broad-band amplifiers; 10) broad-band oscilloscope; 11) broad-band generator; 12) power amplifier; 13) magnetization-current measuring device; 14) field detuning unit; 15) detuning-current measuring device; 16) detuning coil; 17) constant magnet.

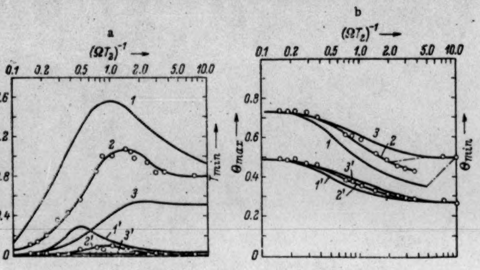

Fig. 3. Amplitude (a) and phase (b) of extrema of transmission factors as a function Ω for $\omega - \omega_0 = 0$: amplitudes h_{0m}: 1, 1') 4ΔH; 2, 2') 2ΔH; 3, 3') ΔH; the experimental points are plotted on the corresponding theoretical curves. Here and in Fig. 4, 1, 2, and 3 refer to the maximum while 1', 2', and 3' refer to the minimum.

and P and P_0 are the transmitted and incident radiation powers; λ_w is the wavelength in the waveguide; v is the volume of the specimen; a and b are the dimensions of the broad and narrow walls of the waveguide; and x_0 is the distance from the narrow wall to the specimen. The coefficient A is independent of the magnetic properties of the specimen being determined by the parameters of the experimental device.

We should note that m_+ appears in (5) as a quantity that is constant in time. Obviously, the substitution of (3), where $m_+ = m_+(t)$, into (5) will be correct if $m_+(t)$ is a slowly varying function of time with respect to the field of frequency ω. This holds in our case if we assume that $\Omega \ll \omega$. Figure 2a shows a typical T = T(t) curve as computed for $A = 2.8 \cdot 10^{-4} (\mu_0/h_+)$; the axes give the values of T_{min}, T_{max}, and the phases Ωt_1, Ωt_2 of the extrema. Curve 2 in the same figure shows the adiabatic relationship. We have investigated the behavior of the extrema of the transmission factor as a function of the parameters of the variable magnetizing field and the detuning. The results are shown in Figs. 3 and 4, where $\Theta_{min} = (\Omega t_1/400)$ and $\Theta_{max} = (\Omega t_2/400)$ are the dimensionless phases of the extrema.

EXPERIMENT

In our investigations, we employ the system shown in Fig. 2b. The gyromagnetic medium is provided by a sphere of yttrium ferrite garnet 0.97 mm in diameter, magnetized to saturation. The specimen with its magnetizing coil is placed inside a segment of rectangular waveguide with a cross section of 23 × 10 mm at the point of circular polarization of the microwave magnetic field. The H_{10} mode is excited in the waveguide; the wavelength in free space is 31 mm. The width of the resonance curve is $2\Delta H = 1.08$, and the saturation magnetization is $M_0 = 1750$ G.

The exciting field is provided by a klystron, whose power level ensures that the crystal detector operates in the square-law mode. The variable magnetizing field is created by a broad-band generator together with a power amplifier. The current in the coil that modulates the field is measured by a VTVM on the basis of the voltage drop across a resistor soldered into the central conductor of the coaxial feed cable. The magnetic saturation of the medium is not disturbed in the process of magnetization. Detuning of the constant magnetizing field from resonance is provided by a stabilized current source; the detuning current is measured with a milliammeter.

We employ the "open-pass" method of recording the ferromagnetic resonance with respect to two channels: The constant component of the transmission factor is measured by a plotter, while the variable component, after amplification, is recorded by a two-beam broad-band oscilloscope, one of whose inputs is fed a voltage that functions as a reference voltage in phase measurements. The electrical lengths of the signal and reference circuits are the same, and the phase shift between the reference voltage and the current in the coil with the specimen, resulting from the reactive nature of the magnetization circuits, is taken into account. We measure the amplitudes and phases of the extrema of the transmission factor T(t), as shown in Fig. 2a. The results are shown by the points in Figs. 3 and 4. The relative errors in the amplitude measurements are 6%; for the phase measurements they are 7%.

RESULTS AND DISCUSSION

As can be seen from Figs. 3 and 4, the theoretical results are in satisfactory agreement with the experimental data. The curves reflect quantitatively the dynamics of the absorption by the medium of the energy of a magnetic field of frequency ω in a specific electrodynamic system (waveguide with ferrite), and make it possible to analyze the above phenomena.

To consider the delay in the response of the medium to the variable magnetizing field in relatively pure form, let us consider the case of zero detuning ($\omega - \omega_0 = 0$) and low field amplitudes, e.g., $h_{0m} = \Delta H$ (Fig. 3). In the low-frequency region, where $\Omega \ll T_2^{-1}$ (the relaxation time T_2 will be assumed to be constant), the parameters of the extrema of the transmission factor are close to their adiabatic values. As Ω rises, the phases of the extrema increase monotonically, tending asymptotically to the values

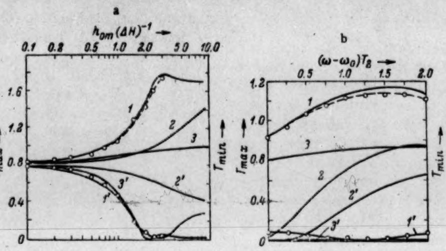

Fig. 4. Extremum values of transmission factor as a function of amplitude h_{0m} for $\omega-\omega_0 = 2T_2^{-1}$ (a) and as a function of the detuning $\omega-\omega_0$ for $h_{0m} = 2\Delta H$ (b). Frequency Ω: 1) T_2^{-1}; 2) $10T_2^{-1}$; 3) $0.1T_2^{-1}$.

of $3\pi/2$ for the maximum and π for the minimum (Fig. 3b). The swing in the oscillations of the transmission factor ($T_{max} - T_{min}$) drops off beginning with frequencies $\Omega \sim T_2^{-1}$ and tends to zero in the region of large Ω (Fig. 3a).

It is clear that when magnetic resonance is harmonically traversed by a field of arbitrary frequency and low amplitude ($h_{0m} \leq \Delta H$), there is a delay in the phase of the absorption signal relative to the initial value corresponding to adiabatic variation of the field. The limiting delay corresponds to the region of infinitely large Ω and amounts to $\pi/2$. The amplitude of the resonance signal at transmission frequencies comparable to the inverse relaxation time drops, tending to zero for $\Omega \gg T_2^{-1}$.

We should note that for large magnetizing-field amplitudes, $h_{0m} > \Delta H$, the delay in the resonance curve is similar to the case considered above (Fig. 3), but it is accompanied by substantial distortion in the line shape in the region $\Omega \gtrsim T_2^{-1}$, in particular, by attenuating post-resonance oscillations (see, e.g., Fig. 2a).

Figure 4a clearly illustrates the resonance-signal intensity as a function of the amplitude h_{0m} when there is detuning ($\omega-\omega_0 = 2T_2^{-1}$). It can be seen that for all h_{0m} the intensity of the variable component of the absorption for $\Omega = T_2^{-1}$ is always greater than at other frequencies.

Another important dynamic effect is periodic pulse amplification by the magnetized medium of the energy of the transverse polarization field. Let us determine the conditions for this effect to arise. It can be seen from Fig. 3b that for transmission amplitudes $h_{0m} > \Delta H$ the phase–frequency response of the transmission-factor maximum has a discontinuity; the discontinuity point is determined by the value of Ω (as before, T_2 will be assumed to be constant) and depends on the amplitude h_{0m}. Exact values of the parameter $(\Omega T_2)^{-1}$ at which the discontinuities occur were not found computationally, but the regions in which they are located are noted in Fig. 3b by the dot–dash line. The nature of the phase discontinuity is as follows. At some frequency Ω, in addition to the typical adiabatic maximum in the transmission factor whose phase is π, a new dynamic maximum appears, whose value increases with Ω. The instant at which the dynamic maximum exceeds the adiabatic one corresponds to the discontinuity point, since the phase of the maximum that appears will differ. At low magnetizing-field amplitudes the adiabatic maximum goes over smoothly into the dynamic one with increasing Ω, and there is no phase discontinuity.

The dynamic maximum in the transmission factor T ensures that there is amplification ($T_{max} > 1$) (for adequate magnetization depth) in the frequency region $\Omega \sim T_2^{-1}$ (Fig. 3a). The threshold value of the magnetizing field is determined both by Ω and by the resonance detuning. It can be seen from Figs. 3a and 4 that for $\Omega = T_2^{-1}$ and $\omega-\omega_0 = 0$ pulse amplification appears beginning with $h_{0m} = 2\Delta H$, while for $\omega-\omega_0 = 2T_2^{-1}$ and the same frequency it appears beginning with $h_{0m} = 0.8\,\Delta H$. Obviously, the pulse power gain is numerically equal to T_{max}. The way in which it depends on the parameters of the problem is illustrated by the same figure. The repetition frequency of the amplification pulses exceeds the frequency of the magnetizing field by a factor of 2 if the detuning $\omega-\omega_0 = 0$, and is equal to it if $\omega-\omega_0 \geq \mu_0|\gamma|\Delta H$. We should also note that at large longitudinal field amplitudes ($h_{0m} \gg \Delta H$) a packet consisting of several pulses that exceed the level $T = 1$ usually arises after resonance; the pulse intensity decreases rapidly with increasing distance from resonance.

It can be seen from the above that the delay in the response of the medium to a variable magnetizing field is determined by the parameter T_2, which constitutes the memory of earlier precession states of some of the magnetic moments. If a precession state is affected by the field $h_m(t)$ in a slowly varying fashion ($\Omega \ll T_2^{-1}$), the magnetic polarization of the medium is determined by the instantaneous value of this field. Otherwise, the prehistory of the medium affects its behavior. In the particular case of large frequencies in which $\Omega \gg T_2^{-1}$, over a period $2\pi/\Omega$ the magnetization differs very little from its initial value (at $t = 0$) and is determined primarily by resonance detuning (Fig. 1c).

The spiral magnetization oscillations (Fig. 1b) which arise after resonance and, under certain conditions result in amplification of the field of frequency ω, are interpreted by Jacobsohn and Wangsness.[5] Here the oscillations are regarded as beats, which arise from the superposition of the attenuating free intrinsic precession of the magnetization and the forced precession resulting from the variable field that acts instantaneously. What remains, therefore, is to explain the radiation mechanism.

In the resonant state, a system of magnetic moments effectively absorbs the energy of a transverse polarization field. When it departs rapidly from resonance into the weak-absorption region, e.g., as a result of changes in the magnetizing field, the system "remembers" its previous state over a time T_2 and hence the energy stored in resonance can be transmitted to the radiation field when there is a certain phase relationship between the field and the magnetization. By simple operations on the quantity $m_v = m_+ \exp(i\omega t)$ we can see that if the field $\mathbf{h}(t)$ has resonant polarization (clockwise in this case), $\mathrm{Re}\, m_+$ is the magnetization component that oscillates in phase with the field, while $\mathrm{Im}\, m_+$ leads it by an angle $\pi/2$. The theory of magnetic resonance (see, e.g., ref. 11) tells us that if $\mathrm{Im}\ m_+ < 0$ a system of magnetic moments absorbs the energy of a field of frequency ω, while if $\mathrm{Im}\, m_+ > 0$ it radiates. As can be seen from Fig. 1b, the radiation conditions ($\mathrm{Im}\, m_+ > 0$) are established in a pulsed fashion as a result of the beats. Since the curve on the Argand diagram is the trajectory of motion of the end of the vector $\mathbf{m}(t)$ in the coordinate system that rotates with frequency ω, while the field $\mathbf{h}$ is oriented along the $\mathrm{Re}\, m_+$ axis, a phase shift $0 < \varphi < \pi$ between the magnetization and the field corresponds to radiation, while a shift $\pi < \varphi < 2\pi$ corresponds to absorption. Obviously, radiation resulting in pulse amplification of the field of frequency ω is coherent, and a gyromagnetic medium is not in an inverted state in this case, since $M_z \approx M_0$.

CONCLUSIONS

In this paper we have given an analysis of effects resulting from the magnetization dynamics of a gyromagnetic medium: resonance hysteresis and the associated pulse periodic amplification of the transverse polarization field. The solution of the problem is given in the form of Argand diagrams, which illustrate the motion of the magnetization in the coordinate system that rotates with frequency ω. The quantities $\mathrm{Re}\, m_+$ and $\mathrm{Im}\, m_+$ make it possible to determine the real and imaginary parts of the magnetic susceptibility of the medium relative to the field of frequency ω at any instant of time. Computer calculations are given in units of the static parameters of the medium and can be applied to any magnetic material (nuclear paramagnetics, e.g., allowing for the sign of γ).

The waveguide-ferrite arrangement used in the experiments is intended to check the theoretical results. However, these results can also be applied to other electrodynamic systems containing gyromagnetic media (e.g., resonators).

Obviously, dynamic effects have a marked influence on the operation of devices based on magnetic resonance in a variable-magnetization mode. The results of this study can also be useful here. Moreover, the possibility of creating new devices that utilize the dynamic phenomena we have described is not ruled out.

The authors thank V. L. Strizhevskii for his interest.

Longitudinal oscillations in an ultrarelativistic electron plasma

D. I. Dzhavakhishvili

Tbilisi State University

(Submitted March 20, 1973; resubmitted June 8, 1973)
Zh. Tekh. Fiz., 44, 193-194 (January 1974)

An investigation is made of longitudinal oscillations excited by a low-density beam of cold electrons in an ultrarelativistic electron plasma with thermal velocities of the order of the velocity of light. The growth rate is found and compared with the case of a nonrelativistic electron plasma.

It is well known[1,2] that both longitudinal and transverse oscillations at high frequencies ($\omega \gg kc$ or $\omega \gtrsim kc$, where ω is the frequency and k is the wave number) can propagate in an ultrarelativistic electron plasma containing particles with thermal energies appreciably higher than their rest energies ($T_0 \gg mc^2$, where T_0 is the temperature in energy units and m is the rest mass of an electron). These waves are not damped[2] since their phase velocity is greater than the velocity of light. In addition there are weakly damped longitudinal electromagnetic oscillations[2] with $V_f = \omega/k \lesssim c$.

It is also obvious that the passage of a beam of nonrelativistic electrons with velocities $u \ll c$ through such a plasma cannot lead to an instability of the high-frequency oscillations referred to above. The shortwave branch ($\omega \ll kc$) of the longitudinal and transverse oscillations cannot exist because of the strong shielding of the waves in the plasma.[2] We show, however, that it is possible to excite longitudinal oscillations with a frequency lower than kc in a hot electron plasma by a cold electron beam ($T_1 \ll mc^2$, where T_1 is the temperature of the beam electrons) having a beam velocity $u \ll c$ and a small spread in thermal velocities [$\omega - \mathbf{ku} \gg kv_1$, where $v_1 = (T_1/m)^{1/2}$ is the thermal velocity of the beam particles].

By using the expression for the longitudinal dielectric constant of an electron plasma[1] we obtain the dispersion relation for the beam–plasma system within the limits indicated above:

$$1+\frac{\omega_0^2}{\lambda k^2c^2}\left[1+\frac{i\pi\omega}{2kc}\right]-\frac{\alpha\omega_0^2}{(\omega-\mathbf{ku})^2}=0, \tag{1}$$

where $\omega_0 = (4\pi e^2 n_0/m)^{1/2}$ is the plasma frequency of the electrons, $\alpha = n_1/n_2$ is the ratio of the electron density in the beam to that of the plasma ($\alpha \ll 1$), and $\lambda = T_0/(mc^2)$ is a dimensionless number ($\lambda \gg 1$).

By discarding the small imaginary part of (1) we find the spectrum of the oscillations excited by the beam

$$\omega=\mathbf{ku}-\frac{\alpha^{1/2}\omega_0}{\left(1+\frac{1}{k^2d_0^2}\right)^{1/2}}, \tag{2}$$

where

$$d_0=\left(\frac{T_0}{4\pi e^2 n_0}\right)^{1/2}$$

is the Debye length of the plasma electrons.

It is clear that (2) is an unstable solution since the phase velocity of the wave becomes smaller than the beam velocity. An instability of this type is discussed in ref. 3, for example.

The growth rate of the oscillations determined by Eq. (2) is given by

$$\gamma=\frac{\pi}{4}\frac{\alpha^{1/2}\lambda^{1/2}}{(1+k^2d_0^2)^{3/2}}\left\{\mathbf{ku}-\frac{kc\alpha^{1/2}\lambda^{1/2}}{(1+k^2d_0^2)^{1/2}}\right\}. \tag{3}$$

Instabilities can arise only when $u > u_{cr}$, where

$$u_{cr}=\frac{\alpha^{1/2}\lambda^{1/2}}{\cos\theta}\frac{c}{(1+k^2d_0^2)^{1/2}}, \tag{4}$$

and θ is the angle between **k** and **u**.

In contrast with ref. 3, where the small parameter α ($\alpha \ll 1$) is arbitrary, in the present case it is necessary to restrict α by the condition

$$\alpha<\left(\frac{u}{c}\right)^{1/2}\frac{1+k^2d_0^2}{\lambda}. \tag{5}$$

For longwave oscillations ($kd_0 \ll 1$)

$$u_{cr}\approx\frac{\alpha^{1/2}\lambda^{1/2}}{\cos\theta}c,\quad \gamma\approx\frac{\pi}{4}\alpha^{1/2}\lambda^{1/2}ku\cos\theta \tag{6}$$

and it is clear that the critical value of the beam velocity is appreciably larger than the result given in ref. 3, and γ is larger by $\lambda^{1/2}$ for the same value of α.

It follows from (3) and (4) that for short waves ($kd_0 \gg 1$)

$$u_{cr}\approx\frac{\alpha^{1/2}\omega_0}{k\cos\theta},\quad \gamma\approx\frac{\pi}{4}\frac{\alpha^{1/2}u\omega_0\cos\theta}{ck^2d_0^2}. \tag{7}$$

It is clear that u_{cr} is now of the same order of magnitude as in ref. 3, but γ is much smaller for a fixed α.

It is easy to see that if the beam of electrons passing through the hot electron plasma with the velocity $u \ll c$ was ultrarelativistic ($T_1 \gg mc^2$), the electromagnetic oscillations with $\omega \ll kc$ would be screened.

Finally it should be noted that the instability discussed above does not occur for transverse waves.

The author is indebted to N. L. Tsintsadze for helpful discussion.

Contribution of multiphoton processes to the linear dielectric constant

V. A. Bushuev and R. N. Kuz'min

M. V. Lomonosov Moscow State University

(Submitted June 12, 1973)
Zh. Tekh. Fiz., 44, 194-196 (January 1974)

Multiphoton corrections to the linear dielectric constant are given; these derive from linear spontaneous inelastic scattering processes described by quadratic and cubic polarizability of the medium. The results of calculations of Raman susceptibility show that the greatest contribution to the imaginary part of the linear dielectric constant is due to Compton scattering on weakly bound electrons in the x-ray band.

In calculating the linear dielectric constant $\varepsilon(\omega \mathbf{k})$ one usually uses first-order perturbation theory. However, Raman parametric, Compton, and other modes of inelastic scattering (IS) can obviously lead to additional attenuation (damping) of the incident wave, and make a contribution to the imaginary part ε''; in accordance with the Kramers–Kronig relation, there must also be a contribution to the real part ε', which determines the refractive index.[1]

In this paper we show that for moderately intense incident waves (pumping) one can introduce an increment to the dielectric constant $\Delta\varepsilon_{IS}(\omega \mathbf{k})$, which acts like an ordinary linear dielectric constant, but whose imaginary part describes the attenuation of the pump due to nondissipative inelastic scattering processes in a solid angle of 4π sr. For simplicity we will confine ourselves to considering multiphoton corrections due only to linear (with respect to pumping intensity) inelastic scattering.

Inelastic scattering can be described phenomenologically by means of the imaginary part of a nonlinear increment to the dielectric constant $\Delta\hat{\varepsilon}_s \equiv \Delta\hat{\varepsilon}(\omega_s \mathbf{k}_s)$, an expression for which is given in ref. 2. Here, ω_s and $\mathbf{k}_s$ are the frequency and wave vector of the wave scattered in the frequency range $d\omega_s$ and the solid angle range $d\Omega_s$. In general, both the quadratic and cubic polarizability of the medium make a contribution to $\Delta\varepsilon_s \sim |E|^2$, where E is the amplitude of the plane monochromatic pumping wave. In a material system both virtual (parametric scattering), and real [Raman[1)]] transitions occur.[3,4]

The nonlinear polarization at the pumping frequency ω is $\Delta\hat{\varepsilon}(\omega \mathbf{k})\mathbf{E}$, where $\Delta\varepsilon$ is easily obtained from the results given in ref. 2 by analogy with $\Delta\varepsilon_s$. It is important to note that $\Delta\varepsilon$ is proportional to the intensity $|E_s|^2$, but in spontaneous inelastic scattering, when the number of scattered photons is much smaller than unity, we can replace $|E_s|^2$ by $2\pi\hbar\omega_s/(n_s V)$, where V is the normalization volume, and n_s is the refractive index calculated using the unperturbed dielectric constant, $\varepsilon^{(0)}(\omega_s \mathbf{k}_s)$. Hence it follows that the overall polarization is proportional to the first power of the pumping field. If the incremental dielectric constant is to have the meaning of a correction to the usual linear dielectric constant, it is necessary to average $\Delta\varepsilon$ over all possible values and directions $\mathbf{k}_s$ and polarizations $\mathbf{e}_s$.

Thus, introducing the next order in perturbation theory leads to an additional polarizability of the medium, which defines its nonlinearity and the intensity of the vacuum fluctuations. In this case, the effective absorption factor of the fundamental wave is

$$\left.\begin{aligned} \mu = \mu^{(0)} + \mu_{IS} = \frac{\omega\varepsilon''}{cn}, \quad \varepsilon = \varepsilon^{(0)} + \Delta\varepsilon_{IS} \\ \Delta\varepsilon_{IS} = \sum_{\mathbf{e}_s} \int (\mathbf{e}\Delta\hat{\varepsilon}\mathbf{e})\, g_s d\omega_s d\Omega_s, \end{aligned}\right\} \qquad (1)$$

where $g_s = V\omega_s^2 n_s^3/(2\pi c)^3$ is the mode density of a single polarization at a frequency ω_s, and for simplicity the medium is assumed to be isotropic and weakly absorbing. The corresponding integrated corss section of inelastic scattering in calculations on a single unit cell is μ_{IS}/n_0, where n_0 is the density of the number of cells.

In the optical band, as a rule $\mu_{IS} \ll \mu^{(0)}$. Thus, according to refs. 5 and 6, due to parametric and Raman scattering processes $\mu_{IS} \sim 10^{-6}$-10^{-7} cm^{-1}. When the pumping frequency is increased in the x-ray band it is easy to show, using the method of calculating solid-state Raman susceptibility developed, for example, in refs. 3 and 7, that the most effective of the inelastic scattering processes is Compton scattering by free and weakly bound electrons.[2)] In the random phase approximation we have

$$(\mathbf{e}\Delta\varepsilon\mathbf{e})'' = -\left(\frac{eq}{m\omega\omega_s}\right)^2 (\mathbf{e}\mathbf{e}_s)^2 |E_s|^2 \operatorname{Im} \frac{1}{\varepsilon^{(0)}(\Omega \mathbf{q})},$$

where $\Omega \equiv \omega - \omega_s$, $\mathbf{q} \equiv \mathbf{k} - \mathbf{k}_s$, and it follows from relations (1) that in like materials the fraction of the absorption due to the Compton effect (more effectively, as is well known, for fairly high q) and the photoelectric effect, described by the dielectric constant $\varepsilon^{(0)''}$, may be of the same order. Thus, in beryllium $\mu^{(0)} \sim \mu_{IS} \sim 0.3$ cm^{-1} in the case of an unpolarized pump at ~ 0.8 Å.

In conclusion we note that the formalism described above is easily generalized to the case of the propagation of x rays in ideal crystals, where the effect of inelastic scattering leads to a certain renormalization of the coefficients of the dynamic theory. A microscopic description of this effect is given in ref. 9.

The authors thank D. N. Klyshko for useful discussion.

[1)] Compton scattering and Brillouin scattering, which are better known in x-ray optics as thermal diffusion scattering, also apply.

[2)] A possible exception is the not yet completely explained anomalously high inelastic scattering cross section of x rays by F centers, observed in ref. 8.

Effect of cathode emission on the threshold for striations

N. A. Vorob'eva, Yu. M. Kagan, V. M. Milenin, and A. Kh. Muradov

A. A. Zhdanov Leningrad State University

(Submitted June 13, 1973)
Zh. Tekh. Fiz., 44, 196-197 (January 1974)

Experimental results showing the influence of cathode emission on the threshold for striations in a helium discharge are reported. Striations of two types can arise, depending on whether the cathode operates in the saturation regime.

Existing theories for striations[1-3] describe the conditions under which the plasma becomes unstable, i.e., they furnish a basis for calculating the threshold for the appearance of striations. In these theories the plasma is assumed to be unbounded, and the threshold current is taken to be the current at which the growth rate of the perturbation, a rate which is governed only by conditions within the plasma, becomes positive. It is assumed that the electrode regions cannot affect the appearance of striations.

Actually, however, in discharge tubes of finite length the threshold currents for the existence of striations can be functions of the length of the tube and the feedback. In several cases striations can be induced by oscillations in the plasma (cathode oscillations, oscillations of the anode fall, etc.).

We report here a study of the threshold for the existence of striations as a function of the cathode emission current. In experiments with a discharge tube 2.8 cm in diameter and 70 cm long, with a tungsten-wire cathode, in helium at pressures from 0.3 to 0.8 torr, we find the threshold discharge currents, i.e., those at which striations arise, for various cathode emission currents.

Figure 1 shows the thresholds for several cathode emission currents. It should be noted that the lowering of the threshold for the appearance of striations which occurs when the cathode emission current is reduced is due to the appearance of striations of a second type, having parameters different from those of the oscillations which arise at high emission currents (when the cathode is in the saturation regime). The striations of this second type have a frequency twice that of the striations of the first type over the same length. Another distinctive feature of these striations is that their amplitude falls off appreciably from the cathode toward the anode (striations of the first type decay toward the cathode).

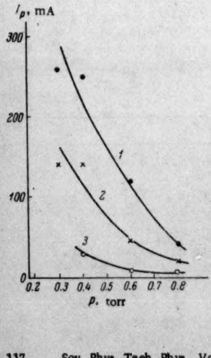

Fig. 1. Lower threshold for the existence of striations as a function of the pressure for various levels of cathode emission (for various cathode heater currents). Heater current I, A: 1) 6.8; 2) 6.3; 3) 5.6.

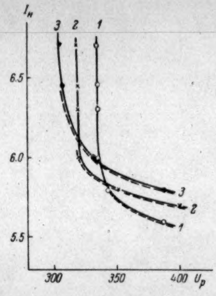

Fig. 2. Voltage drop across the discharge tube as a function of the cathode emission. These experiments are carried out in helium at a pressure of 0.6 torr (the dashed curves show the region in which striations exist). Discharge current I, mA: 1) 10; 2) 20; 3) 50.

We thus find the following picture for the appearance of striations as the cathode emission current is varied.

1. At heater currents at which the cathode is in the saturation regime, striations of the first type arise at a frequency from 5 to 11 kHz (varying with the pressure) and a length of 8-9 cm. The amplitude of these striations falls off toward the cathode.

2. As the cathode emission current is reduced, the striations arise at lower discharge currents, and their frequency varies from 10 to 25 kHz, again varying with the pressure. The amplitude of these striations falls off toward the anode. Increasing the discharge current while holding the heater current constant leads to the appearance of striations of the first type, which can displace the striations of the second type at a sufficiently high current.

Figure 2 shows the potential difference between the electrodes of the discharge tube as a function of the cathode heater current for fixed discharge currents. The points at which striations of the second type appear and the regions over which they exist are indicated. The striations appear at the bend in the characteristics, even though the parameters of the positive column are the same for the entire curve.

Accordingly, calculations of the lower threshold for instabilities in discharges of finite length must take into account the conditions prevailing near the cathode as well as the properties of the plasma which are functions of i, p, and R.

Ionization oscillations in a plasma in the presence of ionizing radiation

B. V. Vainer

Rostov-on-Don State University

(Submitted April 9, 1973; resubmitted June 18, 1973)
Zh. Tekh. Fiz., 44, 197-199 (January 1974)

It is shown that the presence of ionizing radiation in a plasma can cause an instability. Expressions are obtained for the frequency and growth rate of the ionization oscillations.

We consider the self-consistent problem of oscillations of a plane-parallel layer of plasma in which electrons and positive ions move towards the walls as a result of ambipolar diffusion and in which there is a counterflow from the walls into the volume of the plasma of neutral particles resulting from the recombination of electrons and ions on the walls. Ionization can occur within the volume of the plasma through electron impact and the action of radiation.

The equations describing the time variation of the number densities of the particles can be written

$$\frac{\partial n}{\partial t} = D\Delta n - \beta n n_e - In, \tag{1}$$

$$\frac{\partial n_{i,e}}{\partial t} = -\operatorname{div}(\mathbf{v}_{i,e} n_{i,e}) + \beta n n_{i,e} + In, \tag{2}$$

$$\mathbf{v}_{i,e} = b_{i,e}\left(\mathbf{E} - \frac{T_{i,e}}{e}\frac{\nabla n_{i,e}}{n_{i,e}}\right), \tag{3}$$

$$n_i = n_e. \tag{4}$$

In these equations n, n_i, and n_e denote the number densities of neutrals, positive ions, and electrons respectively; D is the coefficient of diffusion of the neutrals; E is the self-consistent electric field; b_e and b_i are the mobilities of the electrons and the positive ions; the term $\beta n n_e$ characterizes the ionization of neutrals by electron impact; and the term In characterizes the ionization of neutrals by radiation.

The plasma is assumed to be significantly nonisothermal, i.e., the temperature of neutrals and ions T_i is assumed to be far below the electron temperature T_e.

In this problem the processes of ambipolar diffusion and diffusion of neutral atoms take place in a dense host neutral gas which does not participate in the formation of ions.

The boundary condition for system (1)-(4) has the form

$$n_i(x = \pm l) = 0, \tag{5}$$

where $2l$ is the thickness of the plasma layer.

The radiation is assumed to be weak, i.e.,

$$I \ll \beta n_i.$$

In the zeroth approximation the stationary solution is

$$n_i^{(0)} = A_i \cos \varkappa x, \tag{6}$$

where

$$\varkappa^2 = \frac{\beta n}{b_i T_e}$$

(n = const to within terms of order T_i/T_e).

Taking terms of the next order into account and utilizing condition (5), we find

$$\varkappa l = \frac{\pi}{2} - \frac{I}{\beta A_i}. \tag{7}$$

Let us now investigate the stability of this system. We seek the solution of Eqs. (1)-(4) in the form

$$n_j(x, t) = n_{0j}(x) + \delta n_j(x, t),$$

where $n_{0j}(x)$ is the stationary solution and δn_j is a harmonic perturbation.

Linearizing system (1)-(4) with respect to small perturbations, we obtain the following equations for the ion and neutral-particle density perturbations

$$-i\omega\delta n_i = b_i T_e \frac{d^2\delta n_i}{dx^2} + \beta n \delta n_i + \beta n_i \delta n + I\delta n, \tag{8}$$

$$-i\omega\delta n = D\frac{d^2\delta n}{dx^2} - \beta n \delta n_i - \beta n_i \delta n - I\delta n. \tag{9}$$

We consider slow oscillations, i.e.,

$$D\varkappa^2, \quad I \ll \omega \ll \beta n \tag{10}$$

and seek the solution of (8)-(9) in the form of an expansion in the small parameter $\omega/\beta n$. We have

$$\delta n_i^{(0)} = d_i \cos \varkappa x,$$

and from (9)

$$\delta n^{(0)} = \frac{\beta n d_i \cos \varkappa x}{i\omega - D\varkappa^2 - I}\left(1 + \frac{\beta A_i \cos \varkappa x}{i\omega - D\varkappa^2 - I}\right). \tag{11}$$

The equation for the first correction to the zeroth approximation has the form

$$\begin{aligned} \frac{d^2\delta n_i^{(1)}}{dx^2} + \varkappa^2\delta n_i^{(1)} = &- \frac{i\omega d_i \cos \varkappa x}{b_i T_e} \\ &- \frac{I}{b_i T_e}\frac{\beta n d_i \cos \varkappa x}{i\omega - D\varkappa^2 - I}\left(1 + \frac{\beta A_i \cos \varkappa x}{i\omega - D\varkappa^2 - I}\right) \\ &- \frac{\beta A_i}{b_i T_e}\frac{\beta n d_i \cos^2 \varkappa x}{i\omega - D\varkappa^2 - I}\left(1 + \frac{\beta A_i \cos \varkappa x}{i\omega - D\varkappa^2 - I}\right). \end{aligned} \tag{12}$$

Solving (12) by variation of parameters and utilizing boundary condition (5) gives the dispersion relation in the form

$$\cos \varkappa l + \frac{1}{\varkappa^2} \int_0^{\pi/2} f(\omega, \tau) \cos \tau d\tau = 0, \tag{13}$$

where $f(\omega, \tau)$ is the right side of Eq. (12).

Using (7), we find the frequency ω' and the growth rate ω''

$$\left.\begin{aligned} \omega' &= \left(\frac{8}{3\pi}\right)^{1/3} \beta (nA_i)^{1/3}, \\ \omega'' &= -\frac{D\varkappa^2}{2} + \frac{n\dot{I}}{\pi A_i}. \end{aligned}\right\} \tag{14}$$

The perturbation will be unstable when

$$I > \frac{\pi A_i D\varkappa^2}{2n}. \tag{15}$$

It should be noted that this instability criterion does not contradict (10), since

$$\frac{n_i}{n} \ll 1.$$

We have thus shown that the presence of ionizing radiation in a weakly ionized plasma may result in an ionization instability. It should also be observed that this instability can appear in a plasma with a different geometry cylindrical.

In conclusion I should like to thank Prof. L. S. Marochnik and the participants in his seminar for their interest.

Plasma confinement in a time-increasing multipole magnetic field

V. G. Padalka and N. S. Repalov

Physicotechnical Institute,
Academy of Sciences of the Ukrainian SSR, Khar'kov

(Submitted October 5, 1972)
Zh. Tekh. Fiz., 44, 199-201 (January 1974)

The motion of plasma particles in a multipole-type magnetic trap is studied when the current producing the magnetic field configuration increases in time. The trajectories of the particles are established and it is shown that the plasma is confined in a narrow region near the separatrix.

Multipole magnetic traps[1] have been intensively studied in recent years. The interest in this magnetic confinement system stems from the fact that the plasma in a multipole magnetic field is stable up to a certain critical magnetic surface. In the magnetohydrodynamic limit this surface is given by the condition[1]

$$\frac{\partial}{\partial\psi}\oint\frac{dl}{H}=0$$

and, in the case of finite ion orbits, by[2]

$$\frac{\partial}{\partial\psi}\oint dl=0\,.$$

As a rule, the current in the rings of a closed multipole trap is induction-excited and the system is filled with plasma by external injection of a plasma jet from a pulsed plasma gun. The mean energy of hydrogen ions captured by the trap[3,4] is 50–100 eV.

The change in the intensity of the multipole magnetic field during the plasma containment time must be taken into account when interpreting the experimental results. The induced electric field E_z, along the axis of the multipole system, leads to drift of the plasma particles along the normals to the magnetic surfaces, the direction of the drift determined by the sign of the time derivative of the current in the current-carrying rings. The plasma density distribution accordingly varies during the containment cycle, and as will be shown below, when the current in the conductors increases the plasma drifts toward the separatrix irrespective of whether the plasma is located inside or outside the separatrix. The plasma is then confined in a region near the separatrix and is also heated.

We consider the motion of charged particles in a nonstationary multipole magnetic field, restricting the discussion to a linear infinite field of quadrupole configuration. Such a field is produced by two linear parallel currents flowing in the same direction. The vector potential of the magnetic field has a single component A_z, directed along the axis of the multipole. In polar coordinates centered on the axis of symmetry of the system A_z can be expressed in the form

$$A_z(r,\varphi,t)=\frac{I(t)}{c}\ln\left[\frac{(r^2+a^2)^2-4ra^2r^2\sin^2\varphi}{a^4}\right], \tag{1}$$

where r is the radial distance, φ the polar angle, $2a$ is the distance between the axes of the current-carrying conductors, and I(t) is the current in the conductor.

The magnetic field produced by the currents has only φ and r components:

$$\left.\begin{aligned}H_\varphi&=-\frac{4Irr^2+a^2\cos2\varphi}{ca^4\quad\psi(r,\varphi)},\\ H_r&=-\frac{4Ir}{ca^4}\frac{a^2\sin2\varphi}{\psi(r,\varphi)},\end{aligned}\right\} \tag{2}$$

where

$$\psi(r,\varphi)=\frac{r^4+2a^2r^2\cos2\varphi+1}{a^4}.$$

It is evident that the equation $\psi(r, \varphi)$ = const defines the magnetic surface of the multipole field.

If the particle Lagrangian

$$L=\frac{m}{2}(\dot r^2+r^2\dot\varphi^2+\dot z^2)+\frac{e}{c}\dot zA_z \tag{3}$$

is independent of the coordinate z and time, during the motion of the particle in such a field the axial component of the generalized momentum is conserved:

$$P_z=m\dot z+\frac{e}{c}A_z \tag{4}$$

as is the kinetic energy:

$$W=\frac{m}{2}(\dot r^2+r^2\dot\varphi^2+\dot z^2). \tag{5}$$

The allowed region for the motion of the particles can be established with the aid of these integrals of motion. It is evident that this region lies between the magnetic surfaces

$$\psi_{1,2}=\left(\frac{r_0^2}{a^2}-1\right)\exp(\pm2\rho_L). \tag{6}$$

Here

$$\rho_L=\frac{mv_0c^2}{2eI}$$

is the effective Larmor radius of the particle, v_0 is its velocity, and r_0 the coordinate of the intersection of the self magnetic surface of the particle with the plane containing the currents. Accordingly, for an adiabatic change of magnetic field ($\omega_H \gg 1/T$, where T is the characteristic time of the change of the magnetic field) one would naturally expect the particles to be displaced along with their confining magnetic surfaces (6).

A detailed picture of the motion of the plasma particles in a nonstationary magnetic field can be obtained by integrating the equations of motion. After averaging over a cyclotron rotation and neglecting drift due to magnetic field gradient, the equations of motion can be written in

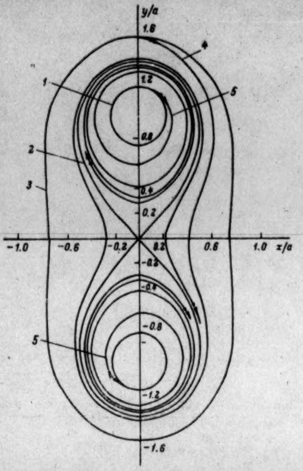

Fig. 1. Topology of magnetic surfaces and trajectories of guiding centers of particles in a multipole magnetic field increasing with time. Magnetic surfaces: 1) $\psi = 0.1936\,(r_0 = 1.2)$; 2) $\psi = 1\,(r_0 = \sqrt{2})$; 3) $\psi = 2.434\,(r_0 = 1.6)$; 4 and 5 denote trajectories of guiding centers of particles ($v_\parallel = 0.1$ cm/sec, T = 10 A/sec).

the form

$$\left.\begin{aligned} \frac{dr}{dt} &= \frac{v_\parallel H_r}{H} + c\frac{EH_\varphi}{H^2}, \\ \frac{d\varphi}{dt} &= \frac{1}{r}\frac{v_\parallel H_\varphi}{H} + \frac{c}{r}\frac{EH_r}{H^2}, \end{aligned}\right\} \tag{7}$$

where

$$H = (H_\varphi^2 + H_r^2)^{1/2}, \quad E = -\frac{1}{c}\frac{\partial A_r}{\partial t}, \quad v_\parallel = \frac{(\mathbf{v}\cdot\mathbf{H})}{H}.$$

Equations (7) are integrated on a digital computer for the case of a linearly varying current. Typical particle trajectories in a magnetic field increasing with time are shown in Fig. 1. It can be seen that irrespective of whether the particle is initially located inside or outside the separatrix ($\psi = 1$), it drifts towards the separatrix as the magnetic field increases.

Thus, a plasma in a time-increasing multipole magnetic field is localized near the separatrix, where it is adiabatically heated and its density increases.

In conclusion we thank O. E. Lysenko and V. I. Panchenko for carrying out the computer calculations.

Reflecting properties of an inhomogeneous anisotropic plasma layer

V. A. Zhivulin and G. I. Makarov

A. A. Zhdanov Leningrad State University

(Submitted May 30, 1973)
Zh. Tekh. Fiz., 44, 201-202 (January 1974)

The transmission of a TM electromagnetic wave through an inhomogeneous layer of a cold plasma with electron polarization in a constant homogeneous magnetic field is analyzed. The layer is unbounded and homogeneous along the y and z axes but has a finite thickness $2x_0$ and is inhomogeneous along the x axis. The electric vector of the incident wave lies in the xz plane. The diagonal component of the relative dielectric permittivity tensor $\varepsilon'_{xx}(x)$ for the plasma has (in the absence of losses) an n-th order zero (n = 2, 4, 6. . .) at the point x = 0. If there are no losses and the constant magnetic field is directed along the y axis, the TM wave is completely shielded by the layer. The shielding effect is not observed for other directions of the magnetic field.

The effect described below has been discussed earlier in ref. 1. That paper considers the transmission of a TM electromagnetic wave through a thin inhomogeneous layer of a cold isotropic plasma with electron polarization. The layer is located in vacuum. It is unbounded and homogeneous along the y and z axes but has a finite thickness $2x_0$ and is inhomogeneous in the x direction. The electron density varies as

$$N(x)=n_0\left[1-(-1)^n\left(\frac{x}{x_0}\right)^n\right] \quad |x|\leqslant x_0,\ n=2,\ 3,\ 4\ldots . \tag{1}$$

According to the results of ref. 1, a TM wave (with electric vector in the xz plane) will not pass through the layer in the absence of any loss mechanism if its frequency ω is equal to the critical value, i.e., the plasma frequency at the point x = 0.

It is of interest to consider the effect of a constant homogeneous magnetic field and this is the subject of the present paper [we take even values of the parameter n in (1) and neglect the effect of the ions]. We consider three particular cases, in which $Y = Y_x$, $Y = Y_y$, or $Y = Y_z$ ($Y = \omega_H/\omega$, where ω_H is the electron gyro-frequency). It is further assumed that the wave is incident from $x < -x_0$, that the electric vector lies in the xz plane, and that the component of the relative dielectric permittivity tensor for the plasma $\varepsilon'_{xx}(x)$ has (in the absence of losses) an n-th order zero at the origin:

$$\varepsilon'_{xx}(x)=0. \tag{2}$$

The problem can be solved by the method of successive approximations (such as has been used, for example, in the study of surface waves in plasma layers[2,3]). The boundary conditions are that the tangential components of the electromagnetic field must be continuous at $x = \pm x_0$. In order to avoid ambiguities (pole in the integrand) we first allow for collisional losses. The effective collision frequency is taken to be constant throughout the layer. The losses are then neglected (the appropriate transition is made in the approximate solution). It then turns out that a TM wave does not penetrate into the region x > 0. However, if $Y = Y_x$ or $Y = Y_z$, then waves of both polarizations occur in the field which penetrates through the layer since a TE wave is excited in the plasma and this passes through the plane x = 0 and there in turn generates a TM wave. If, on the other hand, $Y = Y_y$, the TE wave is not excited by the TM wave and the latter is completely shielded for all angles of incidence (including normal incidence).

The present authors have derived approximate equations (whose accuracy can be determined) for the reflection and transmission coefficients and also for the electromagnetic field components inside the layer (with $Y = Y_x$, $Y = Y_y$, or $Y = Y_z$). They are rather cumbersome and are therefore not given here.

It should be noted in conclusion that in the absence of losses the field inside the layer is a nonanalytical function of x for both the anisotropic and isotropic[1] cases. In particular, the normal component of the electric field becomes infinite at the origin.

Thus the layer we have considered does not allow the transmission of a TM wave if $Y = Y_y$ when condition (2) is satisfied. The shielding effect is not observed for other directions of the constant magnetic field. We have checked this result for $Y = Y_x$ and $Y = Y_z$ and it can anyway easily be seen from what has been said above that the picture is not changed in the intermediate cases (the TM wave will be excited by a TE wave in the region x > 0).

These results can be of interest in a number of practical situations connected with the interaction of an electromagnetic wave with plasmas in which it is important to know the behavior of the field inside the plasma.

Current limiting by self magnetic field in a plasma accelerator

A. G. Korsun

(Submitted December 21, 1972)
Zh. Tekh. Fiz., 44, 202-206 (January 1974)

A study is made of the stationary flow in a coaxial accelerator in which plasma is supplied from the end face of the central electrode. If the discharge current is large a plasma jet is formed in the interelectrode space as a result of the pinch effect. The jet is compressed with increasing current strength and detaches from the outer electrode at a certain limiting current.

We consider the axially symmetric stationary flow of plasma in a high current coaxial accelerator with zero external magnetic field.[1] A completely ionized plasma is supplied to the discharge from the end of the central electrode. The mass flow rate of the accelerated material is G. At large currents I the radial electromagnetic forces compress the flow (pinch effect) and a jet with profile r = R(x) (Fig. 1) is formed in the space between the electrodes. We assume that the transverse componets of flow velocity and current density are much smaller tha the axial values ($v \ll u$, $j_r \ll j_x$), that the jet is long ($R' = \partial R/\partial x \ll 1$), and that the electron and ion temperatures are constant over the cross section [$T_e = T_e(x)$, $T_i = T_i(x)$]. The latter condition holds in the linear pinch.[2-4]

The plasma flow is described by the equations for a continuous medium,[5] which have the following dimensionless form:

$$\left.\begin{aligned}
&\frac{1}{A^2} n(\mathbf{v}\nabla)\mathbf{v} = 2\mathbf{j}\times\mathbf{B} - \frac{1}{2}\nabla p \quad p = nT \quad T = T_e + T_i,\\
&\frac{3}{2}\nabla(p\mathbf{v}) + p\nabla\mathbf{v} = \frac{8}{R_m}\frac{j^2}{\sigma} + \xi\left(\frac{3}{2} j_x \frac{\partial T_e}{\partial x} - T_e \mathbf{j}\frac{\nabla n}{n}\right),\\
&\frac{3}{2}\nabla(p_i\mathbf{v}) + p_i\nabla\mathbf{v} = Q_\Delta = \frac{12\Pi}{R_m}\frac{n^2}{\sigma}(T_e - T_i),\\
&\nabla(n\mathbf{v}) = 0 \quad \mathbf{j} = \frac{1}{2}\nabla\times\mathbf{B} \quad \sigma = T_e^{3/2} \quad T_e = \theta T,\\
&\frac{\partial}{\partial r}\left(\frac{j_x}{\sigma}\right) = \frac{\partial}{\partial x}\left(\frac{j_r}{\sigma}\right) + \frac{1}{2} R_m\left[B\left(\frac{\partial u}{\partial x} + \frac{\partial v}{\partial r}\right) + u\frac{\partial B}{\partial x} + v\frac{\partial B}{\partial r}\right]\\
&- \frac{1}{4}\xi R_m\left[\frac{B}{n^2}\left(\frac{\partial n}{\partial r}\frac{\partial B}{\partial x} - \frac{\partial n}{\partial x}\frac{\partial rB}{r\partial r}\right) + \frac{2B}{rn}\frac{\partial B}{\partial x} + \frac{1}{2n}\frac{\partial T_e}{\partial x}\frac{\partial n}{\partial r}\right].
\end{aligned}\right\} \qquad (1)$$

The dimensional equations are reduced to dimensionless form with the aid of the following scaling: for the linear dimensions and the velocities – the jet radius R_0 and flow velocity U_0 in the initial cross section; the plasma density n, the temperatures T, T_e, T_i, the magnetic induction B, the current density j, and the conductivity σ are respectively scaled in terms of

$$n_0 = \frac{G}{m_i \pi R_0^2 U_0}, \quad T_0 = \frac{\mu I^2 m_i U_0}{8\pi G}, \quad B_0 = \frac{\mu I}{2\pi R_0},$$

$$j_0 = \frac{I}{\pi R_0^2}, \quad \sigma_0 = \sigma^0 T_0^{3/2}.$$

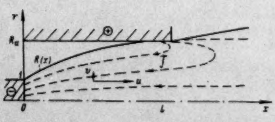

Fig. 1

Here, μ is the permeability, m_i the ions mass, and σ^0 the constant of proportionality in the expression for $\sigma(T_e)$.

Similarity criteria are the Alfvén number A, the exchange parameter ξ (see ref. 6), the magnetic Reynolds number R_m, and the "linear ion"[3] or dimensionless flow rate Π

$$A^2 = \frac{\mu I^2}{4\pi G U_0}, \quad \xi = \frac{m_i I}{eG}, \quad R_m = \mu\sigma_0 U_0 R_0,$$

$$\Pi = \frac{\mu e^2 G}{4\pi m_i^2 U_0} = \frac{A^2}{\xi^2}.$$

If the outer electrode is the anode the exchange parameter $\xi < 0$; for the opposite polarity, $\xi > 0$.

The boundary conditions for the dimensionaless quantities have the following form: at r = Rn = 0, R = 1/R; at r = 0, B = 0; at x = 0, u = 1. It will be shown below that the solution is self-similar when $R' \ll 1$. At x = 0 the solution must satisfy special conditions on n, T, v, j. The conditions on the electromagnetic quantities as the cathode and the anode have little effect on how the parameters in a long jet are distributed because $R_{ma} < 1$ near the cathode and perturbations decay in a distance of the order of unity; near the anode $R_{ma} > 1$ so that perturbations are removed by the flow and decay on route to the cathode in a distance of order R_a/R_{ma} (see Fig. 1).[7]

In order to simplify Eqs. (1) and obtain analytic expressions we utilize a series expansion in the small parameter R'. We note the following three points. First, since all the terms on the right side of the last of Eqs. (1) are of order R' or higher, it follows that in the zeroth approximation j_x/σ is constant over the cross section (as in the linear pinch[2]) but varies along the length of the flow due to the expansion of the jet. Second, because of the weak expansion of the jet, the compressive radial electromagnetic forces are balanced by the pressure in the jet to terms of order R'^2. Accordingly, as in the linear pinch, the following relationship holds:[2,8]

$$T_p \frac{G}{m_i \bar{U}_p} = \frac{\mu I^2}{8\pi}, \qquad (2)$$

where $T_p = T_0 T$ and $\bar{U}_p = U_0 \bar{u}$ are the dimensional temperature and the dimensional mean flow velocity, and T and $\bar{u}$ are the corresponding dimensionless quantities. Third, the requirement of radial equilibrium implies that the force accelerating the flow can be expressed

$$f_x = 2j_r B - \frac{1}{2}\frac{\partial p}{\partial x} = \frac{1}{r^2}\int_0^r \frac{\partial p}{\partial r} r\,dr$$

and, if $p = (1/R^2)\varphi(r/R)$, it follows that

$$f_x = p\frac{R'}{R} = nT\frac{R'}{R}.$$

Consequently, from the equation of motion

$$\frac{1}{A^2}n\left(u\frac{\partial u}{\partial x} + v\frac{\partial u}{\partial r}\right) = f_x$$

for T = T (x) and u (0, r) = 1, we find that the velocity u is constant over the cross section; utilizing (2), we have

$$u = 1 + A^2 \ln R.$$

Thus, the solution of Eqs. (1) in the zeroth approximation has the simple form

$$B = \frac{r}{R^2}, \quad j_x = \frac{1}{R^2}, \quad j_r = j_x\frac{R}{r}R', \quad p = nT = \frac{2}{R^2}\left(1 - \frac{r^2}{R^2}\right),$$
$$T = u = 1 + A^2 \ln R, \quad v = u\frac{r}{R}R'. \tag{3}$$

Despite the fact that the axial electromagnetic force primarily accelerates the peripheral layers of the flow ($j_r B \sim r^2$), while the main mass is concentrated near the axis ($n \sim 1 - r^2/R^2$), the axial velocity is constant over the cross section in the first approximation. Formally, this is a consequence of $p = (1/R^2)\varphi(r/R)$. Actually, the constancy of u comes about because the forces acting on the ions[10] (the electric field, the "electron wind", $-\nabla p_i$, thermal forces) are distributed over the cross section in such a manner that the net force f_x is proportional to n. If $\xi < 0$, the ions are accelerated against the electric field by the "electron wind", the thermal force, and the force $-\nabla p_i$. If $\xi > 0$, the electric field accelerates and the "electron wind" decelerates the ion flow.

If ion heating by electrons is insignificant (the thermal Q_Δ is small), the ions simply cool down as the jet expands:

$$\frac{T_i}{T_i(0)} = (R^2 u)^{-2/3}.$$

If $T_i(0) \ll T_e(0)$, then $T_i \ll T_e = T$, i.e., $\theta = 1$ everywhere. If the term Q_Δ is large, then $T_i = T_e$ i.e., $\theta = 1/2$.

For θ = const the energy equation in conjunction with (3) yields the jet profile

$$x = \frac{1}{8}R_m(1 - \theta\xi)\,\theta^{3/2}\left[(1 + A^2 \ln R)^{5/2}R^2 - 1\right]. \tag{4}$$

The first-order (in R') corrections to the solution for B, j_x, and p have the form:

$$B_1 = -\frac{1}{8}R_m A^2\sigma\frac{r}{R}\left[y + \xi(1-\theta)\frac{R^2}{r^2}y\ln y\right]R', \quad y = 1 - \frac{r^2}{R^2},$$
$$j_{x1} = \frac{1}{8}R_m A^2\sigma\left[1 - 2y + \xi(1-\theta)(\ln y - 1)\right]\frac{R'}{R},$$
$$p_1 = \frac{1}{8}R_m A^2\sigma\left[\frac{1}{4}y(2-3y) + \xi(1-\theta)\left(y\ln y - \frac{1}{2}y - \frac{1}{2}\int_0^y\frac{\ln t}{1-t}\,dt\right)\right].$$

It follows from (4) that increasing I at constant G compresses the jet. The appearance of limiting currents in a high-current accelerator can be described on this basis. If the current is less than the limiting value, the plasma stream touches a certain part of the anode through which the entire current flows. As the current increases toward the limiting value, the jet is compressed and the touched part decreases. The current is then concentrated either at the end of a cylindrically shaped anode or near the critical cross section of an anode shaped as a Laval nozzle.

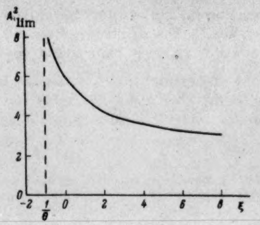

Fig. 2. Variation of limiting value of A^2 with ξ. L = 8, R_a = 2, R^0_m = 0.02; θ = 1.

For a current greater than the limiting value the plasma flow detaches from the anode and a gap with a small plasma concentration appears between the jet and the anode. This leads to an increase in voltage in the near-anode region.[11]

If $u_a \gg 1$, i.e., $A^2 \ln R_a \gg 1$, using $\sigma_0 = (m_i U_0^2/2)^{3/2}A^3$ we obtain the following expression for the limiting value of A^2

$$A^8_{\lim} = \frac{8L}{(1-\theta\xi)\,\theta^{3/2}R^0_m R_a^2(\ln R_a)^{5/2}}, \quad R^0_m = \sigma^0\left(\frac{m_i U_0^2}{2}\right)^{3/2}U_0 R_0, \tag{5}$$

or in dimensional form,

$$\frac{I^8_{\lim}}{G^4}\left(1 - \theta\frac{m_i I_{\lim}}{eG}\right)\left(\frac{m_i}{2}\right)^{3/2}\mu\sigma^0\left(\frac{\mu}{4\pi}\right)^4 = \frac{8L_D}{R^2_{aD}(\ln R_{aD}/R_0)^{5/2}\theta^{3/2}},$$

where L_D and R_{aD} denote the dimensional length and radius of the anode.

The limiting current is independent of U_0 and weakly dependent on R_0. The variation of $A^2_{\lim}$ with ξ is shown in Fig. 2 and with anode dimensions in Fig. 3.

The flow velocity, being dependent only on $A^2 \ln R_a$, reaches its maximum value at limiting currents in an accelerator of given geometry. As can be seen from (5) the increase in flow velocity is due to the increase in the

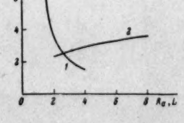

Fig. 3. Variation of limiting value of A^2 with anode dimensions. R^0_m = 0.02, θ = 1, ξ = −4; 1 $A^2_{\lim}$ versus R_a for L = 8; 2 $A^2_{\lim}$ versus L for R_a = 2.

length of the accelerator or in the conductivity due to plasma turbulence.[12] The efficiency of the collisional mechanism of acceleration is improved in both cases.

The author wishes to thank K. V. Leskov for his constant interest in the work and for valuable remarks, and A. I. Morozov for a useful discussion on the results.

Parametric plasma instabilities excited by the sudden application of an electric field

A. B. Kitsenko and K. N. Stepanov
Technical Physics Institute,
Academy of Sciences of the Ukrainian SSR, Khar'kov
(Submitted April 14, 1973)
Zh. Tekh. Fiz., 44, 206-208 (January 1974)

The present work considers the parametric instability in a plasma which occurs on the sudden application of an external electric field $\mathbf{E}(t) = \mathbf{E}_0 \sin \omega_0 t$. The unperturbed distribution function for particles of species α is a doubly periodic function of time with periods $2\pi/\omega_0$ and $2\pi/\omega_\alpha$ (ω_α is the cyclotron frequency for particles of species α). A dispersion equation is obtained for oscillations at a frequency and growth rate much smaller than the pump frequency ω_0. The equation is analyzed for the case of a cold plasma in which the oscillatory velocity of the electrons in the field E is greater than the thermal velocity. It is shown that parametric instabilities are most strongly developed under the resonance conditions $\omega_\pm \approx k_z\bar{u}^{(\alpha)} + m_0\omega_0 + r_0\omega_{Be}$ ($m_0, r_0 = 0, \pm1, \pm2, \ldots$. $\bar{u}^{(\alpha)}$ is the average electron drift speed along the magnetic field and $\omega_\pm$ are the natural frequencies of the longitudinal electron oscillations in the plasma).

In this work we consider the parametric instability in a plasma with an external magnetic field which occurs in the sudden application of an external varying electric field $\mathbf{E}(t) = \mathbf{E}_0 \sin \omega_0 t$. Parametric instability in a plasma is usually considered under conditions in which the field E(t) is applied slowly (adiabatically) at $t = t_0 \to -\infty$. "Sudden" application of the field means that the time taken to establish the field in the region where the instability develops is much smaller than the period of the pump field $2\pi/\omega_0$. It is then possible to get new parametric effects which produce plasma instabilities connected with cyclotron rotation of the particles under the action of the field **E** in the direction perpendicular to the magnetic field $\mathbf{B}_0$ and with the drift of the electrons relative to the ions, parallel to $\mathbf{B}_0$, at some average velocity under the action of the field component E_z parallel to $\mathbf{B}_0$.

A particle with charge e_α and mass m_α, with zero velocity at $t = 0$, will for $t > 0$ move with a velocity $\mathbf{u}^{(\alpha)}(t) = \mathbf{u}_E^{(\alpha)}(t) + \mathbf{u}_B^{(\alpha)}(t)$, where

$$\left.\begin{aligned} u_{Ex,y}^{(\alpha)}(t) &= \frac{e_\alpha}{m_\alpha(\omega_{B\alpha}^2-\omega_0^2)}\left(E_{0x,y}\omega_0\cos\omega_0 t \pm E_{0y,x}\omega_{B\alpha}\sin\omega_0 t\right),\\ u_{Bx,y}^{(\alpha)}(t) &= -u_{Ex,y}^{(\alpha)}(0)\cos\omega_{B\alpha}t \mp u_{Ey,x}^{(\alpha)}(0)\sin\omega_{B\alpha}t,\\ u_{Ez}^{(\alpha)}(t) &= -\bar{u}^{(\alpha)}\cos\omega_0 t,\quad u_{Bz}^{(\alpha)} = \bar{u}^{(\alpha)} \equiv \frac{e_\alpha E_{0z}}{m_\alpha\omega_0}. \end{aligned}\right\} \qquad (1)$$

For adiabatic application of the field $\mathbf{E}(t)$, $\mathbf{u}^{(\alpha)} = \mathbf{u}_E^{(\alpha)}$.

If the plasma particles have a Maxwellian velocity distribution at $t = 0$, the distribution function for $t > 0$ is

$$f_\alpha(\mathbf{v}, t) = \frac{n_{0\alpha}}{(2\pi)^{3/2} v_{T\alpha}^3}\exp\left\{-\frac{[\mathbf{v}-\mathbf{u}^{(\alpha)}(t)]^2}{2v_{T\alpha}^2}\right\}\left(v_{T\alpha} = \sqrt{\frac{T_\alpha}{m_\alpha}}\right). \qquad (2)$$

This distribution is nonstationary (it is a double periodic function of time with periods $2\pi/\omega_0$ and $2\pi/\omega_{B\alpha}$), and therefore various parametric effects are produced. The oscillatory variation in (2) with period $2\pi/\omega_{B\alpha}$ means that the sudden application of the field **E** leads to much richer possibilities in the appearance of resonance effects.

Using the Fourier–Laplace transform we can easily obtain the following equation to describe small oscillations in the plasma:

$$\varphi(\omega) + \sum_{\alpha=e,i}\ \sum_{s,m,l,r=-\infty}^{\infty} J_{s+m}(a_E^{(\alpha)})\, J_m(a_E^{(\alpha)}) \times J_{l+r}(a_B^{(\alpha)})\, J_r(a_B^{(\alpha)})\, e^{-i(s\delta_\alpha+s\pi+l\mu_\alpha)},$$

$$\delta\varepsilon_\alpha(\omega - k_z\bar{u}^{(\alpha)} + m\omega_0 + r\omega_{B\alpha})\,\varphi(\omega - s\omega_0 - l\omega_{B\alpha}) = Q(\omega), \qquad (3)$$

where

$$a_E^{(\alpha)} = \frac{|e_\alpha|}{m_\alpha}\left[\left(\frac{k_z E_{0z}}{\omega_0^2} + \frac{\mathbf{k}_\perp \mathbf{E}_{0\perp}}{\omega_0^2-\omega_{B\alpha}^2}\right)^2 + \frac{\omega_{B\alpha}^2[\mathbf{k}\mathbf{E}_0]_z^2}{\omega_0^2(\omega_0^2-\omega_{B\alpha}^2)^2}\right]^{1/2},$$

$$\operatorname{ctg}\delta_\alpha = \frac{\omega_0}{\omega_{B\alpha}}\left(\frac{k_z E_{0z}}{\omega_0^2} + \frac{\mathbf{k}_\perp\mathbf{E}_{0\perp}}{\omega_0^2-\omega_{B\alpha}^2}\right)\frac{\omega_0^2-\omega_{B\alpha}^2}{[\mathbf{k}\mathbf{E}_0]_z},$$

$$a_B^{(\alpha)} = \frac{1}{\omega_{B\alpha}}\left[k_x u_{Ex}^{(\alpha)}(0) + k_y u_{Ey}^{(\alpha)}(0)\right],$$

$$\mu_\alpha = \operatorname{arc\,tg}\frac{k_y}{k_x} - \operatorname{arc\,tg}\frac{u_{Ex}^{(\alpha)}(0)}{u_{Ey}^{(\alpha)}(0)},$$

$\delta\varepsilon_\alpha(\omega)$ is the contribution of particles of species α to the longitudinal dielectric permittivity of the plasma, $J_n(x)$ is the Bessel function, $\varphi(\omega) = \iint_0^\infty \varphi(\mathbf{r}, t)\exp(i\omega t - i\mathbf{k}\mathbf{r})\,d\omega\,d\mathbf{r}$, $\varphi(\mathbf{r}, t)$ is the potential and $Q(\omega)$ is a quantity proportional to the Fourier transform of the initial perturbation in the distribution function.

For the electron oscillations ($\delta\varepsilon_i \approx 0$), we can easily obtain the dispersion equation $1 + \delta\varepsilon_e(\omega) = 0$ from (3). This equation is identical with the dispersion equation for $\mathbf{E} = 0$, i.e., the high-frequency electron oscillations have the same frequencies as those with $E = 0$ to within an accuracy to the harmonics of the pumping and electron cyclotron frequencies.

We consider the low-frequency oscillations ($\omega_{Bi} \ll |\omega| \ll \omega_0, \omega_{pe}, \omega_{Be}$). In this case the dispersion equation has the form

$$1 + \delta\varepsilon_i(\omega) \sum_{m,r=-\infty}^{\infty} J_m^2(a_E^{(e)})\, J_r^2(a_B^{(e)}) \times [1 + \delta\varepsilon_e(\omega - k_z\bar{u}^{(e)} + m\omega_0 + r\omega_{Be})]^{-1} = 0. \qquad (4)$$

In a strong pumping field when $u^{(e)} \gg v_{Te}$, we can make use of the hydrodynamic expressions $\delta\varepsilon_i \approx -\omega_{pi}^2/\omega^2$ and $\delta\varepsilon_e = -\omega_{pe}^2\cos^2\theta/\omega^2 - \omega_{pe}^2\sin^2\theta/(\omega^2-\omega_{Be}^2)$, where θ is the angle between the wave vector **k** and $\mathbf{B}_0$.

Remembering that $|\omega| \ll \omega_0, \omega_{pe}, \omega_{Be}$, we find from (4) that $\omega = \pm\omega_1$, where

$$\omega_1^2=\omega_{pi}^2\Big[1-J_0^2(a_B^{(e)\prime})J_0^2(a_B^{(e)\prime})-2J_0^2(a_B^{(e)\prime})J_1^2(a_B^{(e)\prime})$$

$$-\sum_{m,r}{}' J_r^2(a_B^{(e)\prime})J_m^2(a_B^{(e)\prime})\frac{\delta\varepsilon_e(m\omega_0+r\omega_{Be}-k_z\bar{u}^{(e)})}{1+\delta\varepsilon_e(m\omega_0+r\omega_{Be}-k_z\bar{u}^{(e)})}\Big]. \qquad (6)$$

The summation here over m and r is from $-\infty$ to ∞ except for $m = 0$ and $r = 0$ and also $m = 0$ and $r = \pm 1$.

Under the resonance condition $m_0\omega_0 + r_0\omega_{Be} - k_z\bar{u}^{(e)} \approx \omega_\pm$, where $\omega_\pm$ are the frequencies of longitudinal electron oscillations in the magnetic field with $\mathbf{E} = 0$,

$$\omega_\pm^2=\frac{1}{2}(\omega_{pe}^2+\omega_{Be}^2)\pm\frac{1}{2}[(\omega_{pe}^2+\omega_{Be}^2)^2-4\omega_{pe}^2\omega_{Be}^2\cos^2\theta]^{1/2},$$

the frequency ω is defined by the expression

$$\omega^2=\frac{1}{2}(\omega_1^2+\delta^2)\pm\frac{1}{2}[(\omega_1^2-\delta^2)^2-4\delta\gamma_0^3]^{1/2}, \qquad (7)$$

where

$$\left.\begin{aligned}\delta&=m_0\omega_0+r_0\omega_{Be}-k_z\bar{u}^{(e)}-\omega_\pm,\\ \gamma_0&=\left[\frac{2\omega_{pi}^2J_{m_0}^2(a_B^{(e)\prime})J_{r_0}^2(a_B^{(e)\prime})}{\delta\varepsilon_e'(\omega_\pm)}\right]^{1/3},\\ \delta\varepsilon_e'(\omega)&=\frac{2\omega_{pe}^2\cos^2\theta}{\omega^3}+\frac{2\omega\omega_{pe}^2\sin^2\theta}{(\omega^2-\omega_{Be}^2)^2},\end{aligned}\right\} \qquad (8)$$

and the quantity ω_1^2 is given by (6) with $m \neq m_0$ and $r \neq r_0$.

Equations (6) and (7) are a generalization of the results for parametric[2] and Buneman[3] instabilities of a plasma in a magnetic field for the case of sudden application of $\mathbf{E}(t)$.

If $\omega_0 \sim \omega_{pe} \sim \omega_{Be}$, the maximum value of the growth rate $\gamma_{max} \sim \gamma_0 \sim \omega_{pe}(m_e/m_i)^{1/3}$ is of the same order of magnitude as for adiabatic application of the field $\mathbf{E}$. The extra sources of instability, in addition to those considered in refs. 1 and 2, are connected with the appearance of a drift of electrons relative to the ions along B_0 with an average velocity $\bar{u}^{(e)}$ when $E_{0z} \neq 0$ and with electron oscillations at a frequency ω_{Be} when $E_{0x,y} \neq 0$. The presence of the electron oscillations means that it is possible to produce parametric excitation if the pumping frequency lies in the range $\min(\omega_{pe}, \omega_{Be}) < \omega_0 < \max(\omega_{pe}, \omega_{Be})$ with $\omega_0 > (\omega_{pe}^2 + \omega_{Be}^2)^{1/2}$. In particular, at low frequencies ($\omega_0 \gg \omega_{pe} > \omega_{Be}$) when $\omega_+ \approx r_0\omega_{Be}$ we get the following expression for the growth rate:

$$\gamma_{max}\approx\omega_{pe}\left[\left(\frac{m_e}{m_i}\right)J_0^2(a_B^{(e)\prime})J_{r0}^2(a_B^{(e)\prime})\right]^{1/3}\left(a_B^{(e)\prime}\sim\frac{\omega_{Be}}{\omega_0}a_B^{(e)\prime}\ll a_B^{(e)\prime}\right). \qquad (9)$$

We note in conclusion that the effects considered here, caused by the initial kick given to the particles by the application of the field $\mathbf{E}$, should also occur in the intermediate case when the time of the transient effects is of the order of the pump period $2\pi/\omega_0$.

Electron repulsion in a time-resolving electron-optical image converter

M. M. Butslov and M. E. Gertsenshtein

(Submitted April 2, 1973)
Zh. Tekh. Fiz., 44, 208-210 (January 1974)

In principle, pulsed time resolving electron-optical image converters can achieve a time resolution of 10^{-14} sec in the case of a faint light signal. Distortions of the transit time from the photocathode to the deflecting system caused by electrostatic repulsion of electrons are evaluated. Comparatively strong signals, corresponding to 10^3 electrons in a pulse of minimum length, are acceptable.

In principle, pulsed electron-optical image converters can achieve a time resolution of 10^{-14} sec for visible light.[1,2] However, there has been no previous analysis of the role of the signal intensity; we consider this question here.

Electrons in a beam formed by a short light pulse are repelled by electrostatic forces; some of the electrons are accelerated while others are retarded, and the net result is that the pulse entering the deflecting system can be spread out. We speak in terms of electrostatic repulsion, rather than the role of the space charge, although these effects are essentially the same. The term "space charge" is usually used in physical electronics in analyzing intense electron beams, either steady-state or with a steady-state component, and usually in the theory of the plane diode.[3,4] In this situation the entire volume near the cathode is filled with electrons. In a pulsed image converter the situation is radically different: A short light pulse of length τ_1 generates a thin "disk," which moves from the cathode to the deflecting system. This disk fills a volume one-millionth that of the diode, so that the equations derived for the diode are not applicable; accordingly, to avoid confusion we will not use the term space charge. The thickness of this disk is always much smaller than its other dimensions. The time required to traverse the entrance stage, from the photocathode to the deflecting system, τ_0, is of the order of 10^{-8} sec and can in principle be reduced to 10^{-9} sec. The disk thickness, according to the equations for uniformly accelerated motion, is proportional to $(\tau_1/\tau_0)^2$ at the photocathode and (τ_1/τ_0) at the deflecting system. Accordingly, the thickness of the disk at the photocathode in the case of a light pulse $\tau_1 \sim 10^{-12}$ sec long is only one-millionth of the distance across the gap, and the thickness at the deflecting system is one-thousandth of this distance.

Repulsion increases the transverse and longitudinal dimensions of the disk; here we will be concerned only with the longitudinal repulsion, which reduces the time resolution of the entrance cascade.

We assume that the motion of the disk is known when there is no electrostatic repulsion, and we assume that there are no magnetic focusing fields. The longitudinal electric field of the disk outside the disk and at its boundary is

$$E' = 2\pi\sigma, \quad \sigma = \frac{eN}{\pi R_\perp^2}, \quad E' = \frac{2eN}{R_\perp^2}, \tag{1}$$

where σ is the surface charge density, N is the number of photoelectrons in the bunch, and $R_\perp$ is the disk radius.

The equations of motion for electrons are

$$\frac{dv}{dt} = \frac{e}{m} E_0 + \frac{e}{m} E'(r, t). \tag{2}$$

Multiplying by v and integrating we find

$$\begin{gathered} v^2 = \frac{2e}{m} U + \frac{2e}{m} \int E'(r, t)\, dr + v_T^2, \\ v_T^2 = \frac{2e}{m} \Delta M_T, \end{gathered} \tag{3}$$

where the integral is evaluated along the electron trajectory, and U is the potential of the accelerating and focusing field. Equation (3) also includes a term describing the energy spread of the photoelectrons. The correction to the velocity is

$$\frac{\delta v}{v} = \frac{1}{2} \left\{ \frac{1}{U_0} \int E'\, dr + \frac{\Delta U_T}{U_0} \right\}, \tag{4}$$

where U_0 is the potential difference between the cathode and the deflecting system.

Using (1), we find the following equation for the disk boundary:

$$\frac{\delta v}{v} = \frac{1}{2} \left\{ \frac{2eN}{U_0} \int \frac{dr}{R_\perp^2(r)} + \frac{\Delta U_T}{U_0} \right\}. \tag{5}$$

All quantities in Eq. (5) are known. As is evident from the derivation, Eq. (5) holds as long as the thickness of the disk is much less than its radius.

In the case of a charge density which is uniform with respect to thickness in the disk, the field varies linearly, so there will be a factor of $1/\sqrt{3}$ involved in calculating the rms velocities.

Our problem is to find the intensity at which the role of repulsion and the role of the energy spread become comparable. The time spread is

$$\frac{\delta\tau}{\tau_0} = -\frac{\delta v}{v}, \quad \frac{\delta\tau}{\tau_0} = \frac{2}{\sqrt{3}} \frac{eN}{U_0} \int \frac{dr}{R_1^2} \simeq \frac{\Delta U_T}{U_0} = 2 \cdot 10^{-5}. \tag{6}$$

Strictly speaking, the equation for $\delta\tau$ is only an approximation; the difference in the transit time is a function of the rate of increase of the velocity. Accordingly, all equations below are approximate.

We consider the simplest and least favorable case, that of transit from a homogeneous field between the photocathode and the deflecting system without focusing; then we can write

$$\begin{gathered} R_\perp = \text{const}, \quad U_0 = Ex_0, \\ \frac{\delta\tau}{\tau_0} = \frac{2}{\sqrt{3}} \frac{eN}{U_0} \int \frac{dr}{R_\perp^2} \cong \frac{eN}{E_0 R_\perp^2}, \quad \delta\tau \sim \tau_1. \end{gathered} \tag{7}$$

With $\tau_0 \sim 10^{-9}$ sec, we have, according to Eq. (6), a tolerable value of $\delta\tau \cong 2 \cdot 10^{-14}$ sec. Assuming $E_0 = 200$ statvolts/cm = 60 kV/cm and $R_1 = 100\,\mu = 10^{-2}$ cm, we find

$$N < \frac{2 \cdot 10^{-5} E_0 R_{\perp}^{2}}{e} \simeq 10^{3} \text{ electrons},$$

i.e., satisfactory intensities; the statistical error in the amplitude is less than 10%. The spot radius must be such that the image of the spot on the screen shifts by at least a spot diameter over the resolution time. Since the spot diameter is a function of many factors, we will use the more customary language of the current density. Equation (7) can be rewritten as

$$\frac{\pi}{\sqrt{3}} \frac{eN}{\delta\tau_1 \pi R_{\perp}^{2}} \sim \frac{E_0}{\tau_0}, \quad \frac{\pi}{\sqrt{3}} j = \frac{E_0}{\tau_0},$$
$$n = \frac{N}{\pi\tau_1 R_{\perp}^{2}}, \quad j = en, \tag{8}$$

where n is the number of electrons from a unit area per second. Assuming $E_0 = 200$ statvolts/cm and $\tau_0 \simeq 10^{-9}$ sec, we find $n \sim 0.2 \cdot 10^{19}$ electrons/(mm^2 · sec) and $j \simeq 0.3$ A/mm^2.

Accordingly, at these intensities, a single pulse $\tau_1 \sim 10^{-14}$ sec long spreads out very little as a result of electrostatic repulsion of electrons. What will happen to a more complex signal? If the length of this complex signal is such that the thickness of the electron disk is less than its diameter, all the equations above for the field remain valid. We construct some imaginary planes corresponding to a time interval τ_1; the distances between these planes increase only because of the electrons between them. Accordingly, the estimates above for the resolution also hold in the case of complex signals. However, when resolution is not the only consideration and times must be measured, the permissible intensities will be lower. Concrete estimates can be obtained from velocity equation (5).

It is important to note that these calculations hold only for paraxial beams in the axisymmetric electron-optical systems currently in use. A fundamental feature of such systems is chromatic aberration,[3] which limits the time resolution;[2] the limitation becomes more severe, the higher the photon energy. Accordingly, in time-resolving image converters it would be desirable to design a special, nonaxisymmetric electron-optics system with compensation for chromatic aberration. These questions lie outside the scope of this note.

Aberrations in a straight ion-optical accelerator

E. I. Gerasimov, A. I. Solnyshkov, and G. V. Tarvid

D. V. Efremov Scientific-Research Institute of Electrophysical Apparatus

(Submitted April 9, 1973)
Zh. Tekh. Fiz., 44, 210-213 (January 1974)

A 150-keV ion-optical accelerator with an ion current of 3 mA is investigated. The beam-parameter is investigated. The beam-parameter measurement system enables us to obtain data on the current-density distribution over the beam radius and phase diagrams in transverse planes in the different regimes of accelerator operation. The causes of distortion in the phase-volume configuration and the change in the current-density distribution in the beam cross section are investigated. The action of nonlinear focusing forces, which leads to a considerable increase in the effective phase volume, is shown to be a decisive factor. It is also possible to form beams with current-density distribution close to equilibrium, using focusing elements with strong spherical aberration.

Recently, in connection with the development of powerful proton linear accelerators, serious consideration has been given to the quality of the ion beam both from the ion source and also at the exit of the straight accelerator used as the injector for the linear accelerator. In order to refine the beam parameters, formation of a charged-particle beam from the plasma in the ion source has been studied.[1] The causes of distortion of the configuration of the transverse phase volume of the ion beam in the accelerating and transporting channels have been investigated. In particular, it has been shown[2] that one of the causes of the increase in effective phase volume is the action of nonlinear Coulomb forces.

In the present study it is experimentally shown that the presence of nonlinear focusing forces in the ion-optical accelerator system strongly distorts the phase-volume configuration and reduces the mean phase density in the beam at the accelerator exit. Investigations have been carried out on an accelerator with proton energies up to 150 keV with a duoplasmatron ion source.[3] To measure the beam characteristics, we use an iris method; the selected part of the beam is observed on a quartz screen. The measurement system enables us to obtain data on the current-density distribution over the beam cross section, the projection of the transverse phase volume onto the xx' plane, and the cross section of the transverse phase volume intersected by the plane $y = y' = 0$, where x, y, and z are Cartesian coordinates, $x' = (dx)/(dz)$, $y' = (dy)/(dz)$, z is the longitudinal coordinate (along the beam axis). For a beam with axial symmetry, with which we are concerned in the accelerator, the distribution function can be represented in coordinates of RR' and $t = R\Theta'$ (R, R' and t are the radius, and the relative radial and azimuthal velocities). Conversion to a cylindrical coordinate system enables us to consider independently the motion of particles with constant angular momentum (Rt = const), where the Liouville theorem holds for each section cut by the plane Rt = const.

The scheme of the ion-optical accelerator system and the potential distribution between the electrodes are given in Fig. 1a. For the measurement of the beam parameters at the accelerator exit it is noted that the nature of the particle distribution over transverse angles (which corresponds to distribution in the plane R = const)

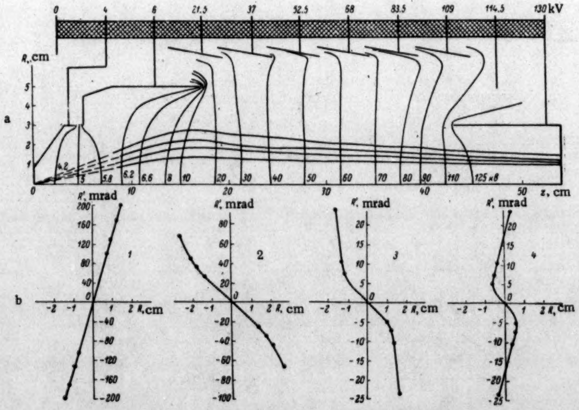

Fig. 1. a) Diagram of ion-optical accelerator system, potential distribution between electrodes, and particle trajectories; b) phase diagrams in RR' plane for different cross sections along the beam path: z, cm: 1) 7.5; 2) 20; 3) 46; 4) 126.

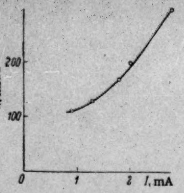

Fig. 2. Dependence of variation in beam divergence angle beyond the extraction electrode on the beam current.

is essentially independent of the geometry of the ion-selection region in the ion source. The geometry of the ion-selection region, which determines the initial beam parameters, is varied over wide limits. Conical and cylindrical expanders are examined, and grids are located on the expander and on the extraction electrode; however, no qualitative change in the nature of the distribution at the accelerator exit is observed.

Therefore, the principal cause determining the observable nature of the distribution can be assumed to be the aberration in the initial part of the ion-optical system, where the transverse dimension of the beam is comparable with the optical-electrode dimensions (Fig. 1a). In the ion source we can select an operational regime with a comparatively low potential at the extraction electrode; owing to the variation in ion density in the penetrating plasma and variation of its form, with increasing arc current there is an almost linear increase in current and divergence angle in the beam beyond the extraction electrode (Fig. 2). Operating in this regime we can vary the beam diameter in the focusing-electrode region. The effect of this parameter on the particle distribution over transverse coordinates and velocities at the accelerator exit can be seen from Fig. 3, which shows how the cross section of the transverse phase volume varies (in coordinates R, R'); also shown is the current-density distribution with increasing arc current, the potentials at the electrodes of the ion-optical system being held constant. From Fig. 3 we see that with increasing beam diameter the boundary of the phase-volume cross section bends and therefore the phase-volume projection increases. There is also a variation in the nature of the current-density distribution over the beam cross section. Figure 4 shows how the phase diagrams and the current-density distribution vary with potential on the focusing electrode. With increasing optical force of the lens (with decreasing potential) the longitudinal spherical aberration decreases. Thus, we can in principle select an operational regime for which the distortion in the phase-volume configuration is a minimum.

From an analysis of phase diagrams and curves of the current-density distribution we see that the existence of nonlinear focusing forces leads to a redistribution of

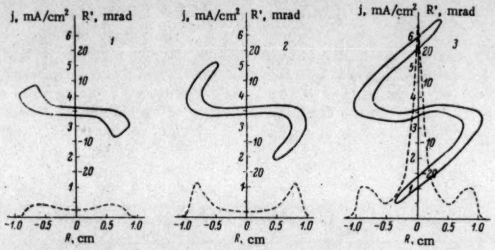

Fig. 3. Cross section of transverse phase volume intersected by the plane Rt = 0 and current-density distribution along the radius for different beam currents. I, mA: 1) 1; 2) 2; 3) 3.

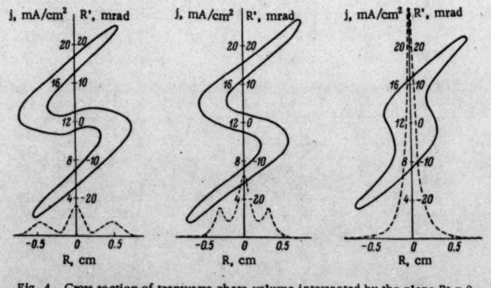

Fig. 4. Cross section of transverse phase volume intersected by the plane Rt = 0 and current-density distribution along the beam radius for different focusing-electrode potentials.

phase density in the charged-particle beam along the acceleration channel and in the transporting channel. This effect enables us to shape the beam at a given location with current-density distribution over the cross section close to equilibrium, which is of great importance in accelerators used, for example, as neutron generators; in this case it is very important to irradiate uniformly the physical target because of the large thermal loads.

The observed nature of the phase-density distribution in the beam is qualitatively independent of the current over a wide range (from 0.1 to 3 mA). This indicates that in the beams being investigated the redistribution of the phase density due to nonlinear Coulomb forces is not a decisive factor; it enables us to neglect the action of space charge, and to investigate particle dynamics in the accelerator by geometric optics under the assumption that we have a point source of particles. The trajectory is constructed on a T-61 trajectory tracer. The results of such constructions and also the phase diagrams in the RR' plane are given in Fig. 1. From these diagrams (Fig. 1b) we see that the phase-volume configuration is distorted because of the nonlinear focusing forces in the ion-optical system, which leads to an increase in the "effective" phase volume.

Coulomb forces have a large effect in injectors of modern linear accelerators,[5] designed for obtaining ion beams with currents of the order of hundreds of milliamperes. Because of the nonlinearity of these forces there is also an increase in the effective phase volume. As a rule, in these accelerators the beam occupies the entire volume inside the accelerating and shaping electrodes; therefore in such a beam, as a result of the presence of aberrations, a large distortion of the phase-volume configuration is possible.

In the present case it has been shown how great these distortions are in an accelerator for comparatively weak currents, where we can neglect the action of Coulomb forces. In high-current accelerators, it is necessary to take account of both factors determining the particle dynamics over the entire accelerating and transporting channels.

Effect of electron reflection on the voltage—current characteristics of a high-voltage, hollow-cathode, glow discharge

Ya. Ya. Udris, V. A. Chernov, and L. G. Guseva

(Submitted December 26, 1972)
Zh. Tekh. Fiz. 44, 213-215 (January 1974)

The ability of a high-voltage, hollow-cathode glow discharge to produce a focused beam of fast electrons, combined with a high discharge stability up to high power levels, is used to produce cold-cathode electron beams at power levels up to tens of kilowatts and higher.[1]

Many workers have emphasized the part played by electrons reflected from the anode in maintaining the high-voltage glow discharge. For example, in ref. 2 the interaction of electrons reflected from the anode with the walls of the discharge tube, and the secondary electrons thereby produced have been advanced as the main mechanism by which the discharge is maintained. According to theoretical results given in ref. 3, where the electron regeneration factors[1)] for the most probable processes are calculated, the regeneration coefficient for reflected electrons is found to be approximately twice that for primary electrons.

Taking into account the fact that in the electron beams of a glow discharge the whole electron flux emitted by the cathode is derived from outside the gas-discharge gap, the part played by the electrons reflected from the anode is reduced to a minimum. Hence, it is possible to estimate the effect of electron reflection on the discharge current. With this aim in mind we plot voltage—current characteristics of the high-voltage gaps of two configurations: A and B. In the first of these the emission of electrons from the anode cavity is cut off, and the flux as a whole is directed to the anode; in the second the electron beam is produced outside the discharge space. Configuration A consists of a plane anode and cathode, placed parallel to one another inside a cylindrical glass tube; the diameter of the electrodes is 100 mm. In configuration B there is a circular opening in the anode, through which the beam is introduced. To focus the electrons in the plane of the output opening, the surface of the cathode, which also has a diameter of 100 mm, is made in the form of a concave sphere of radius of curvature 120 mm. In both cases the cathode material is a low-carbon steel, and the working gas is helium. The pressure is chosen so that the region of the cathode full of potential fills only a small part of the anode cavity over the whole measurement range. Before plotting the characteristics the surface of the cathode is cleaned by a glow discharge.

Particular consideration is given to the fact that in configuration B for the chosen diameter of the opening, the beam electrons do not hit the walls of the anode. Calculations made with the aim of estimating the fraction of electrons incident on the anode due to scattering by helium atoms show that not less than 95% of the beam emerges beyond the limits of the discharge. Measurements of the heat dissipated at the anode confirm this figure. Consequently, in the anode cavity of configuration B there is essentially no ionization by reflected electrons.

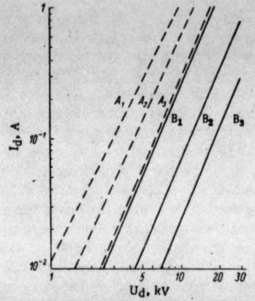

Fig. 1. Voltage—current characteristics of a high-voltage, hollow-cathode glow discharge for two configurations of the gas-discharge gap A and B. The working gas is helium, and the pressure p, torr is: A_1) 0.6; B_1) 0.7; A_2, B_2) 0.4; A_3, B_3) 0.3.

The results of the measurements are shown in Fig. 1. The voltage—current characteristics are described by power functions of the form $I_d = f(p)\,U_d^m$, where I_d and U_d are the current and voltage of the discharge, and $f(p)$ is a function of the pressure p. Plotted on a log—log scale, they are represented by straight lines with a slope m ≃ 2.5 for both configurations. The dashed lines pertain to configuration A, and the solid lines to configuration B. The slope of the characteristics over the chosen range is almost independent of the pressure, which is the parameter of the set of curves shown in Fig. 1.

The elimination of reflected electrons from the discharge space of configuration B causes the B characteristics for the same pressure to lie to the right of the A characteristics. The attaiment of the same discharge current in the B configuration requires a greater relative intensity of such processes as volume ionization by the primary electron flux and ion—electron emission from the cathode than in the A configuration. The reason that the characteristics lie more to the right is that for a given pressure an increase in the voltage leads to an increase in the energy of the ions and neutrals which bombard the cathode, and, consequently, leads to an increase in the ion—electron emission factor. On the other hand, for a fixed discharge voltage, an increase in the pressure leads to an increase in the density of the gas atoms, and hence to an increase in the ions produced by the primary beam. An increase in the pressure therefore, in effect, compensates for the absence of ionization by reflected electrons. How intense the latter is can be seen, for example, from the fact that to maintain a current of 0.3 A in the B configuration one must either increase the voltage from 8.5 to 30 kV, or increase the pressure from 0.3 to 0.75 torr, i.e., by a factor of 2.5.

At the same time, the fact that a high-voltage glow discharge maintains high stability under conditions when there is no reflection of electrons from the anode shows that the process of electron reflection is certainly not necessary for this form of discharge to exist. In the gas-discharge technique a method has been proposed for using known experimental data and behavior to calculate discharge gaps which are similar in configuration but differ in geometrical dimensions. It is also used in relation to gas-discharge electron beams. However, it follows from the results obtained here that when the characteristics of a gap with plane-parallel electrodes are used, without the electrons being removed outside the limits of the discharge space, it is necessary to make a considerable correction when estimating the pressure. Thus, if the beam as a whole is removed from the discharge region, the working pressure will be many times higher than for a similar closed gap.

We can summarize the above results as follows.

1. The results confirm that in a configuration in which the entire electron beam strikes the anode, electron reflection plays an important part in maintaining the high-voltage glow discharge. From the point of view of forming charged particles, necessary to ensure emission from the cathode, the reflected electrons give an effect equivalent to a severalfold increase in the pressure in the discharge space. However, the high-voltage glow discharge does not depend for its existence on electron reflection from the anode.

2. Identical (i.e., with the same slope) voltage–current characteristics have been obtained, for different pressures, for a high-voltage glow discharge with a hollow anode for a discharge gap with solid plane-parallel electrodes and a configuration with an anode which has an opening which enables the electron beam to pass outside the discharge.

3. When making estimates of configurations in which the electron beam is extracted, using experimental data which pertain to the high-voltage discharge in closed plane-parallel configurations, it is necessary to take into account that when the beam is extracted from the discharge space the working pressure should be considerably higher than in a closed gap with similar geometric ratios.

---

1)By the regeneration factor we mean the number of electrons which are reproduced from the cathode of the glow discharge due to processes in the volume and at the electrodes due to an initially emitted electron.

High-power nanosecond electron accelerator with inductive storage

B. M. Koval'chuk, Yu. A. Kotov, and G. A. Mesyats

Atmospheric Optics Institute,
Academy of Sciences of the USSR, Tomsk

(Submitted June 7, 1973)
Zh. Tekh. Fiz., 44, 215-217 (January 1974)

An electron accelerator has been developed in which the primary energy storage is the capacity of a Marks generator (300 kV, $12 \cdot 10^{-3}$ pF). The Marks generator discharges into the inductive energy storage through several parallel copper wires 50 μ in diameter, the inductive storage being the self-inductance of the generator. The wires explode at current maximum. The energy stored in the inductor is transferred to a diode with a multifront cathode. The accelerator yields an electron beam with an electron energy of 600 keV, a current of 5.2 kA, and pulse about 100 nsec long.

High-power nanosecond electron accelerators usually contain two capacitative energy storage units: slow storage and "fast" storage. The first is either a bank of capacitors with a pulse transformer or a Marks generator, while the second takes the form of coaxial lines or strip lines (see ref. 1). The specific energy stored in the capacitative bank is usually 0.01 to 0.1 J/cm^3, and therefore generators of this type with energy up to 10^6 J have dimensions of up to several tens of meters. The largest accelerator dimension is usually determined by the fast reservoir, since the electrical strength of the capacitors used in the slow storage is usually much greater than the insulation strength in the fast storage. The immediate task is then to make the fast storage.

Inductive storage can store energy more efficiently by two or three orders of magnitude. The accelerator voltage pulse is obtained by discharging the capacitor through the inductive storage, and interrupting the current at the instant it reaches the required value (Fig. 1). For example, if the current breaker resistance increases linearly with time, $R_b = at$, and for a load resistance $R_l \gg (L/C_1)^{1/2}$, the breaker terminals show a voltage pulse of length $t_p = (L/a)^{1/2}$ and amplitude

$$U_M = 2U_0 \sqrt{aC_1},$$

where U_0 is the initial voltage on the capacitor. Therefore, to obtain large pulse amplitude and short duration one must increase the rate of growth of the current breaker resistance. Using an exploding wire breaker one obtains the largest rate of growth of resistance with a large number of parallel fine wires (see ref. 2). Assuming that the wire conductance falls off during the progress of the wave of evaporation, at zero time we have

$$\left(\frac{dR_b}{dt}\right)_{t=0} = \frac{16\rho l v}{\pi n d^3},$$

where ρ is the specific resistance; n, *l*, and d are the number of wires, and their length and diameter; and v is the speed of the evaporation wave.

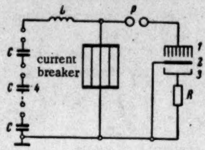

Fig. 1. Circuit of electron accelerator. 1) Multipoint cathode; 2) metal foil anode; 3) Faraday cup; 4) Marks generator, with pulse capacitance $C_1 = C/n$, where n is the number of stages; R is the current measurement shunt.

We have made up an accelerator in which the slow storage is a Marks generator with five stages, with total voltage 350 kV and pulse capacitance $C_1 = 12 \cdot 10^3$ pF. The current breaker is five copper wires 50 μ in diameter. The diode of the accelerator has a multipoint cathode, a foil anode to generate electrons, and a Faraday cup. The inductive storage (L = 6.1 μH) is the self-inductance of the Marks generator discharge circuit. After 0.6 μsec, at a current of 11 kA, the wires explode, the voltage on the inductor L increases, the discharge gap p fires, and a pulse of accelerating voltage is applied to the diode. The electron current pulse has an amplitude of 5.2 kA, the maximum electron energy is 600 keV, and the pulse length is ~100 nsec (Fig. 2).

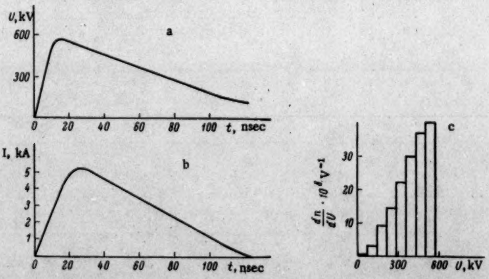

Fig. 2. a) Voltage between the cathode 1 and the anode 2; b) current of electrons in the Faraday cup; c) electron energy spectrum.

The electron energy spectrum is determined from the voltage and current oscillograms, assuming that the electron energy at any time is equal to the voltage difference between the anode and cathode. In this case

$$\frac{dn}{dU}=\frac{i(U)}{e}\frac{dt}{dU},$$

where i(U) is the diode current as a function of the diode voltage, e is the electron charge, and dt/dU is the time derivative of the diode voltage.

Thus, using a current breaker with several fine parallel wires, we have been able to shorten the pulse length by an order of magnitude and to increase the pulse amplitude by almost a factor of 2. The fraction of energy transferred from the capacitor bank to the electron beam is about 20%.

Ionization of a gas-discharge gap by fast electrons

O. B. Evdokimov and A. P. Yalovets

Scientific Research Institute of Electronic Introscopy,
Tomsk Polytechnic Institute
(Submitted February 17, 1973)
Zh. Tekh. Fiz., 44, 217-219 (January 1974)

The distribution of the energy lost in ionization by electrons with initial energies of 0.1-0.5 MeV in the presence of an external accelerating electric field below 2.8 kV/atm · cm is presented. The distribution of the energy lost by the primary electrons when the losses by ionization are much smaller than the increase in energy due to the field is considered.

The ionization of gas-discharge gaps by fast electrons, as shown in refs. 1, 2, etc., enables one to subject the volume discharge to high gas pressure and thereby increase the power of gas switches,[1] and the specific energy emission of electroionization lasers.[2]

The electric field in the gas acts on the electron beam passing through the gas, in particular on the output of bremsstrahlung,[3] and on the ionization distribution produced by it. In turn, the ionization distribution has an effect on the field configuration in the gap, on the electric field strength, and hence on the operation of the corresponding devices. For example, for the operation of an electroionization laser a uniform field in the gap is the most suitable; in practice this can only occur when the ionization produced by the beam is uniform over the volume. To increase the efficiency of the beam, irradiation from the cathode by electrons whose mean free path is close to the value of the interelectrode distance is the optimum.

In this paper we describe results of calculations on the spatial distribution of the energy lost in nitrogen by electrons D with initial energies T_0 from 0.1 to 0.5 MeV in the presence of an electric field.

Because of the smallness of the paths of the secondary particles over this energy range, the distributions of the energy lost and absorbed are practically identical, so the distribution of the energy lost through the energy of formation of an ion pair gives the ionization distribution.

The results of the calculations are valid not only for nitrogen, but for other gases also, in which the effective order number is close to 7 (for example, CO_2 and air). The calculations are made in the continuous slowing approximation by the section model method. It is well known[4] that the continuous slowing approximation is adequate for calculating the distribution of the lost energy (with the exception of depths close to the mean free path, where there are few particles), and the gap model method[5] enables one to describe the transfer of fast electrons in this approximation. In other words, the theoretical approach to this problem is in no way inferior in accuracy to the experimental approach, since the electron interaction cross section for the above-mentioned energies is well known.

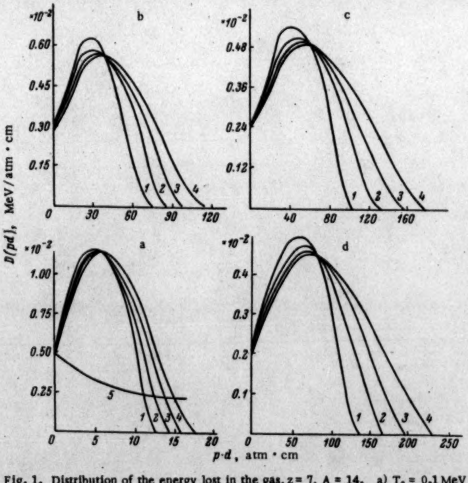

Fig. 1. Distribution of the energy lost in the gas, z = 7, A = 14. a) T_0 = 0.1 MeV for fields eE/p, keV/atm · cm: 1) 0, 2) 0.965, 3) 1.75, 4) 2.82, 5) 30 (nonscattering medium); b) T_0 = 0.3 MeV; eE/p, keV/atm · cm: 1) 0, 2) 0.774, 3) 1.29, 4) 1.8; c) T_0 = 0.4 MeV; eE/p, keV/atm · cm: 1) 0, 2) 774, 3) 1.29, 4) 1.8; d) T_0 = 0.5 MeV; eE/p, keV/atm · cm: 1) 0, 2) 0.7, 3) 0.9, 4) 1.61.

In a previous paper[6] using the section model method we have solved the problem of the transport of fast electrons in a material in the presence of an electric field. The method enables us to calculate the trajectory differential flux I(x, T, cos θ) at a depth x, which is expressed in terms of the energy differential flux φ(x, T, cos θ) by the equation $I = \varphi B$, where $B = B(T)$ are the specific energy losses. In the present work we have calculated the distribution of the energy lost by the electrons D(x) in terms of I(x, T, cos θ) using the following equation:

$$D(x) = 2\pi \int_0^{T_0} dT \int_{-1}^{1} d\cos\theta\, |1 - eEB^{-1}(T)\cos\theta|^{-1}\, I(x,\ T,\ \cos\theta), \tag{1}$$

where T is the kinetic energy of an electron, θ is the angle between the x axis and the direction of the electron momentum, and eE is the force on an electron from the field side.

Figure 1 shows the results of numerical calculations in accelerating fields (irradiation from the cathode side) for different values of eE/p for a single incident electron. It follows from the figure that for fields up to eE/p = 2.8 keV/atm · cm the ionization distribution remains very nonuniform, and only in the region of the extremum is the distribution practically uniform. As E is increased, the value of the electron mean free path increases and also the energy retained by the electron in the gas, for example, the area under the curve of the energy lost for $T_0 = 0.5$ MeV for eE/p = 1.61 keV/atm · cm is greater than that for eE = 0 by a factor of 1.44. This of course only holds in the small-time region, so long as there has been no considerable redistribution of the field.

For high field strengths, when eE > B, the main part of the electrons will be in the accelerating field and will travel along the field. However, not all electrons will behave in this way, since some of them will be scattered at large angles and will find themselves in a retarding electric field. The limiting case occurs when the scattering can be neglected and the energy of the electrons T as a function of the depth is given by the nonlinear equation

$$\frac{dT}{dx} = eE - B(T), \tag{2}$$

then D(x) = B[T(x)]. Curve 5 of Fig. 1a gives the distribution of lost energy obtained in this way for eE/p = 30 keV/atm · cm.

Hence, in a uniform field the lost energy distribution as E increases changes from the curves shown in the figure into D(x) = B[T(x)].

The specific ionization ψ, produced by a beam with a current density j A/cm^2 in a gas at a pressure of p atm, can be calculated in terms of D from the equation ψ (ion pairs · cm^{-3} · sec^{-1}) = $jDe^{-1}\varepsilon^{-1}$, where ε is the mean energy of ion pair formation.

The authors thank G. P. Mesyats for suggesting the problem and for useful discussion, and V. V. Kremnev for fruitful comments.

Ionization and recombination coefficients in a discharge excited by fast electrons

Yu. I. Bychkov, Yu. D. Korolev, and A. P. Khuzeev

Institute of Atmospheric Optics, Siberian Branch,
Academy of Sciences of the USSR

(Submitted November 27, 1972)
Zh. Tekh. Fiz., 44, 219-221 (January 1974)

The development of gas discharge initiated by a short beam of fast electrons is analyzed. Using current oscillograms it is possible to find the ionization and recombination coefficients; these coefficients have been measured in the range of electric fields of interest for ionization lasers.

Gas discharges excited by beams of fast electrons are used for noninductive switching of large current pulses[1,2] and for pumping a new class of lasers called electro-ionization lasers.[3-6] Gas lasers are usually filled with mixtures of CO, N_2, and He in various proportions for which ionization and recombination coefficients are not available; moreover, data on recombination are contradictory even for pure gases.[7] This situation presents serious difficulties, not only in quantitative calculations of discharge parameters, but also in qualitative interpretation of the observed processes. In this note we suggest a method of measuring the ionization and recombination coefficients and present the results obtained in the range of electric fields important for gas lasers.

In these experiments the discharge is started by injecting a nanosecond beam of electrons into a gap in parallel with which there is a capacitance C charged to a voltage U_0. Thus, the initial electron density n_0 in the discharge gap depends on the beam current. The discharge development depends on the condition prevailing in the gap;[8] however, a typical form for high densities $n_0 > 10^{12}$ cm^{-3} is fast settling of the cathode fall[2,4] whose value is a small fraction of the voltage U_0 applied to the gap. The current density j depends on the electron density in the positive column n:

$$j = env_-. \tag{1}$$

Here, e is the electron charge, and v_- is the drift velocity.

If the capacitance C is large enough so that $U(t) = U_0 =$ const during the growth of the discharge, the electron density can be easily found from carrier balance in the positive column:

$$\frac{dn}{dt} = (\alpha - \eta) v_- n - \beta n^2, \tag{2}$$

where α is the first Townsend coefficient, η is the sticking probability, and β is the recombination coefficient.

The solution of (2) has the form

$$n = n_{st} \frac{e^{(\alpha-\eta)v_- t}}{e^{(\alpha-\eta)v_- t} - 1 + \frac{n_{st}}{n_0}}. \tag{3}$$

The steady-state electron density n_{st} is found from the condition $dn/(dt) = 0$,

$$n_{st} = \frac{(\alpha - \eta) v_-}{\beta}. \tag{4}$$

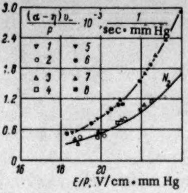

Fig. 1. The function $(\alpha - \eta)v_-/p$ for nitrogen and $CO_2 : N_2 = 1:1$ mixture; p = 4.8 (1), 3.4 (2), 2.4 (3), and 1 (4) atm (nitrogen); 4.5 (5), 3.3 (6), 1.9 (7), and 1 (8) atm (mixture).

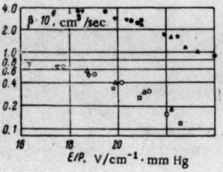

Fig. 2. The function $\beta = \beta(E/p)$ for the same pressures as in Fig. 1.

Equations (3) and (1) describe the oscillograms of current flowing through the gap. By measuring the values of n_{st} and n_0 from the oscillograms it is possible, from the best fit between the theoretical and experimental curves, to determine $(\alpha - \eta)v_-$ and hence, from (4), β.

The validity of this approach has been carefully checked for nitrogen for which α and v_- are known. Figure 1 shows the function

$$\frac{(\alpha - \eta) v_-}{p} = f\left(\frac{E}{p}\right)$$

plotted from the data of ref. 8, and experimental points obtained by the method described above. The figure also shows the variation of the ionization coefficient for the mixture $CO : N_2 = 1:1$. It is evident that the ionization coefficient in nitrogen in the mixture is higher than in pure nitrogen. This is due to the fact that for equal values of E/p the ionization coefficient of pure CO_2 is higher even if the breakdown voltages of both gases are approximately equal. The ionization coefficient of the mixture decreases more rapidly with decreasing E/p, which is probably due to sticking to CO_2 molecules.

Figure 2 shows the functions $\beta = \beta(E/p)$. The value $\beta \sim 10^{-6}$ cm^3/sec indicates that dissociative electron–ion recombination takes place in the discharge.

The authors thank G. A. Mesyats for proposing the topic and for discussion.

Peak current in a cold-cathode magnetron

I. M. Vigdorchik and V. P. Timofeev

Institute of Radio Physics and Electronics,
Academy of Sciences of the Ukrainian SSR, Khar'kov

(Submitted February 19, 1973)
Zh. Tekh. Fiz., 44, 221-223 (January 1974)

The voltage–current characteristics of magnetron diodes with cold secondary emission platinum cathodes are analyzed. It is shown that the anode current is proportional to the Langmuir current. The coefficient of proportionality, which is independent of the geometric parameters of the diodes, is obtained and is approximately equal to 0.08. This relation can be used to calculate the peak anode current in cold-cathode magnetron devices.

The important part played by the secondary-emission properties of the cathode of magnetrons has led to attempts to construct devices which operate entirely with secondary electrons.[1–3] To do this, magnetrons have been constructed (see, for example, ref. 3), which have keep-alive electrodes at the ends of the main (uncooled) cathode; these provide the initial current. Sometimes the main cathode heater is turned off after intense oscillation has started. These designs lead to problems of the thermal balance of the device, which have not so far been solved.

One of the solutions of this problem is to design a magnetron in which the main cathode is cooled (for example, with water), and is made of a material which has a secondary emission coefficient in the cold state $\delta > 1$. A small initial current is produced by a heated cathode, remote from the magnetron interaction space, and placed at the end of the main cathode. This not only avoids electron bombardment of the heated emitter, increasing the useful life or the device, but also provides smooth control of the current injected into the interaction space; under certain conditions the magnetrons can be amplitude modulated.

A study of the effect of the secondary emission coefficient of the material of the main cathode on the operation of magnetron devices, the nature of the voltage–current characteristics, and the value of the oscillatory power gives the following main results. We have been able to establish a relation between the maximum secondary emission coefficient of the cold cathode and the output parameters of the magnetron oscillator. It is found that the voltage–current characteristics of magnetron devices with secondary emission cold cathodes have sharp peaks. An increase in the anode voltage U_a leads to an increase in the anode current up to a certain maximum value I_{am}, followed by a sharp decrease in current to very small values, of the order of the initial thermionic emission current, for values of U_a greater than the critical value.[5] The geometric position of the points of maximum current for different magnetic field intensities H forms the maximum current boundary (MCB). Both in magnetron oscillators and in diodes the maximum current boundary is close to a straight line. The slope and positions of this line depend on the secondary emission coefficient of the material of the main cathode. When the maximum secondary emission coefficient δ_m is increased, the value of I_{am} also increases, and the maximum current boundary shifts towards currents

$$I_{am} = \text{const}\,(\delta_m - 1). \tag{1}$$

When investigating the characteristics of pulsed magnetrons with a cold cathode it is found[6] that I_{am} depends linearly on the product EH (E is the electric field in the anode–cathode gap), and the effect of the geometric parameters of the magnetron device on the maximum anode currents is also considered.[7,8]

The purpose of the present investigation is to study the dependence of the maximum current boundary on the external fields (U_a, H) and the geometric parameters of the tube, and also to investigate the divergence from linear behavior of the maximum current in the case of a magnetron diode with a side thermionic cathode and a cold main cathode of a pure metal, namely, platinum ($\varepsilon_m \approx 1.8$).

Along the axis of a copper anode we place a cathode coated with platinum foil (thickness 0.05 mm) which is cooled with water. At the end of the anode block we place an L-type thermionic cathode. The magnetron diodes are supplied from a pulsed modulator. The anode voltage pulse length is 0.5 μsec, and the pulse frequency is 200 Hz. Inside the sealed-off device a vacuum of the order of 10^{-7} mm is maintained with the help of a getter pump.

A typical curve of the anode current of the pulsed magnetron diode against the anode voltage is shown in Figs. 1 and 2. As can be seen from the figures, the maximum current boundary (the dashed curve) is close to a straight line, as has been previously noted.[5,7]

To determine the functional dependence of the maximum current on the anode voltage the results of the measurements are processed using the method of least squares,[9] and we also draw a graph of I_{am} against U_a on a logarithmic scale (Fig. 3). It can be seen that the maximum anode current of the diode for a given magnetic field is proportional to $U_a^{3/2}$ (the deviation from this relation is less than 5% and may be due to experimental errors):

$$I_{am} = \text{const}\,U_a^{3/2}. \tag{2}$$

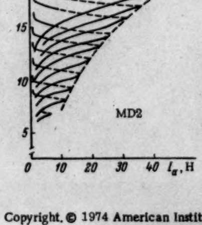

Fig. 1. Voltage–current characteristic of a magnetron diode with a cold main cathode of platinum (D_a = 4.9 mm, and D_k = 2.8 mm). The magnetic field varies from 3660 to 5500 Oe.

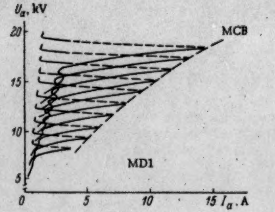

Fig. 2. Voltage–current characteristic of a magnetron diode with a cold main cathode of platinum (D_a = 4 mm, and D_k = 1.65 mm). The magnetic field varies from 3660 to 5670 Oe.

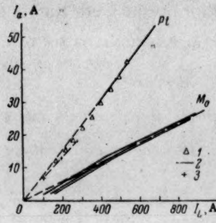

Fig. 4. Maximum anode current against the Langmuir current in magnetron diodes with a cold cathode of platinum and molybdenum. 1) Our data; 2) data from ref. 5; 3) data from ref. 7.

The results obtained can be given a clear physical meaning by relating the value of the limiting current to the Langmuir current, the characteristic parameter of the conventional diode operating under space-charge limited conditions. In fact, when considering the kinematic model of a magnetron diode, for example in ref. 10, it is shown that under space-charge conditions when $H/H_{cr} \rightarrow 1$ (H_{cr} is the critical magnetic field for given U_a), the anode current in a cylindrical magnetron diode under static conditions has a value of approximately $0.08 I_L$, where I_L is the Langmuir current

$$I_L = \frac{14.6 \cdot 10^{-6} U_a^{3/2}}{\frac{D_a}{2\beta^2}} l_a \tag{3}$$

(l_a is the anode length, and β^2 is a function of the ratio of the anode diameter D_a and the cathode diameter D_k).

In magnetron devices with a cold secondary-emission cathode the point of maximum anode current corresponds to operation of the tube with $H/H_{cr} \rightarrow 1$.

By comparing the above considerations and the data of previous investigations [Eqs. (1) and (3)] with the results obtained given by Eq. (2), we can state that the maximum anode current in magnetron diodes with a cold cathode is proportional to the Langmuir current:

$$I_{am} = k(\delta_m - 1) I_L. \tag{4}$$

For comparison we consider the behavior of the curves $I_{am} = f(I_L)$ constructed using the data in refs. 5 and 7, in which pulsed magnetron diodes with cold secondary-emission cathodes of pure metal are investigated. As can be seen from Fig. 4, the maximum current boundaries corresponding to tubes with different geometries lie close to two straight lines, the slope of which is determined by the value of the secondary emission coefficient of the material of the main cathode. The departure from linear behavior in percentage terms on average does not exceed the overall measurement error. The same figure shows the position of the maximum current boundary of one of the magnetron diodes of our geometry with a cold cathode of platinum, and also using the data given in ref. 7. The value of k in all three cases is approximately 0.08.

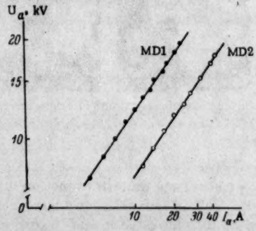

Fig. 3. Maximum current in a logarithmic system of coordinates.

According to preliminary data the relation given by Eq. (4) is also obtained for an anode current close to the maximum, the value of k in this case being less and also not constant, becoming a function of the ratio H/H_{cr}. The physical interpretation of this phenomenon, in our opinion, is that the value of the diffusion flow of electrons to the anode is mainly determined by the magnetic field, i.e., the ratio H/H_{cr}.

The results which have been obtained here enable us to carry out practical calculations of the maximum anode current I_{am} in a magnetron with a cold cathode, if we choose the material of the cathode δ_m and the mode of operation of the device U_a. The error involved according to our data on average is not greater than 10%.

Equation (4) obtained above should be useful in the construction of magnetron oscillators.

Effect of selenium and sulfur on the work function of tungsten

N. V. Volkov, Yu. K. Gus'kov, Z. N. Kononova, and Yu. I. Kostikov

(Submitted April 23, 1973)
Zh. Tekh. Fiz., 44, 224-225 (January 1974)

The effect of selenium and sulfur on the work function of tungsten has been studied. For sulfur a thermionic-emission method based on the total current as a function of the sulfur vapor pressure and the cathode temperature is used. For selenium, a field-emission microscope is used at selenium flux densities of 10^{10}-10^{16} atoms/cm^2 and at tip temperatures of 300-1700°K.

Adsorption of electronegative elements, e.g., oxygen and the halogens, on a tungsten surface significantly increases the work function (see e.g., refs. 1, 2). The only element of the oxygen group which has been used in detailed studies of the effect on the work functions of tungsten and other refractory metals is oxygen. There is definite interest in how other elements of this group (sulfur, selenium, and tellurium) affect the work function of refractory metals. The results of such experiments can be useful for studying the characteristics of thermionic converters.

We report here measurements of the work function of tungsten on which selenium and sulfur are adsorbed. The measurements are carried out with especially pure (99.997%) selenium and sulfur; before being placed in the experimental apparatus, these elements are redistilled in a high oil-free vacuum.

The work function of polycrystalline tungsten is studied in sulfur vapor by a thermionic-emission method on the basis of the total current; these experiments are carried out in a diode with working and protective anodes over the temperature range 1900-2400°K and at sulfur vapor pressures from 10^{-3} to 10^{-1} torr. The vacuum under the working conditions is of the order of 10^{-8} torr. An electric discharge (oil-free) pump is used for the vacuum. The work function measured for the tungsten before the sulfur is injected into the apparatus is 4.5 eV. Figure 1 shows the work function of tungsten as a function of the cathode temperature for various sulfur vapor pressures. We see that the work function of polycrystalline tungsten increases appreciably in sulfur vapor, to 5.3 eV (by 0.8 eV). The sensitivity of our apparatus is not adequate for measuring work functions above 5.3 eV, so we can not determine the ultimate change in the work function. Figure 1 also shows the change in the work function of polycrystalline tungsten at three oxygen pressures, according to the results of Batzies[3] and Greaves and Stickney.[4] A point which seems to deserve some attention is that the change in the tungsten work function corresponding to a change in the sulfur vapor pressure by half an order of magnitude is the same as that observed (at the same cathode temperature) when the oxygen vapor pressure is changed by 1.5 orders of magnitude (over the measured range).

We have studied the effect of selenium on the work function of tungsten in a field-emission microscope at selenium flux densities of 10^{10}-10^{16} atoms/(cm^2 · sec) and at tungsten-tip temperatures of 300-1700°K.

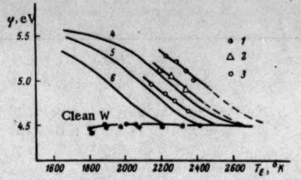

Fig. 1. Work function of tungsten in sulfur vapor as a function of the substrate temperature. Pressure p, torr: 1) 10^{-1}; 2) $5 \cdot 10^{-2}$; 3) 10^{-2}; 4) $1.4 \cdot 10^{-5}$; 5) $5 \cdot 10^{-7}$; 6) 10^{-8} (in an oxygen atmosphere).

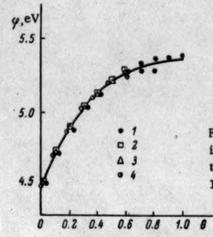

Fig. 2. Work function of tungsten during deposition of selenium for various tip temperatures. T_e, °K: 1) 300; 2) 1065; 3) 1225; 4) 1275.

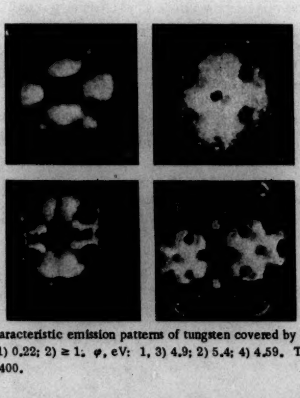

Fig. 3. Characteristic emission patterns of tungsten covered by a selenium film. θ: 1) 0.22; 2) ≥ 1. φ, eV: 1, 3) 4.9; 2) 5.4; 4) 4.59. T_e, °K: 1,2) 300; 3,4) 1400.

The experimental apparatus is evacuated and processed with a discharge pump. The working vacuum is 10^{-9} torr. Figure 2 shows the work function of tungsten found as a function of the selenium coverage. We see that the work function increases significantly as selenium is adsorbed. With a monolayer coverage the work function is increased by 0.9 eV, to 5.4 eV. Figure 3 shows how selenium is adsorbed on various tungsten faces. There is a predominant adsorption near the {112} faces. At coverages greater than a monolayer, small crystals form, but these crystals do not significantly change the work function of the tungsten tip. Selective adsorption of selenium leads to the appearance of large formations or large crystals near {112} faces at tip temperatures in the range 1400-1700°K. These formations reduce the work function of the tungsten tip to 3.8-3.9 eV; this effect is sensitive to the electric field intensity. When the tip is heated, the large crystalline formations vanish and the work function is restored to the value corresponding to the given degree of coverage.

Displacement of ion-current retardation curves in surface ionization in a strong field

N. I. Ionov
A. F. Ioffe Physicotechnical Institute,
Academy of Sciences of the USSR, Leningrad
(Submitted July 4, 1973)
Zh. Tekh Fiz., 44, 225-227 (January 1974)

In weak fields which accelerate ions the discontinuity on the retardation curves corresponds to the contact potential difference of the homogeneous emitter and collector, U_0. In surface ionization in a strong electric field which accelerates ions the quantity $U_0 = (V - \varphi') + (k/e)T\ln(\alpha/A)$ determined from the retardation curves is equal to the difference between the ionization potential of the particles ionized on the emitter surface, V, and the collector work function φ' and is also a function of the degree of ionization α (T is the emitter temperature, A is the pre-exponential factor in the Langmuir–Saha equation, k is the Boltzmann constant, and e is the ion charge). This equation can be used to determine the values of V from the experimental quantities U_0.

The retardation curves for the current of positive ions formed by surface ionization in a strong accelerating electric field are analyzed in ref. 1, but there is an error: The surface potential for ions at the collector is taken into account incorrectly. This error is repeated in ref. 2. In the present note we analyze the problem again, eliminating the error.

Figure 1 shows schematically the potential curve for an ion A^+ at the emitter surface with an external field $\mathcal{E} = 0$ (curve 1), for the case in which the ionization potential of the atom, V, is higher than the work function of the surface, φ. In the region $x > x_{cr}$ (where x_{cr} is the critical charge-exchange distance) the electronic interaction in the system of the adsorbed atom and the absorbent is cut off. In the region $x < x_{cr}$, the interaction between the adsorbed atom and the surface is primarily the chemical binding force; in the region $x > x_{cr}$ it is predominantly the electrostatic force of the polarization interaction. For ions in this latter case the predominant force is the Coulomb force of the mirror image. An external field $\mathcal{E}$ which accelerates ions (curve 2) and the surface field form a potential barrier (curve 3) which peaks at point x_0.

The behavior of the potential energy of ions at the surface of the collector is analogous, but the forces are in the opposite directions.

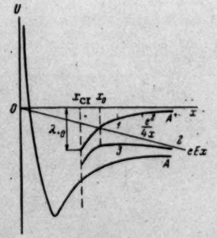

Fig. 1

The external field accelerating ions from the emitter is usually produced by an intermediate grid at a potential of $-U_g$ with respect to the collector. We denote by $\mathcal{E}_c$ the external field at the emitter surface which compensates the surface field throughout the region from $x = \infty$ to x_{cr}, and we consider the motion of ions from the emitter to the collector through the accelerating grid in two cases: 1) $\mathcal{E} < \mathcal{E}_c$ and 2) $\mathcal{E} > \mathcal{E}_c$.

1. $\mathcal{E} < \mathcal{E}_c$. Ions from the emitter surface pass above the potential barrier at x_0 with thermal velocities and move thereafter in the accelerating field between the emitter and the grid. The kinetic energy of the directional motion of the ions during passage through the grid is given by the following equation, which takes account of the contact potential difference:

$$E_1 = e\left(U_g - \mathcal{E}x_0 - \frac{e}{4x_0}\right) - \Delta(x_0) + e(\varphi_g - \varphi)$$

$$= e(U_g - \sqrt{e\mathcal{E}} + \varphi_g - \varphi) - \Delta(x_0). \quad (1)$$

Here, the term $\Delta(x_0)$ takes account of a possible deviation of the potential of the polarization forces from the Coulomb potential.[1,2]

The energy lost by an ion in the retarding field between the grid and the peak x_0' of the potential barrier at the collector (quantities referring to the collector are primed) is

$$E_2 = e(U_g - U - \sqrt{e\mathcal{E}'} + \varphi_g - \varphi') - \Delta(x_0'), \quad (2)$$

where U is the negative potential of the collector with respect to the emitter (supplied by an external source).

Above the barrier at x_0' the kinetic energy E_k of the directed motion of ions is

$$E_c = E_1 - E_2 = e(U + \varphi' - \varphi - \sqrt{e\mathcal{E}} + \sqrt{e\mathcal{E}'}) - \Delta(x_0) + \Delta(x_0'). \quad (3)$$

In an analysis of the ions on the basis of their initial energy the drift component of the energy is $E_k = 0$, so we find from (3),

$$eU_0 = e(\varphi - \varphi' + \sqrt{e\mathcal{E}} - \sqrt{e\mathcal{E}'}) + \Delta(x_0) - \Delta(x_0'). \quad (4)$$

If $\mathcal{E}$ and $\mathcal{E}'$ are relatively small (corresponding to ionization in a weak field), the quantity U_0 is equal to the contact potential difference between the emitter and the collector $U_0 = \varphi - \varphi'$. The same is true (within the difference between the correction terms Δ) when the emitter and collector form a plane capacitor in the center of which there is a plane grid.

Experiments on ionization in a strong field are usually carried out in an apparatus which is approximately a spherical capacitor, with a tip-shaped emitter. In this case $\mathscr{E}'$ and $\Delta(x_0')$ are negligibly small and Eq. (4) becomes

$$eU_0 = e(\varphi - \varphi' + \sqrt{e\mathscr{E}}) + \Delta(x_0). \tag{5}$$

When the initial ion velocities obey a Maxwell distribution, and the surfaces of the emitter and collector are homogeneous in terms of work function, the point with potential U_0 on the voltage–current curves $\log i = f(U)$ corresponds to the intersection of the two linear regions of the retardation curves (the ion-retardation region and the ion-saturation region). In the case of a constant flux of atoms (which undergo ionization) to the emitter surface, the quantity U_0 is related to the degree of ionization α, given by[1]

$$\alpha = A \exp \frac{1}{kT}\left[e(\varphi - V + \sqrt{e\mathscr{E}}) + \Delta(x_0)\right], \tag{6}$$

where T is the emitter temperature and A is the preexponential factor. The quantity α is a strong function of $\mathscr{E}$. Substituting $e\sqrt{e\mathscr{E}} + \Delta(x_0)$ from (6) into (5), we find

$$eU_0 = e(V - \varphi') + kT \ln \frac{\alpha}{A}. \tag{7}$$

If we choose the value of $\mathscr{E}$ in (6) so that $\alpha = A$, the second term in (7) vanishes at any T.

2. $\mathscr{E} > \mathscr{E}_c$. In this case $x_0 = x_{cr}$ and $e^2/4x_{cr} + \Delta(x_{cr}) = \lambda_{+0}$; the right side of this last equation is the work done against polarization forces over the entire range of these forces between x_c and $x = \infty$. Now, E_1 is not given by Eq. (1) but by

$$E_1 = e(U_c - \mathscr{E}x_{cr} + \varphi_g - \varphi) - \lambda_{+0}. \tag{8}$$

The value of E_2 for a spherical capacitor is again given by (2), where account must be taken of the conditions $e\sqrt{e\mathscr{E}'} \simeq 0$ and $\Delta(x_0') \simeq 0$. The equation analogous to (5) for eU_0 is

$$eU_0 = e(\varphi - \varphi' + \mathscr{E}x_{cr}) + \lambda_{+0}. \tag{9}$$

The degree of ionization $\mathscr{E} > \mathscr{E}_c$ is given by[1]

$$\alpha = A \exp \frac{1}{kT}\left[e(\varphi - V + \mathscr{E}x_{cr}) + \lambda_{+0}\right]. \tag{10}$$

Substituting $e\mathscr{E}x_{cr} + \lambda_{+0}$ from (10) into (9), we again find Eq. (7) for U_0.

Equation (7) differs from the equations obtained previously in the following: 1) There is no term λ'_{+0} (refs. 1,2) or $e^2/4x$ (ref. 3) in it; 2) Equation (7) takes into account the functional dependence of U_0 on α; 3) it holds for both small and large $\mathscr{E}_c$ and is not a function of the behavior of the surface potential at $x > x_{cr}$.

We assume above that the work functions φ and φ' are homogeneous over the emitter and collector surfaces. If the surfaces are inhomogeneous, the plot of the ion distribution as the function $\log i = f(U)$ will be nonlinear at small initial ion energies, and the distribution itself will be wider along the U axis. This question requires further analysis.

Equation (7) can be used in an experimental determination of the ionization potentials of particles being ionized, V, from the displacement of the retardation curves. If the retardation curves for ions of two different materials are measured under the same conditions, the relative displacement of these curves will be

$$e(U_{01} - U_{02}) = e(V_1 - V_2) + kT\left(\ln \frac{\alpha_1}{A_1} - \ln \frac{\alpha_2}{A_2}\right). \tag{11}$$

According to Eqs. (6) and (10), the value of α for ionization by a field is a very strong function of $\mathscr{E}$ in the region in which there is a change in the sign of the arguments of the exponential functions; this functional dependence is stronger, the smaller T. Accordingly, it is not difficult to experimentally choose $\mathscr{E}_1$ and $\mathscr{E}_2$ for which the second term in (11) is negligibly small. Then, knowing one of the values V, we can calculate the other from Eq. (11).

The displacement of the retardation curves for argon ions has been measured by Muller with $\mathscr{E}_1 = 1.3 \cdot 10^8$ V/cm and $\mathscr{E}_2 = 1.7 \cdot 10^8$ V/cm; it is $\Delta U_0 = U_{02} - U_{01} = 1.2$ V. A calculation from Eq. (5) yields a value only half as large: $\Delta U_0 = 0.6$ V. For inert gases ($V > 10$ V), the field desorbing the ions apparently satisfies $\mathscr{E} > \mathscr{E}_c$, so Eq. (9) should be used to evaluate this quantity.[2] The same equation can be used to evaluate x_{cr}, which we find (neglecting the functional dependence of λ_{+0} on $\mathscr{E}$) to be $x_{cr} = (\Delta U_0)/(\Delta\mathscr{E})$. According to the data given above for argon, we would have $x_{cr} = 3$ Å.

We note in conclusion that if the particles are ionized in the volume by the tunneling of an electron through the potential barrier of the particles which is "skewed" by the field (autoionization), the spatial position of the autoionization zone can be determined from the experimental retardation curves.

Investigation of the work function of a tungsten cathode after bombardment by inert-gas ions

P. N. Chistyakov, R. A. Milovanova, and V. V. Lytkin

Moscow Engineering Physics Institute

(Submitted March 26, 1973)
Zh. Tekh. Fiz., 44, 228-230 (January 1974)

It is found that the work function of a polycrystalline tungsten cathode is reduced by 0.2-0.25 eV after treatment by a high-current glow discharge in an inert gas (argon) in comparison with the standard value of φ obtained when the treatment is carried out in vacuum. A similar reduction in φ has been found earlier for a molybdenum cathode. The experimental results are explained by the variation in structure of the cathode surface and penetration of inert-gas ions of comparatively low energy (up to 250 eV) into the tungsten crystal lattice.

In earlier studies[1] the values for the work function φ obtained by the photoelectric method were compared for a polycrystalline molybdenum cathode after the following forms of treatment and purification: 1) ion bombardment in a high-current glow discharge, in an inert gas, with a pressure of units and tens of torr; 2) high-temperature heating due to the electron bombardment.

The values for φ obtained in the first case are 0.15-0.2 eV lower than in the second case, which is explained by the change in surface structure and the introduction of inert-gas ions (neon) into the molybdenum crystal lattice during the glow discharge.

Values of φ are obtained in ref. 2 for nickel, titanium, and the (001) and (110) faces of molybdenum after treatment of the cathodes by ion bombardment in a glow discharge with high current density. These values of φ are also considerably less (by 0.06-0.4 eV) than values attained in studies of other authors, where only vacuum treatment and purification of the cathode surfaces were used.

Oman and Dillon[3] have measured the work function of the (111) face of niobium using the photoelectric method. For well-annealed surfaces the work function is 4.66 eV. As a result of bombardment by argon ions, at energy 500 eV, current density 0.1 mA/cm^2, and times of 10 min and above, the work function is reduced to 4.09 eV.

Thus the effect of a reduction in the work function of a surface resulting from bombardment of inert-gas ions has been established for various metals.

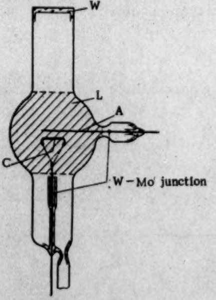

Fig. 1

The present study is a continuation of investigations carried out earlier in the laboratory of Moscow Engineering Physics Institute on the work functions of clean metal surfaces after their treatment by a high-current glow discharge in inert gases, and has been carried out for tungsten.

Tungsten, like molybdenum, is a metal for which the work function obtained in vacuum is known with good accuracy. In particular, the values of φ usually obtained for polycrystalline samples by the method of thermionic emission are in the range 4.5-4.6 eV, with the mean values being in the range 4.52-4.54 eV.

The values of φ are determined using devices of two kinds. In the first kind the principal treatment and purification of the cathodes are by a high-current glow discharge in an inert gas (argon) in a sealed-off device. The experiment with the second type of device is carried out entirely in a vacuum apparatus. The principal forms of treatment and purification of the cathode are both direct annealing in vacuum and also treatment by a high-current glow discharge in an inert gas.

Figure 1 shows the first kind of device with a plane cathode 20 mm in diameter and 0.05 mm thick. The cathode, the holders, and the principal rod, to which they are fastened, are made of tungsten. The anode is a tungsten rod 0.8 mm in diameter. To measure the spectral characteristic of the photocurrent, we direct ultraviolet light through the quartz window W onto the cathode surface.

The treatment of the device at the vacuum station consists of heating the entire device up to 400°C with a vacuum better than 10^{-5} torr, then annealing the cathode with a high-frequency current up to 1500-1700°C, first at a vacuum of order 10^{-6} torr, and after a 4-6 h annealing, the vacuum at the maximum temperature was $4-9 \cdot 10^{-7}$ torr. Next, the devices are filled with argon at pressure 4-7 torr, and the cathodes are treated with a high-current glow discharge with mean current 100-150 mA ($j = 15-25$ mA/cm^2) for 2-3 h. The argon in the system varies by a factor of 2-3 as required. During this treatment the tungsten is intensely sputtered and is deposited on the walls of the bulb of the device (layer L, Fig. 1). The normal cathode drop U_d falls in proportion to the purification of the cathode by ion bombardment in a glow discharge from 170-180 to 112-115 V. Next, the devices are sealed off from the vacuum station at an argon pressure of 12 torr.

The treatment of the cathodes by a glow discharge with mean current density 40-50 mA/cm^2 is continued in the sealed-off devices until stable and reproducible values of U_d are established; at an argon pressure of 12 torr this is 113 ± 1 V for 12 identical devices.

In addition to control of the purity of the cathode surface and gas based on the magnitude of U_d, which allows us to determine the presence of adsorbed atoms of noninert gases on the cathode surface, there is also control of the cathode surface based on post-discharge (exoelectron) emission.[4] This method allows us to determine the presence on the metal surfaces of thin films or local inclusions of dielectrics and semiconductors. Measurements show that the currents do not exceed 10^{-19} A and the decreases in time that are characteristic for post-discharge emission are not observed. Thus, there is no post-discharge emission, and the measured background current, fixed in time, can be attributed to cosmic radiation and terrestrial radioactive sources. This current has repeatedly been measured in our laboratory.

After the treatment the tungsten-cathode surface can be assumed to be atomically pure based both on the agreement among the quantities U_d for all 12 devices and on the absence of post-discharge emission.

Next, the spectral characteristics of the tungsten-cathode photocurrents are measured. A DMR-4 monochromator and a DVS-25 hydrogen lamp are used. The photocurrent in the gas medium is measured, just as in the entire series of studies beginning with ref. 1, by a statistical method of pulsed breakdown based on the mean statistical delays of the gas breakdown.

Processing the spectral characteristics according to the Fowler–Dubridge method gives an average value of the work function for 12 devices for a polycrystalline tungsten surface after ion bombardment in a high-current glow discharge in argon of 4.42 ± 0.02 eV. This value of φ is obtained for cathodes made from two samples of tungsten ribbon with impurity content no greater than 0.03%.

In the second type of device the cathode is made in the form of a tungsten strip 3 mm wide, with the length of the plane working part equal to 10 mm and the thickness 0.05 mm; direct heating by a current up to high temperatures and treatment by a high-current glow discharge in an inert gas are both allowed. The device is heated with pumping at the vacuum station up to 400°C with a system residual pressure no higher than 10^{-5} torr; then, for 15 h the cathode is annealed by a current up to a temperature 2500°C with a vacuum of order[1)] 10^{-7} torr. The device is then filled with spectroscopically pure argon and it is further purified using a titanium and molybdenum purifier. The value of φ measured after high-temperature heating of the cathode is 4.62 eV; then the argon is pumped, the cathode is again annealed up to a temperature of 2000°C for a vacuum of $2 \cdot 10^{-7}$ torr (in the same experimental device in which the Ti and Mo getters were evaporated, the vacuum was considerably greater), after which argon is admitted and the value $\varphi = 4.6$ eV is measured. This result, attained without treating the tungsten cathode with a high-current glow discharge, has been repeated several times.

Treatment of the cathode by a glow discharge in argon at a pressure of 12 torr with a current density of 18 mA/cm^2 for 2 h does not noticeably change φ; however, increasing the current density to 24 mA/cm^2 ($I = 150$ mA) and treatment of the cathode for 1 h reduces φ to 4.4 eV, and for a current density $j = 32$ mA/cm^2 ($I = 200$ mA) after 5 min of treatment, φ is decreased to 4.35 eV.

The reduction in tungsten-cathode work function that is found can be explained by the change in structure of its surface and introduction of argon ion into the tungsten crystal lattice. The latter effect is usually investigated at higher ion energies; for example, Collingon and Leck[5] noted that with bombardment of tungsten by 1-keV argon ions, the mean depth of ion penetration into the metal is 5 Å. In our experiment the cathode potential drop in the glow discharge is 180-250 V for a peak value of the current density of 70-100 mA/cm^2. In this case for a cathode temperature of about 1300°C the gas near the cathode is strongly evacuated and a certain fraction of the ions are incident on the cathode with an energy close to the total energy: 180-250 eV. As is shown by the results of this experiment, a fraction of the argon ions are introduced into the tungsten crystal lattice even at the energies being considered here.

[1)] The post-discharge emission is practically absent for all stages of the latter cathode treatment.

Switching characteristics of a discharge in water

V. M. Kuleshov, S. L. Nedoseev, V. P. Smirnov, and A. M. Spektor

(Submitted March 5, 1973)
Zh. Tekh. Fiz., 44, 230-232 (January 1974)

The switching characteristics of discharge gaps are studied in water as a function of the characteristic impedance of the shaping line ρ_s over the range 2.5-30 Ω. A line with an electrical length of 50 nsec is charged to $\nless$ 120 kV. Most of the experiments are carried out at fields up to 10^6 V/cm. The minimum rise time, $\tau_r \simeq$ 7 nsec, and the maximum rate of current increase, $I/\tau_r \simeq 10^{12}$ A/sec, are detected with ρ = 13 Ω. Up to 50% of the energy stored in the line is absorbed in the switch during a pulse. The operation remains qualitatively the same with a voltage of 400 kV on a line with ρ = 15 Ω.

The very good insulating properties of pure distilled water, which have been demonstrated on several occasions,[1,2] have been exploited in the design of high-power miniature shaping lines. Switches in which the breakdown occurs in water would be obvious candidates for use as switches with water lines. The possibility of using such switches was first raised in ref. 3. The present lack of a theory describing breakdown in water with high input-power levels complicates the practical use of water switches. Little experimental information has been reported. Alkhimov et al.[4] report the existence of a gaseous sheath around the streamer propagating from the anode toward the cathode. We can evidently expect similarities between the characteristics of water and gas switches at high gas pressures. It is difficult to obtain fast current rises, with $dI/(dt) \sim 10^{13}$ A/sec, with single-channel gas switches, so multichannel switches must be used for switching low-resistance shaping lines with water insulation. We report here a study of the pulse shape as a function of the characteristic impedance of the line being switched, carried out in order to choose the appropriate number of channels.

We have studied the characteristics of self-breakdown switches in water using shaping lines with an electrical length of τ_e = 50 nsec and characteristic impedances from 2.5 to 30 Ω. A line consisting of two strips 700 × 70 × 2 mm in size is placed in a distilled-water bath (the resistivity of the water is 200-400 kΩ · cm). The line is charged to 70-120 kV in $T \leq 0.5$ μsec. The maximum charging current at the time at which the line switch operates is below 1 kA. The radius of the hemispherical electrodes of the switch is 0.8 cm and the gap between the electrodes is varied from 1 to 1.5 mm. The charging voltage and pulse shape are monitored by a resistive divider with a resolving time of 2-3 nsec located at the open end of the line. The resistance of the divider is much higher than the characteristic impedance of the line. Most of the measurements are carried out with ρ = 2.5, 13, and 30 Ω.

The breakdown occurs at a field $\sim 10^6$ V/cm. The breakdown can be arranged to occur at the peak of the charging voltage or after it by adjusting the gap. Accordingly, the overvoltage on the switch can be adjusted. Figure 1 shows typical oscillograms of the voltage pulses. From these U(t) curves we can distinguish two stages in the development of the breakdown. In the first stage, the voltage increases rapidly to 0.5-0.8 of the peak pulse amplitude. In the second stage the voltage increases slowly, nearly to the peak value. From the circumstance that the current increase in the first stage is governed by both the inductance of the breakdown channel, L, and its resistance, R, we find $L < 10^{-8}$ H. Assuming that there is only a single breakdown channel and that its radius is a weak function of the time,[5] we can assume $dL/dt \nless 0$. Then, from the oscillograms in Fig. 1 we can easily determine R(t), the energy dissipated in the switch Q, and the efficiency of the switch switching a single shaping line with a stored energy W:

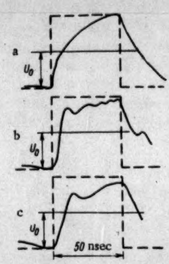

Fig. 1. Shape of the voltage pulse at the end of the open line. ρ, Ω: a) 2.5; b) 13; c) 30. Here U_0 is the charging voltage.

$$\eta_1 = \frac{W - Q}{W}.$$

We note that the value of Q/W for a double shaping line is half as large if $R(t)/\rho \ll 1$ at $t = \tau_e$. The values of τ_r, η, and I/τ_r obtained from Fig. 1 are shown in Table 1. Figure 2 shows the function R(t) for the same conditions.

The overvoltage strongly influences the pulse shape, as is evident from Fig. 3. In the "undervoltage" regime (Fig. 3b), the channel resistance oscillates rapidly, and at times the current in the channel vanishes; it reappears after a second breakdown. This behavior implies that the

TABLE 1

ρ_{ie}, Ω	U_{cha}, kV	τ_0, nsec	η_1, %	I/τ_0, A/sec
2.5	70	33	50	$5 \cdot 10^{11}$
13	100	7	50	10^{12}
30	100	12	50	$1.2 \cdot 10^{11}$
DFL, $\rho = 15$ Ω	400	22	$\eta_2 = 75\%$	$1.2 \cdot 10^{12}$

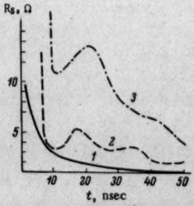

Fig. 2. Resistance of the breakdown channel of the switch as a function of the time. ρ, Ω: 1) 2.5; 2) 13; 3) 30.

pulse shape is a strong function of the electric field. In several experiments we have connected an additional line with an electrical length $\tau = 0.1\tau_e$ and with $\rho = 0.1\rho_e$ in parallel with the switch to improve the rising edge and shape of the pulse. Presumably the rising edge would improve with an increase in the energy fed to the channel in the first stage of the operation. However, this improvement turns out to be negligible, as can be seen by comparing Figs. 3b and 3c. This type of operation is unsuitable because the energy stored in the auxiliary line is approximately equal to that stored in the main line.

The scatter in the breakdown times of the switch, $\Delta\tau$, is a function of the overvoltage. If the breakdown occurs at the voltage equal to the peak of the charging voltage, $\Delta\tau$ is usually of the order of 50 nsec. Reducing this spread is an important consideration for multichannel switches in water, so we have carried out experiments with trigatron ignition in an attempt to reduce $\Delta\tau$. In these experiments the ignition pulse has a rise time of 1-2 nsec, a length of 40 nsec, and a power of up to $5 \cdot 10^7$ W. As expected, the rise time and shape of the pulse are essentially unaffected, but $\Delta\tau$ is approximately halved.

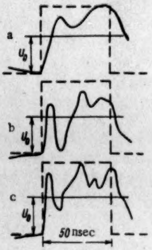

Fig. 3. Shape of the voltage pulses in a 30 Ω line. a) Breakdown with increasing voltage on the switch; b) breakdown with decreasing voltage on the switch; c) breakdown of a switch connected to a correcting line.

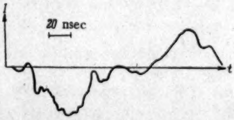

Fig. 4. Shape of the current pulse from the short-circuited double shaping line. $\rho = 15\ \Omega$, $U_0 = 400$ kV.

The characteristics of the water switch with spherical electrodes are qualitatively the same when voltage pulses at amplitudes up to 400 kV are switched. Figure 4 shows an oscillogram of the current in a short-circuited strip-type double shaping line of the Neptun accelerator with $\tau = 40$ nsec and $\rho = 15\ \Omega$ at U = 400 kV. Under these conditions we find $I/\tau_r \simeq 1.2 \cdot 10^{12}$ A/sec and $\eta_2 \simeq 75\%$, in satisfactory agreement with the data in the accompanying table for $\rho = 13\ \Omega$. The value of $\tau_r \simeq 20$ nsec can be reduced to ~ 10 nsec by increasing the overvoltage. However, this type of operation is energetically unfavorable. Since the transmitted power per unit length of the channel is $E(U/\rho)$ (where E is the electric field in the gap), we can expect to reduce the relative loss in the switching of high-power lines.

When Rogowski electrodes 70 mm in diameter are used in the switch, the discharge develops from a single point on the anode along several channels, according to the erosion tracks on the electrodes.

We note in conclusion that in our experiments on the switching of a line with $\emptyset = 70\ \Omega$ the use of multichannel water switches improves the rising edge of the pulse.

The authors thank E. K. Zavoiskii and K. I. Tarakanov for their support of this work and G. P. Maksimov for assistance in constructing the experimental apparatus.

Reversibility of chalcogenide materials in holography

S. B. Gurevich, N. N. Il'yashenko, B. T. Kolomiets, V. M. Lyubin, and M. V. Sukharev

A. F. Ioffe Physicotechnical Institute,
Academy of Sciences of the USSR, Leningrad

(Submitted June 1, 1973)
Zh. Tekh. Fiz., 44, 232-234 (January 1974)

The reversibility of glassy chalcogenide semiconducting films is studied on the basis of the relative transmission and the diffraction efficiency. The amplitude contrast is unaffected by cyclic heat treatment, which erases the recorded information, while the diffraction efficiency falls off rapidly after the first cycle. The extent of this decrease is largely a function of the film composition. It is concluded that these films, made from the appropriate materials, can be used as reversible media in holography.

An important property of glassy chalcogenide semiconductors (GCS) as media for holography is their reversibility, i.e., information can be recorded, read out, and erased repeatedly.[1-5] The conclusion that these materials are reversible is reached through a study of the change in the relative transmission of a laser beam by films of these materials before and after erasure.[1-5] Of importance for holography is not only the amplitude recording, which results from a change in transmission, but also the phase recording, which results from a change in the path difference for light rays; in the case of the GCS, there is a change in the refractive index of the material. The basic parameter of this amplitude–phase recording is chosen to be the diffraction efficiency of the holograms stored in GCS films.

We report here a joint study of the reversibility of GCS films on the basis of their relative transmission and diffraction efficiency. We use GCS films of the As–Se and As–Se–I systems obtained by deposition in vacuum on silicate glass substrates. The experiments involve a repeated recording and erasure of spots, produced by irradiating the material with an unmodulated laser beam, and they involve recording and erasing holograms (two-beam diffraction gratings). The relative transmission τ/τ_0 and the diffraction efficiency η are recorded as functions of the exposure time t. The recording and readout are achieved with an LG-36 He–Ne laser (λ = 6328 Å). In erasure the sample is placed in a thermostat and held for 10 min at a temperature from 150 to 190°C, depending on the composition of the material. After the recorded diffraction grating is erased, the residual diffraction efficiency is measured, and a new diffraction grating is recorded in the same place. In addition, analogous spots and holograms are periodically recorded in previously unexposed regions.

The experiments show that the behavior of the blackening curve as a function of the time is not affected, within the experimental error (± 10%), after erasure–recording cycles, but the diffraction efficiency falls off rapidly after the first erasure, remaining approximately constant thereafter.

Figure 1 shows illustrative plots of the relative transmission τ/τ_0 (curve 1) and the relative diffraction efficiency η/η_0 (curve 2) against the number of erasure–recording cycles N for GCS films of the As–Se–I system. The change in the relative transmission is measured after each erasure cycle, after a 10-min irradiation of the film with an unmodulated laser beam at an intensity of about 3 mW/mm^2. Here, relative diffraction efficiency means the ratio of the maximum achievable diffraction efficiency after the N-th erasure–recording cycle, η, to the maximum achievable efficiency η_0 before the first heat treatment (before the first erasure).

Since the maximum diffraction efficiency falls off severalfold after the first erasure, while the amplitude contrast is unchanged, we can suggest that it is the phase component of the recorded holograms which undergoes the greatest change after the first heat treatment; the amplitude component remains unchanged.

This behavior should apparently be interpreted on the basis of a change in the polymer structure of the GCS films caused by laser radiation, observed in ref. 4. The initial structure of fresh GCS films is evidently unstable and quite different from that of films which have been subjected to heat treatment. The change in the structure of the material during the heat treatment leads to changes in the refractive index of the films, but causes essentially no change in the absorption properties.

Another important observation is that the extent to which the diffraction efficiency is changed by the first erasure is a function of the film composition. Figure 2 shows the relative diffraction efficiency η/η_0 as a function of the number of erasure–recording cycles N for As$_2$Se$_3$ films (curve 1) as well as for films of the As–Se and As–Se–I

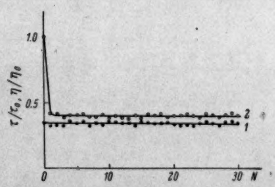

Fig. 1. Relative transmission τ/τ_0 (curve 1) and relative diffraction efficiency η/η_0 (curve 2) as functions of the number of erasure–recording cycles N for GCS films of the As–Se–I system.

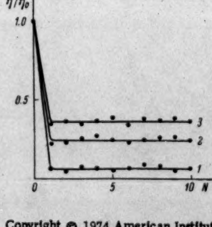

Fig. 2. Relative diffraction efficiency η/η_0 as a function of the number of erasure–recording cycles N for As$_2$Se$_3$ films (curve 1) and for films of the As–Se system (curve 2) and the As–Se–I system (curve 3).

systems (curves 2 and 3, respectively). The decrease in the diffraction efficiency is most pronounced (to 0.06) for the As_2Se_3 films and least pronounced (to 0.36) for the films of the As–Se–I system.

In none of the GCS films which we have studied do we observe a significant difference between regions of the films which had been exposed repeatedly and which had not been exposed at all.

Measurements carried out after the erasure of the holograms show that the residual diffraction efficiency is at least two orders of magnitude lower than that obtained as a result of the subsequent recording.

From these results we can draw the following conclusions:

1. The first heat-treatment cycle, which erases the information, changes the polymer structure of the GCS films in such a manner that the absorption properties are completely restored, while the refractive index is not completely restored. Subsequent erasure cycles do not change the structure of the material, so these properties remain constant after succeeding heat-treatment cycles.

2. The reversible properties of the GCS films are strongly dependent on the film composition; with an appropriate choice of material, a very small change in the diffraction efficiency after the first erasure can be achieved.

3. Since the values of the diffraction efficiency of holograms recorded on the GCS films remain approximately constant during successive erasure–recording cycles, we can think of the first heat-treatment cycle as one in which the GCS material is "formed." Obviously, GCS films can be used as reversible media for recording holograms.

Magnetoacoustic transducer based on the domain structure of a ferromagnetic material

G. L. Gurevich and G. A. Vul'gal'ter

(Submitted February 28, 1973; resubmitted June 28, 1973)
Zh. Tekh. Fiz., 44, 234-236 (January 1974)

The generation of an acoustic wave which propagates in the plane of a ferrite film divided into band domains is considered. The requirements needed for high efficiency in such a magnetoacoustic transducer are given.

To achieve efficient conversion of electromagnetic energy into acoustic energy it is necessary that the source of sound be modulated in space with a scale of the order of the wavelength of the acoustic wave. This modulation can be carried out artificially, but one can also use the inherent modulation of the properties of the solid. It is of particular interest to use the domain structure of a ferromagnetic material for this purpose.

A transducer which uses the domain structure of a film of permalloy and which excites a volume wave perpendicular to the plane of the film is considered in ref. 1. The efficiency of this transducer is extremely small.

In this paper we consider efficient generation of phonons when a wave is excited which propagates in the plane of a ferrite film which is divided into domains; the requirements on the film parameters are given. Acoustic oscillations in a thin film are easily transformed into surface acoustic waves. Thus, we consider a ferrite film of thickness L with 180-degree band domains, the walls of which are parallel to the yz plane (the z axis is in the direction of the normal to the film), deposited on a metal substrate. The dimensions of the film in the x and y directions are L_x and L_y. A metal film is deposited on top of the ferrite film, joined at $y = L_y$ with the metal substrate, so that a current-carrying loop is formed; this produces a magnetic field parallel to the x axis in the ferrite film.

We assume that the ratio of the size of a domain D to the thickness of the domain wall δ is much greater than unity, while $L \ll L_x, L_y$.

We also assume that the axis of easy magnetization is perpendicular to the plane of the film, and that the equilibrium magnetic moments $\mathbf{M}_0$ in neighboring domains are respectively parallel or antiparallel to the z axis. We assume the end of the wall x = 0 to be free. The other end of the film $x = L_x$ is loaded with a matched load, for example, it can be in contact with a medium with acoustic impedance equal to the acoustic impedance of the film.1)

A current $Je^{i\omega t}$ passes through the current-carrying loop. Since $L_x, L_y \gg L$, this current produces a uniform magnetic field $h_x e^{i\omega t} = 4\pi J/(cL_x)e^{i\omega t}$ in the ferrite film.

The high-frequency field will excite magnetization oscillations which, by virtue of magnetostriction, give rise to acoustic waves which propagate along the x axis. Since the external field is essentially uniform in the film, and the wavelength of the acoustic oscillation is of the order of $D \gg \delta$, we can neglect exchange interaction and consider the domain wall as a geometric boundary.[2] We assume that the material is isotropic in its elastic properties and neglect the acoustic attenuation. Assuming that all the quantities depend only on the x coordinate, it is easy to obtain linearized equations for the deviation of the magnetization from the equilibrium value $\mathbf{m} = \mathbf{M} - \mathbf{M}_0$, and the elastic displacement vector **u** (see ref. 3). Then, the only nonvanishing component which is excited is u_z, which satisfies the equation

$$\rho \frac{\partial^2 u_z}{\partial t^2} - c_{44} \frac{\partial^2 u_z}{\partial x^2} = \frac{B_2}{M_0^2} \frac{\partial}{\partial x} (m_x M_0(x)), \tag{1}$$

where B_2 is the magnetostriction constant, c_{44} is the elastic constant, ρ is the ferrite density, and $M_0(x) = \pm M_0$ depending on whether the magnetic moment of the domain is parallel or antiparallel to the z axis.

Neglecting the reverse action of the acoustic waves on the magnetization oscillations, m_x is found from the Landau–Lifshitz equation and has the form[4]

$$m_x = \chi_{xx} h_x = \frac{1}{\beta} \frac{\omega_0^2 + i\omega\Delta\omega}{\omega_0^2 - \omega^2 + 2i\omega\Delta\omega} h_x. \tag{2}$$

Here β is the anisotropy constant, $\omega_0 = \gamma\beta M_0$ is the ferromagnetic resonance frequency (γ is the gyromagnetic ratio), and Δω is the half-width of the ferromagnetic resonance line.

Since $M_0(x)$ oscillates with period 2D, u_z will be excited efficiently if the condition $\omega = nv(\pi/8)$ is satisfied, where n = 1, 2, 3..., and $v = \sqrt{c_{44}/\rho}$ is the velocity of sound in the ferromagnetic material.

Consider the excitation of the first harmonic $u_z(x > L_x, t) = A \exp[i\omega t - i(\omega/v_1)x]$, where v_1 is the velocity of sound in the medium in contact with the film.

The solution of Eq. (1) with the boundary conditions $[(\partial u_z/\partial x)(0, t) = 0$, continuity of $u_z(x, t)$ and $c_{44}(\partial u_z/\partial x) \cdot (x, t)$ for $x = L_x]$ yields A. We find that the acoustic flux power for $x > L_x$ is $W_a = (1/2)R_2 J^2$, and

$$R_a = \frac{64}{c^2} c_{44} \frac{\omega^2}{v} \left(\frac{B_2}{M_0 c_{44}}\right)^2 L L_y |\chi_{xx}|^2. \tag{3}$$

The Joule power loss in the ferrite can be represented in the form

$$W = -\int \overline{\left(\mathbf{m}, \frac{\partial \mathbf{h}}{\partial t}\right)} dV - \frac{1}{2} R J^2$$

(the wavy bar denotes averaging over the period of the oscillations), where

$$R = -\frac{16}{c^2} \pi^2 \omega \frac{L L_y}{L_x} \operatorname{Im} \chi_{xx}, \tag{4}$$

In addition, the portion of the power W_p dissipated in the current-conducting plates and the reactive element, which it is necessary to connect to the above system to compensate its inherent reactance, is

$$W_p = \frac{\omega |\mathscr{L}|}{2c^2 Q} J^2,$$

where

$$\mathscr{L} = 4\pi \frac{LL_y}{L_x}(1 + 4\pi Re\chi_{xx})$$

is the inductance of the system, and Q is the Q factor of the reactive elements.

Note that L and D are connected by the relation[5] $D = (\alpha\beta)^{1/4}(L)^{1/2}$ (α is the exchange interaction constant).

The condition for the transducer to be efficient is $W_a \gg W, W_p$, whence it follows that

$$\frac{W_a}{W} = \frac{4}{\pi} Nc_{44}\left(\frac{B_2}{M_0c_{44}}\right)^2 \frac{|\chi_{xx}|^2}{-\mathrm{Im}\,\chi_{xx}} \gg 1, \tag{5}$$

$$\frac{W_a}{W_p} = 16Nc_{44}\left(\frac{B_2}{M_0c_{44}}\right)^2 \frac{|\chi_{xx}|^2}{|1 + 4\pi\,\mathrm{Re}\,\chi_{xx}|} \gg \frac{1}{Q}, \tag{6}$$

where $N = L_x/D$ is the number of domains in the length of the transducer.

In very thin films a state of uniform magnetization is energetically more suitable, since this leads to the existence of a domain of minimum dimensions in a film of given material. In this case we must distinguish two cases:[6] If $\beta < 4\pi$, the minimum dimensions of the domain $D_{\min} \simeq \pi\sqrt{3\alpha/\beta}$, and if $\beta > 4\pi$, then $D_{\min} \simeq \sqrt{\alpha\beta/4}$. It is clear that a necessary condition for constructing a transducer which operates at a given frequency ω is the condition $D = v(\pi/\omega) > D_{\min}$, which gives

$$\left.\begin{aligned} &\sqrt{\frac{\alpha}{\beta}} < \frac{v}{\omega\sqrt{3}}, \quad \beta < 4\pi, \\ &\sqrt{\alpha\beta} < 4\pi\frac{v}{\omega}, \quad \beta > 4\pi. \end{aligned}\right\} \tag{7}$$

For yttrium iron garnet $c_{44} = 7.64 \cdot 10^{11}$ dynes/cm^2, $v = 3.84 \cdot 10^5$ cm/sec, $B_2 = 6.96 \cdot 10^6$ ergs/cm^3, $M_0 = 139$ G, $\alpha = 3.73 \cdot 10^{-11}$ cm^2, $\beta = 2K_1/M_0^2 = 0.65$, $\gamma = 1.76 \cdot 10^7$ Oe^{-1} · sec^{-1}, and $\Delta\omega/\omega_0 \sim 10^{-3}$ (ref. 7), so that at a frequency of 1 GHz for N = 50 we obtain $W_a/W \simeq 5$, $W_a/W_p \simeq 0.07$.

Hence, for values of Q that can be achieved in practice (Q ~ 100) conditions (5) and (6) are satisfied. If we assume that $L_y = 10L$, then $R_a \simeq 0.12\Omega$. The input impedance with a compensating reactance connected in parallel with the transducer is $(\omega L^2)/R_a \simeq 25\Omega$. Since the working frequency in our example is far from the ferromagnetic resonance ($\omega \simeq 4\omega_0$), the bandwidth of the transducer is not determined by the narrow ferromagnetic resonance line, but by the number of domains N (the order of magnitude of the relative bandwidth is 1/N).

The above estimates indicate that a transducer based on domains should be quite efficient. To increase the operating frequency it is obviously necessary to choose a material with a magnetostriction constant B_2 greater than that of yttrium iron garnet, and a higher resonance frequency.

In conclusion we note the possibility of controlling the working frequency of the transducer. The application of a constant external field perpendicular to the surface of the film leads to a change in the period of the domain structure, and it can be easily shown that the relative change in the period is determined by the parameter $[H_0/(\beta M_0)]^2$, where H_0 is the applied field. Since the working frequency is inversely proportional to the period of the domain structure, the application of an external field leads to a change in the working frequency.

[1)] In particular, this medium can be the ferrite film itself of thickness L, on the surface of which is deposited a current-carrying metal film.

Calculation of permittivity of an inhomogeneous dielectric by a variational method

G. A. Ermakov, A. G. Fokin, and T. D. Shermergor

(Submitted May 14, 1973)
Zh. Tekh. Fiz., 44, 241-248 (February 1974)

A variational method is presented for calculating the effective permittivity of an inhomogeneous dielectric, ε^*. It is shown that this method can be used to construct an exact expression for ε^* representing an expansion in terms of multiple-point correlation functions of all orders. The lowest approximation of the method corresponds to the singular approximation of the renormalization method, based on the theory of random functions. In the second part the variational principle is used to bracket the values of ε^*. With this in mind the approximation which assumes the field is uniform within each phase (the UPF approximation) is applied and the conditions under which the UPF approximation agrees with the singular approximation are analyzed. Expressions are obtained for the effective constants in the UPF approximation when it does not agree with the singular approximation.

Among the various approximation methods used to calculate the effective permittivities of inhomogeneous dielectrics the ones which have gained the most acceptance are the variational method first proposed by Hashin and Shtrikman,[1] the renormalization method based on the theory of random functions,[2] the self-consistent method,[3] and the structure regularization approximation[4] in which the actual structure is replaced by an idealized strictly periodic structure. Each of these methods has its advantages and disadvantages. The variational method generally leads to exact upper and lower bounds for the effective permittivity ε^*_{ij}, but these are far apart. With the renormalization method an exact expression for the effective permittivity can be constructed formally but a direct calculation cannot be carried through since it requires taking account of multiple-point correlation functions of all orders. This difficulty is commonly avoided by limiting the calculation to the lower approximations of the method,[2] or to the singular approximation[5] which takes account only of the singular components of the second derivatives of the Green's function. In this approximation the renormalization method leads to upper and lower values of the effective permittivity, but the question of whether they form bounds is difficult to resolve without energy arguments. The self-consistent method is convenient because of its simplicity. Ordinarily it leads to an approximate value lying within the Hashin–Shtrikman bracket. The disadvantage of the method is that it does not take account of the interaction of the components, so that it is not suitable for describing matrix mixtures. The advantage of the structure regularization method is that it does not require the assumption of small concentrations or small differences of the permittivities of the components, but replacing a disordered structure by an idealized regular one introduces a certain error.

The availability of a large number of approximation formulas for calculating effective permittivities of various structures poses the problem of choosing the appropriate theoretical formula for describing an actual system. Because of the large variety of real structures an experimental test of various theoretical formulas involves extensive study. In this connection it is of interest to compare various methods in order to find the possibilities of their further development or to determine the limits within which a given method is not only valid a priori, but also leads to the smallest error. We analyze the variational and the renormalization methods from this point of view. It is shown first that the variational method gives a formal rigorous solution of the problem, and as in the renormalization method, the calculation of the effective permittivity in explicit form reduces to the evaluation of multiple integrals containing multiple-point correlation functions of all orders.

In the second part the approximation in which the field is uniform in each phase (the UPF approximation) is discussed and the conditions under which this approximation is equivalent to the singular approximation are analyzed.

1. FORMAL CONSTRUCTION OF THE EFFECTIVE PERMITTIVITY USING A VARIATIONAL METHOD

We consider an inhomogeneous dielectric whose permittivity tensor ε_{ij} is a random function of coordinates, and a homogeneous dielectric (comparison body) with the same size and shape with the permittivity ε^c_{ij}. This approach permits the introduction of the polarization vector $\tau_i = D_i - \varepsilon^c_{ij}E_j$, where D and E are respectively the electric displacement and the electric field in the inhomogeneous dielectric.

We denote the average values of quantities by angle brackets, the deviations of quantities from their values in the comparison body by primes, and central random values by double primes:

$$\varepsilon'_{ij} = \varepsilon_{ij} - \varepsilon^c_{ij}, \quad \tau''_i = \tau_i - \langle\tau_i\rangle. \tag{1.1}$$

We limit our discussion to ergodic fields for which statistical averaging over an ensemble agrees with volume averaging. We average over a volume whose linear dimensions are very much larger than the spatial scale of correlations, but small as compared with distances over which the regular part of the functions changes significantly. Then according to the variational principle formulated for this problem by Hashin and Shtrikman[1] the functional

$$U = \frac{1}{2}\int \left(\varepsilon^c_{ij}\langle E_i\rangle\langle E_j\rangle - \tau_i p_{ij}\tau_j + \tau''_i E''_i + 2\tau_i\langle E_i\rangle\right) d\mathbf{r}, \tag{1.2}$$

will be stationary for fields which satisfy

$$E_i = p_{ij}\tau_j, \quad p_{ij}\varepsilon'_{jk} \equiv \delta_{ik} \tag{1.3}$$

with the subsidiary and boundary conditions

$$\nabla_i\left(\varepsilon^c_{ij}E''_j + \tau''_i\right) = 0, \quad \varphi''|_S = 0, \quad \mathbf{E} = -\nabla\varphi. \tag{1.4}$$

The stationary value of the functional (1.2) is an absolute minimum when $\varepsilon^c_{ij} - \varepsilon_{ij} \geq 0$, and an absolute maximum otherwise. Here, the matrix inequality is understood in the sense of the positive semidefinite character of the quadratic form.

We determine the Green's function G of the regular operation L^c by the equation

$$L^cG = -\delta(\mathbf{r}),\quad L^c \equiv \nabla_i \varepsilon^c_{ij} \nabla_j. \tag{1.5}$$

Then using the first equation in (1.4) we obtain

$$E''_i = G_{,ij} * \tau''_j \equiv Q_{ij}\tau''_j. \tag{1.6}$$

Here, the subscripts after the comma denote differentiation with respect to the corresponding coordinates, the asterisk denotes convolution, and Q_{ij} is an integral operator whose kernel is $G_{,ij}$.

Substituting the value of $\mathbf{E}''$ determined from (1.6) into Eq. (1.2) we obtain a functional specified by the noncentral random functions τ. By varying this functional with respect to τ we find its stationary value and the functions for which it is stationary:

$$U_0 = \frac{1}{2}\int (\varepsilon^c\langle\mathbf{E}\rangle + \langle\tau\rangle)\langle\mathbf{E}\rangle\, d\mathbf{r} \equiv \frac{1}{2}\int \varepsilon^*\langle\mathbf{E}\rangle^2 d\mathbf{r}, \tag{1.7}$$

$$\tau = (p - Q)^{-1}[\langle\mathbf{E}\rangle - Q\langle\tau\rangle]. \tag{1.8}$$

From now on we use matrix notation and drop the subscripts on vectors and tensors.

Averaging Eq. (1.8) and expressing $\langle\tau\rangle$ and τ'' in terms of $\langle\mathbf{E}\rangle$ we find from Eqs. (1.6)-(1.8), after some transformations,

$$\mathbf{E} = (I - Q\varepsilon')^{-1}\langle(I - Q\varepsilon')^{-1}\rangle^{-1}\langle\mathbf{E}\rangle, \tag{1.9}$$

$$\varepsilon^* = \langle\varepsilon(I - Q\varepsilon')^{-1}\rangle\langle(I - Q\varepsilon')^{-1}\rangle^{-1}. \tag{1.10}$$

In obtaining Eqs. (1.7)-(1.10) we use the fact that the integral operator Q is symmetric, i.e., it satisfies the functional equation $(\varphi, QF) = (Q\varphi, f)$.

We express the second derivative of the Green's function as the sum of singular and regular components

$$\left.\begin{aligned} &G_{,ij} = G^s_{,ij} + G^f_{,ij},\quad \int G^s_{,ij}\varphi\, d\mathbf{r} \equiv \varphi(0)g_{ij},\quad g_{ij} \equiv \int_{V_0} G_{,ij}\, d\mathbf{r},\\ &\int G^f_{,ij}\varphi\, dr \equiv \int_{V_0} G_{,ij}[\varphi - \varphi(0)]\, d\mathbf{r} + \int_{V-V_0} G_{,ij}\varphi\, d\mathbf{r}, \end{aligned}\right\} \tag{1.11}$$

where $\varphi(\mathbf{r})$ is an arbitrary, finite, twice differentiable function, and the volume element V_0 includes the origin. Since $G_{,ij}$ is a homogeneous generalized function of degree −3 the integral g_{ij} depends only on the shape of the volume element $V_0 \subset V$, and not on its size.[6]

From the equations given above it is clear that the partition of $G_{,ij}$ and, consequently, the partition of the integral operator Q_{ij}, into singular and regular components is not unique but depends on the shape of the surface of the element V_0. The question of the choice of shape of this element is discussed in the second section of this paper.

Since $G^s_{,ij} = g_{ij}\delta(\mathbf{r})$, the integral operator Q^s_{ij} degenerates into a constant tensor g_{ij}, whereas Q^f_{ij} remains an integral operator.

We introduce the operators[7]

$$R \equiv (I - Q^f l)^{-1}\langle(I - Q^f l)^{-1}\rangle^{-1} = \lim_{n\to\infty} R_n,$$

$$R_n \equiv \sum_{k=0}^{n} (Hl)^k,$$

$$H \equiv (I - M)Q^f,\quad M\varphi \equiv \langle\varphi\rangle,$$

$$l \equiv \varepsilon'(I - g\varepsilon')^{-1} = (p - g)^{-1} \tag{1.12}$$

and use the representation that follows from the definitions (1.11) and (1.12):

$$\left.\begin{aligned} I - Q\varepsilon' &= (I - Q^f l)(I - g\varepsilon'),\\ (I - Q\varepsilon')^{-1} &= (I - g\varepsilon')^{-1}R\langle(I - Q^f l)^{-1}\rangle,\\ \langle(I - Q\varepsilon')^{-1}\rangle^{-1} &= \langle(I - Q^f l)^{-1}\rangle^{-1}\langle(I - g\varepsilon')^{-1}R\rangle^{-1}. \end{aligned}\right\} \tag{1.13}$$

Then, substituting Eq. (1.13) into (1.9) we find

$$\mathbf{E} = A\langle\mathbf{E}\rangle,\quad A \equiv (I - g\varepsilon')^{-1}R\langle(I - g\varepsilon')^{-1}R\rangle^{-1}. \tag{1.14}$$

Hence, replacing R by R_n we obtain

$$\mathbf{E} = \lim A_n\langle\mathbf{E}\rangle,\quad A_n \equiv (I - g\varepsilon')R_n\langle(I - g\varepsilon')^{-1}R_n\rangle^{-1}. \tag{1.15}$$

Limiting ourselves to the n-th approximation in powers of the random operator Hl, we find approximate values of the total field and the effective permittivity:

$$\mathbf{E}^{(n)} = A_n\langle\mathbf{E}\rangle,\quad \varepsilon^{(n)} = \langle\varepsilon A_n\rangle. \tag{1.16}$$

Equation (1.16) together with (1.12) and (1.15) for all n agrees with the solutions obtained by the renormalization method.[7] Thus the description of inhomogeneous media by variational principles is equivalent to the description by the renormalization method.

In the limiting case n → ∞ the approximate solutions (1.16) for the field $\mathbf{E}^{(n)}$ and the effective permittivity $\varepsilon^{(n)}$ go over into the exact solution (1.14). The other limiting case n = 0 gives the singular approximation of the variational method. Setting n = 0 in Eq. (1.16) and using (1.6) we find

$$\mathbf{E}^{(0)} = (I - g\varepsilon')^{-1}\langle(I - g\varepsilon')^{-1}\rangle^{-1}\langle\mathbf{E}\rangle, \tag{1.17}$$

$$\varepsilon^{(0)} = \langle\varepsilon(I - g\varepsilon')^{-1}\rangle\langle(I - g\varepsilon')^{-1}\rangle^{-1}. \tag{1.18}$$

These same equations can also be obtained by using the singular approximation of the renormalization method.

Substitution of the explicit expression for A_n into Eq. (1.16) for the effective permittivity yields a cumbersome expression. To simplify it we consider the case in which the fields $\langle\tau\rangle$ and $\langle\mathbf{E}\rangle$ are uniform. Then the operator Q_{ij} degenerates into the constant tensor

$$Q_{ij}\langle\tau_j\rangle = G_{,ij} * \langle\tau_j\rangle = g_{ij}\langle\tau_j\rangle, \tag{1.19}$$

and Eq. (1.8) is replaced by

$$\tau = (p - Q)^{-1}[\langle\mathbf{E}\rangle - g\langle\tau\rangle]. \tag{1.20}$$

We average this expression and express $\langle\tau\rangle$ and τ'' in terms of $\langle\mathbf{E}\rangle$. Then, using (1.7) we find

$$\varepsilon^* = \varepsilon^c + [g + \langle(p - Q)^{-1}\rangle^{-1}]^{-1} I. \tag{1.21}$$

We introduce the notation

$$p^* = (\varepsilon^* - \varepsilon^c)^{-1},\quad l^* = (p^* - g)^{-1}. \tag{1.22}$$

Then using the last of Eqs. (1.12) and (1.13), Eq. (1.21) can be written in the form

$$l^* = \lim_{n\to\infty} l^{(n)},\quad l^{(n)} = \langle lY^{(n)}\rangle,\quad Y^{(n)} = \sum_{k=0}^{n}(Q^f l)^k. \tag{1.23}$$

Here, $Y^{(n)}$ is a constant tensor. The equation obtained, together with (1.22), determines both the exact and the approximate values of the effective permittivity. We emphasize that in (1.23) the expansion is carried out with the regular parts of the second derivatives of the Green's function.

In the singular approximation (n = 0) we find $l^{(0)} = \langle l\rangle$ which is equivalent to (1.18).

For uniform average fields $\langle E\rangle$ and $\langle \tau\rangle$ the expression for the total field E is also simplified. Using (1.19) we find

$$\mathbf{E} = (I - g\varepsilon')^{-1} Y^{(\infty)} (I - g\varepsilon^{*\prime})\langle \mathbf{E}\rangle, \quad \varepsilon^{*\prime} \equiv \varepsilon^* - \varepsilon^0. \tag{1.24}$$

By using (1.22) this equation can be written in a somewhat different form:

$$\mathbf{E} = \lim_{n\to\infty} \mathbf{E}^{(n)}, \quad \mathbf{E}^{(n)} = plY^{(n)}(p^{(n)}l^{(n)})^{-1}\langle \mathbf{E}\rangle, \quad p^{(n)} \equiv (\varepsilon^{(n)} - \varepsilon^0)^{-1}. \tag{1.25}$$

The singular approximation (1.17) is obtained from this for n = 0.

2. THE UPF APPROXIMATION

The singular approximation involves only the local field, i.e., the total field at a given point is determined only by its average value and the random component of the permittivity. Another procedure is possible, based only on the assumption of the uniformity of the field within each phase (the UPF approximation). It will be shown later that in this approximation, first applied by Hashin and Shtrikman, the field in a given phase is generally determined not only by the average field and the random component of the permittivity in that phase, but also by the values in all other phases.

We discuss the UPF approximation for a multiphase mixture of isotropic components. We define phase averaging by using the scalar indicator function f_α which is equal to unity if the given point belongs to the phase under consideration, and zero otherwise. The average value of the indicator function and the dependence of the structure function on it are given by

$$\begin{gathered}\langle f_\alpha\rangle = v_\alpha, \quad x_{\alpha\beta}(\mathbf{r}) \equiv \langle f_\alpha(\mathbf{r}_0) f_\beta(\mathbf{r}_0 + \mathbf{r})\rangle = v_\alpha v_\beta + B_{\alpha\beta}\varphi_{\alpha\beta}(\mathbf{r}),\\ B_{\alpha\beta} = B_{\beta\alpha} = v_\alpha(\delta_{\alpha\beta} - v_\beta), \quad \varphi_{\alpha\beta}(0) = 1.\end{gathered} \tag{2.1}$$

The components of the correlation indicator function $\varphi_{\alpha\beta}$ are related by

$$\varphi_{\alpha\alpha} = \sum_\beta v_\beta \varphi_{\alpha\beta}, \tag{2.2}$$

which follows from summing the second of Eqs. (2.1) over β. Hence for a two-phase mixture $\varphi_{11} = \varphi_{22} = \varphi_{12} = \varphi$. However, for a multiphase mixture the various components can be described by different functions $\varphi_{\alpha\beta}$, reflecting different ordering of the phases. We denote the phase averaging operator by M_α. Then we find from Eq. (1.6)

$$\left.\begin{gathered}M_\alpha E''_i(\mathbf{r}) = \frac{1}{v_\alpha}\langle E''_i(\mathbf{r}) f_\alpha(\mathbf{r})\rangle = \frac{1}{v_\alpha}\int G_{,ij}(\mathbf{r}) K_{\alpha j}(\mathbf{r})\,d\mathbf{r},\\ K_{\alpha j}(\mathbf{r}) \equiv \langle f_\alpha(\mathbf{r}_0)\tau''_j(\mathbf{r}_0 + \mathbf{r})\rangle.\end{gathered}\right\} \tag{2.3}$$

We now assume that the field $\tau''_j(\mathbf{r})$ is uniform within each phase:

$$\tau''_j(\mathbf{r}) = \sum_\beta^n f_\beta(\mathbf{r})\tau''_{\beta j}. \tag{2.4}$$

Substituting (2.4) into (2.3) we find

$$K_{\alpha j}(\mathbf{r}) = \sum_\beta^n \tau''_{\beta j} x_{\alpha\beta}(\mathbf{r}), \tag{2.5}$$

which, after substitution into the first equation in (2.3), gives

$$E''_{\alpha i} \equiv M_\alpha E''_i = \sum_\beta^n C^{\alpha\beta}_{ij}\tau''_{\beta j}, \quad C^{\alpha\beta}_{ij} = \frac{1}{v_\alpha}\int G_{,ij}(\mathbf{r}) x_{\alpha\beta}(\mathbf{r})\,d\mathbf{r}. \tag{2.6}$$

It follows from Eqs. (2.6) and (1.5) that the coefficients $C^{\alpha\beta}_{ij}$ have the following properties:

$$v_\alpha C^{\alpha\beta}_{ij} = v_\beta C^{\beta\alpha}_{ij}, \quad \varepsilon^0_{ij} C^{\alpha\beta}_{ij} = -\delta_{\alpha\beta}. \tag{2.7}$$

Substituting the explicit value of $x_{\alpha\beta}$ into the second equation in (2.6) we find

$$\left.\begin{gathered}C^{\alpha\beta}_{ij} = q^{\alpha\alpha}_{ij}\delta_{\alpha\beta} + v_\beta(g_{ij}\Theta_{\alpha\beta} - q^{\alpha\beta}_{ij}),\\ q^{\alpha\beta}_{ij} = \int G_{,ij}(\mathbf{r})\varphi_{\alpha\beta}(\mathbf{r})\,d\mathbf{r},\end{gathered}\right\} \tag{2.8}$$

where the tensor g_{ij} is given by (1.11) and all the elements of the matrix $\{\Theta_{\alpha\beta}\}$ are unity.

Thus in the UPF approximation the quantity $E''_{\alpha i}$ is determined not only by the value of $\tau''_{\alpha j}$ in that phase, but also by its values in all the other phases. In the singular approximation, on the other hand, correlation relations between phases are ignored. By replacing $G_{,ij}$ by $G^s_{,ij}$ in the second of Eqs. (2.8) we obtain

$$q^{\alpha\beta s}_{ij} = g_{ij}\Theta_{\alpha\beta}, \quad C^{\alpha\beta s}_{ij} = g_{ij}\delta_{\alpha\beta}, \quad E''^s_{\alpha i} = g_{ij}\tau''_{\alpha j}. \tag{2.9}$$

On the other hand the last equation in (2.9) is obtained directly from (1.6) by multiplying it on the left by the operator M_α and replacing $G_{,ij}$ by $G^s_{,ij}$.

Since the UPF approximation brackets the value of the effective permittivity, it follows from (2.8) that the singular approximation gives a bracket only when $q^{\alpha\beta}_{ij} \equiv g_{ij}\Theta_{\alpha\beta}$. Using the singular approximation for $q^{\alpha\beta}_{ij} \neq g_{ij}\Theta_{\alpha\beta}$ would significantly distort the form of the functional (1.2) and therefore would destroy its extremum character. Thus, using the relation

$$E''_{\alpha i} = q^{\alpha\alpha}_{ij}\tau''_{\alpha j} - \sum_\beta^n v_\beta q^{\alpha\beta}_{ij}\tau''_{\beta j}, \tag{2.10}$$

which holds in the UPF approximation, the third term of the functional (1.2) determining the nonlocal relations between D_i and E_i takes the form

$$\langle \tau''_i E''_i\rangle = \sum_\alpha^n v_\alpha \tau''_{\alpha i} q^{\alpha\alpha}_{ij}\tau''_{j\alpha} - \sum_\alpha\sum_\beta v_\alpha v_\beta \tau''_{\alpha i} q^{\alpha\beta}_{ij}\tau''_{\beta j}, \tag{2.11}$$

whereas in the singular approximation (2.11) is replaced by

$$\langle \tau''_i E''^s_i\rangle = \sum_\alpha^n v_\alpha \tau''_{\alpha i} g_{ij}\tau''_{\alpha j}, \tag{2.12}$$

which shows, as already noted, that in this approximation correlation relations between phases are not taken into account.

Thus the UPF approximation always gives bounds, while the singular approximation does so only when $q^{\alpha\beta}_{ij} = g_{ij}\Theta_{\alpha\beta}$. We show that the sufficient condition for the agreement of the two approximations is

$$\varphi_{\alpha\beta}(\mathbf{r}) = \Phi_{\alpha\beta}(\rho), \quad \rho^2 \equiv a_{ik}x_i x_k, \tag{2.13}$$

where a_{ik} is a certain symmetric constant tensor and $\Phi_{\alpha\beta}(\rho)$ is any function compatible with the usual conditions imposed on the coordinate dependence of the correlation functions.[8] To do this we perform the integration in the second of Eqs. (2.8). We extend the integration over the individual layers ($\rho_{n-1}, \rho_n = \rho_{n-1} + \Delta\rho$) with a common center of similitude. Then the function $\varphi_{\alpha\beta}(\mathbf{r})$ is changed only in the direction normal to the surface of the layer. Therefore, assuming that $\Delta\rho$ is sufficiently small and applying the theorem of the mean we obtain

$$q_{ij}^{\alpha\beta} = g_{ij}^{\alpha\beta}(0)\,\varphi_{\alpha\beta}(0) + \sum_{n=1}^{\infty} \varphi_{\alpha\beta}(n)\,[g_{ij}(n) - g_{ij}(n-1)], \tag{2.14}$$

where $\varphi_{\alpha\beta}(n)$ is the value of the function $\varphi_{\alpha\beta}(\mathbf{r})$ in the n-th layer, $g_{ij}(n)$ is the function defined by Eq. (1.11), calculated by integrating over the outer surface of the corresponding layer. Taking account of the fact that the tensor g_{ij} depends only on the shape of the volume of integration V_0 and not on its size we find that $g_{ij}(n) = g_{ij}(n-1)$ for any n, and hence $q_{ij}^{\alpha\beta} = g_{ij}(0)\Theta_{\alpha\beta} \equiv g_{ij}\Theta_{\alpha\beta}$. This shows the agreement of the two approximations when $\varphi_{\alpha\beta}(\mathbf{r})$ satisfies (2.13). It also follows that if $\varphi_{\alpha\beta}(\mathbf{r})$ is described by (2.13) the shape of the element of volume of integration in Eq. (1.11) is given by the shape of the characteristic surface $a_{ik}x_i x_k$ = const.

As an example of a relation of the type (2.13) we cite correlation functions of the form

$$\ln \varphi_{\alpha\beta} = -b_{\alpha\beta}\rho^m, \quad m = 1,\ 2, \tag{2.15}$$

used to describe textured multiphase systems assumed to have identical phase interactions. Here the factors $b_{\alpha\beta}$ take account of the difference in scales of correlation between different phases.

The approximation which assumes a uniform field within each phase agrees with the singular approximation, i.e., $q_{ij}^{\alpha\beta} = q_{ij}\Theta^{\alpha\beta}$ if $\varphi_{\alpha\beta} = \varphi\Theta_{\alpha\beta}$ and therefore $q_{ij}^{\alpha\beta} = q_{ij}\Theta_{\alpha\beta}$ for the structures under consideration. This follows from (1.5), (2.7), and (2.8). Structures for which $\varphi_{\alpha\beta} = \varphi\Theta_{\alpha\beta}$ include two-phase composite materials with isotropic components, single-phase and two-phase nontextured polycrystalline aggregates, and certain types of textured polycrystalline aggregates.

If the structure under investigation is such that the correlation function $\varphi_{\alpha\beta}$ is different for different phases, the calculation of the effective permittivity is complicated. We present a calculation for this case. Substituting Eq. (2.10) into the functional (1.2) and using (2.2) and (2.8) we find that it has an extremum for fields satisfying

$$\tau_{\alpha i} = \sum_{\beta} (X^{-1})_{ij}^{\alpha\beta}\, v_\beta \langle E_j \rangle, \tag{2.16}$$

$$X_{ij}^{\alpha\beta} \equiv v_\alpha [(p_{ij}^{\alpha} - q_{ij}^{\alpha\alpha})\,\delta_{\alpha\beta} + v_\beta q_{ij}^{\alpha\beta}].$$

Here, the quantities p_{ij} are given by (1.3). Averaging (2.16) and substituting it into (1.7) we find

$$\varepsilon_{ij}^{*} = \varepsilon_{ij}^{c} + \sum_{\alpha}\sum_{\beta} v_\alpha v_\beta (X^{-1})_{ij}^{\alpha\beta}. \tag{2.17}$$

It is easy to see that for $q_{ij}^{\alpha\beta} = q_{ij}\Theta_{\alpha\beta}$, i.e., when the UPF approximation degenerates into the singular approximation, Eq. (1.18) for the effective permittivity follows from Eqs. (2.16) and (2.18).

The generalization of the variational method we have proposed enables us, in principle, to find the exact value for ε_{ij}^{*}, since the necessary information on the structure of the inhomogeneous material is contained in the multiple-point moment functions of the permittivity. However, the same difficulties arise as in the renormalization method, namely the insufficiency of the information on the relations of the multiple-point correlation functions to the structure function and the mathematical difficulties involved in evaluating integrals of high multiplicity. At the present time these difficulties are overcome in the renormalization method by using the singular approximation, and in the variational method by the UPF approximation. We emphasize that in the formulation of the variational method Hashin and Shtrikman considered only those media for which the UPF and the singular approximations agree.

From what was shown in the first part of this paper on the equivalence of the two methods it follows that both can be used to calculate complex structures, but in this case either the singular approximation or the UPF approximation must be used in its most general form.

The width of the bracket for ε_{ij}^{*} is critically dependent on a proper choice of the permittivity of the comparison body. Thus choosing successively $\varepsilon^c = \varepsilon_1$ and $\varepsilon^c = \varepsilon_2$ for a two-phase composite consisting of isotropic phases we obtain the Hashin–Shtrikman bracket. Other combinations of ε_α and v_α can also be chosen as ε^c. The problem of the optimum choice of ε_{ij}^{c} for various inhomogeneous dielectrics is discussed in the following paper.

Calculation of bounds for the effective permittivity of an inhomogeneous dielectric

G. A. Ermakov, A. G. Fokin, and T. D. Shermergor

(Submitted June 7, 1973)
Zh. Tekh. Fiz., 44, 249-256 (February 1974)

Using a variational method the bounds for effective permittivities are calculated by optimizing the properties of a comparison body. It is shown that for a number of structures this method brackets the permittivity values more closely than the Hashin–Shtrikman method. The calculation is performed for a nontextured N-component mixture of isotropic phases, a nontextured N-phase polycrystalline aggregate, and a filamentary composite. Working formulas are obtained for the case of a very inhomogeneous phase consisting of either a multilayer cylinder or a multilayer sphere.

A comparison of the variational and the renormalization methods for calculating the permittivity of microscopically inhomogeneous dielectrics shows that for a number of structures the approximation which assumes the field is uniform within a given phase (the UPF approximation), applied for the first time in the variational method, and the singular approximation developed initially in the renormalization method lead to the same results.[1] Thus the bounds for the effective permittivity ε^* of such structures can be calculated from singular-approximation equations expressing ε^* in terms of the permittivity ε^c of a comparison body, and ε^c can be determined by the variational method.

We discuss three very simple cases: a composite of isotropic phases, a multiphase polycrystalline aggregate, and monodirectional anisotropic filaments in an isotropic matrix. The corresponding values of the effective permittivity are

$$\varepsilon^* = \left[\sum_{\alpha=1}^{N} v_\alpha (\varepsilon_\alpha + 2\varepsilon^c)^{-1}\right]^{-1} - 2\varepsilon^c \tag{1}$$

for a nontextured N-component mixture of isotropic phases,

$$\varepsilon^* = 3\left(\sum_{\alpha=1}^{N} v_\alpha \Delta^\alpha_{ii}\right)^{-1} - 2\varepsilon^c, \quad \Delta^\alpha_{ik}(\varepsilon^\alpha_{kj} + 2\varepsilon^c_{kj}) \equiv \delta_{ij} \tag{2}$$

for a nontextured N-phase polycrystalline aggregate, and

$$\begin{aligned} \varepsilon^*_{11} = \varepsilon^*_{22} = 2\{v_f[(\varepsilon^f_{11} + \varepsilon^c_{11})^{-1} + (\varepsilon^f_{22} + \varepsilon^c_{11})^{-1}] \\ + 2v_m(\varepsilon_m + \varepsilon^c_{11})^{-1}\}^{-1} - \varepsilon^c_{11}, \\ \varepsilon^*_{33} = v_f\varepsilon^f_{33} + v_m\varepsilon_m \end{aligned} \tag{3}$$

for a composite consisting of filaments of orthorhombic symmetry in an isotropic matrix, with both the filaments and one of the axes of second order oriented along the x_3 axis. Here Greek letters denote the number of the phase, v_α is the volume fraction of phase α, ε^s_{ij} is the effective permittivity in the singular approximation, and the indices f, m, and c denote quantities referring to a filament, the matrix, and the comparison body, respectively.

Equations (1)-(3) determine the effective values of the permittivity of multiphase structures with an irregular spatial distribution of phases. It is assumed that each of the phases is homogeneous. In addition, many composite materials have very inhomogeneous phases. Typical examples are fiberglass-reinforced plastics in which reinforcement is provided by hollow glass fibers or coated fibers. But even in polycrystalline aggregates and composites with inert fillers the properties of a phase within a grain can vary due to the increase of defects in regions near boundaries and the resulting nonuniform distribution of impurity atoms. This inhomogeneity should be taken into account if the thickness of the boundary layer separating the grains of an inhomogeneous material is comparable with the average size of a grain of the inhomogeneity.

The approximate value of the effective permittivity of such complex systems can be calculated as before by using Eqs. (1)-(3), but now the permittivity of a given phase must take account of the inhomogeneity. It should be emphasized that the effective characteristics of a phase can be calculated in the usual way when the average fields are uniform. The corresponding equations for a composite sphere and a composite cylinder, structures most frequently used to produce composite materials, are given in the Appendix.

CHOICE OF PERMITTIVITY TENSOR OF COMPARISON BODY. GENERAL PROCEDURE

Equations (1)-(3) will bracket the values of effective permittivities if the upper and lower values of the permittivity of the comparison body ε^c_+ and ε^c_- have been found correctly. It follows from the results of refs. 2 and 3 that the optimum choice of the tensors ε^c_+ and ε^c_- is based on the solution of the inequalities

$$M \leqslant 0, \ N \leqslant 0, \tag{4}$$

where the quadratic forms M and N are defined by the relations

$$\left.\begin{aligned} M \equiv \langle \xi\varepsilon'\xi \rangle, \ N \equiv \langle \eta\gamma'\eta \rangle, \ \xi \equiv \mathbf{E} - \mathbf{E}_0, \\ \eta \equiv \varepsilon^c\xi, \ \varepsilon' = \varepsilon - \varepsilon^c, \ \gamma' = \gamma - \gamma^c, \ \gamma\varepsilon = \gamma^c\varepsilon^c = I. \end{aligned}\right\} \tag{5}$$

Below we use matrix notation, $\mathbf{E}_0$ is the random electric field in the UPF approximation, and $\mathbf{E}$ is a certain piecewise-continuous trial field whose potential at the outer boundary of the body satisfies the condition

$$\varphi - \varphi_0|_S = 0, \ \mathbf{E} \equiv \nabla\varphi_0. \tag{6}$$

It is easy to see that the inequalities (4) are satisfied if

$$\varepsilon' \leqslant 0, \ \gamma' \leqslant 0, \tag{7}$$

from which

$$\varepsilon^c_+ - \varepsilon \geqslant 0, \ \varepsilon - \varepsilon^c_- \geqslant 0. \tag{8}$$

Here, the subscripts + and − denote quantities referring to the upper and lower bounds respectively, and the inequalities are understood in the sense of the positive semidefinite nature of the corresponding quadratic forms.

The inequalities (8) were proposed by Hashin and

Shtrikman.[4] The corresponding bracket for effective permittivities will not be optimum since these inequalities are defined for an arbitrary system of vectors, while the inequalities (4) are defined for a system of vectors satisfying the equations

$$\langle\xi\rangle=\langle\eta\rangle=0, \tag{9}$$

which follow from Eq. (6) after integrating over the surface and using the gradient theorem.[5]

The possibility of narrowing the Hashin–Shtrikman bracket follows from the fact that imposing the subsidiary constraints (9) on the families of quadratic forms M and N compresses the spectrum of eigenvalues of these families (or leaves it unchanged in the degenerate case). Therefore the maximum eigenvalues of these families, determined by the equations

$$\langle\xi(\varepsilon-\varepsilon^c)\xi\rangle=0,\ \langle\eta(\gamma-\gamma^c)\eta\rangle=0, \tag{10}$$

are either decreased or remain unchanged. Consequently, taking account of the subsidiary constraints can narrow the bracket in comparison with the Hashin–Shtrikman bracket.

The electric field of a multiphase polycrystalline aggregate in the UPF approximation is given by

$$\left.\begin{aligned}&\mathbf{E}^\alpha=(I-F^\alpha)^{-1}\Big[\sum_\alpha v_\alpha\int\psi_\alpha(I-F^\alpha)^{-1}\,d\Omega\Big]^{-1}\langle\mathbf{E}\rangle,\\&\mathbf{E}=\mathbf{E}^\alpha(\Omega),\ F^\alpha=F^\alpha(\Omega)=\sum_\beta\int C^{\alpha\beta}(\Omega,\ \Omega_0)\,\varepsilon'^\beta(\Omega_0)\,d\Omega_0,\end{aligned}\right\} \tag{11}$$

where $C^{\alpha\beta}(\Omega, \Omega_0)$ is a certain constant tensor introduced in ref. 1, $\psi_\alpha(\Omega)$ is the texture function of phase α, the indices α and β indicate the number of the phase, and the solid angle Ω determines the orientation of the crystallographic axes. It follows from Eq. (11) that the vector $\mathbf{E}^\alpha(\Omega)$ can be written as the product of a certain tensor, constant for a given phase and chosen orientation of its crystallographic axes, and a constant vector. Therefore the vectors ξ and η can be written in the form

$$\xi^\alpha(\Omega)=H^\alpha(\Omega)\,\xi_*,\ \eta^\alpha(\Omega)=H^\alpha(\Omega)\,\eta_*. \tag{12}$$

Here, $H^\alpha(\Omega)$ is a certain arbitrary tensor, constant for a given phase α and orientation Ω of its crystallographic axes; the symmetry and orientation of the principal axes of the tensor $H^\alpha(\Omega)$ will be determined by the tensor $F^\alpha(\Omega)$, and ξ_* and η_* are arbitrary vectors.

It follows from (12) and (9) that the tensor H^α must satisfy

$$\sum_\alpha v_\alpha\int H^\alpha(\Omega)\,\Psi_\alpha(\Omega)\,d\Omega=0. \tag{13}$$

N-PHASE COMPOSITE

We consider a mixture of N isotropic components. In this case $\Psi_\alpha = (4\pi)^{-1}$, $\varepsilon'_{ij} = \varepsilon'\delta_{ij}$. Then by taking account of Eq. (12) the first of Eqs. (10) gives

$$\sum_\alpha v_\alpha H^\alpha_{i\alpha}H^\alpha_{j\alpha}\varepsilon'_\alpha=0,\ \varepsilon'_\alpha=\varepsilon_\alpha-\varepsilon^c. \tag{14}$$

An analogous equation can be obtained for γ^c. Taking account of the independence of the components H_{ij} and condition (13) it is easy to see that Eqs. (13) and (14) are equivalent to

$$\sum_{\alpha=1}^{N}\rho_\alpha^2 b_\alpha=0,\ \sum_{\alpha=1}^{N}\rho_\alpha=0,\ \rho_\alpha\equiv v_\alpha h_\alpha,\ b_\alpha\equiv\frac{\varepsilon_\alpha-\varepsilon^c}{v_\alpha}, \tag{15}$$

where h_α is an arbitrary scalar, constant within one phase.

By the elimination of ρ_N Eq. (15) can be reduced to the equation for a family of quadratic forms

$$\sum_{\alpha,\beta=1}^{N-1}\rho_\alpha(A_{\alpha\beta}-\varepsilon^c B_{\alpha\beta})\rho_\beta=0, \tag{16}$$

$$A_{\alpha\beta}\equiv\frac{\varepsilon_\alpha}{v_\alpha}\delta_{\alpha\beta}+\frac{\varepsilon_N}{v_N}\theta_{\alpha\beta},\ B_{\alpha\beta}\equiv\frac{1}{v_\alpha}\delta_{\alpha\beta}+\frac{1}{v_N}\theta_{\alpha\beta}, \tag{17}$$

where all the elements of the matrix Θ are unity. Reducing the matrices (17) to triangular form by the Gaussian algorithm[6] we find the secular equation for the eigenvalues ε^c of the family of forms (16)

$$\prod_{\beta=1}^{N}(\varepsilon_\beta-\varepsilon^c)\sum_{\alpha=1}^{N}v_\alpha(\varepsilon_\alpha-\varepsilon^c)^{-1}=0. \tag{18}$$

A similar equation can be obtained for γ^c

$$\prod_{\beta=1}^{N}(\gamma_\beta-\gamma^c)\sum_{\alpha=1}^{N}v_\alpha(\gamma_\alpha-\gamma^c)^{-1}=0. \tag{19}$$

In Eq. (18) all of the ε_α are different. Therefore it determines the eigenvalues ε^c, the largest of which will be smaller than the smallest value found in accord with the first of inequalities (8). Thus taking account of the subsidiary condition (9) decreases the value of ε^c_+ and lowers the upper bound for the effective permittivity.

The same considerations show that the largest of the values of γ^c found from Eq. (19) will be smaller than the smallest value γ^c_- found in accord with the second of the inequalities (8), and consequently the lower bound for ε^* determined by using the permittivity of the comparison body $\varepsilon^c = 1/\gamma^c$ will be larger than that found by using the second of inequalities (8). Thus it has been shown that Eqs. (18) and (19) narrow the Hashin–Shtrikman bracket.

Equations (1), (18), and (19) can be used to bracket ε^* since the singular and the UPF approximations agree for a nontextured mixture of N isotropic components.[1,7]

For a two-phase mixture we find from (18)

$$\varepsilon^c_+=v_1\varepsilon_2+v_2\varepsilon_1=\varepsilon_1\varepsilon_2\langle\varepsilon^{-1}\rangle. \tag{20}$$

Similarly, from Eq. (19) we find ε^c_- determining the lower bound

$$\varepsilon^c_-=(v_1\gamma_2+v_2\gamma_1)^{-1}=\varepsilon_1\varepsilon_2\langle\varepsilon\rangle^{-1}. \tag{21}$$

Equations (20) and (21) agree with those obtained in ref. 2. If $\varepsilon_2 > \varepsilon_1$ they reduce to the inequalities

$$\varepsilon_1<\varepsilon^c_-<\varepsilon^c_+<\varepsilon_2, \tag{22}$$

whereas the Hashin–Shtrikman bracket is determined by $\varepsilon^c_+ = \varepsilon_2$, $\varepsilon^c_- = \varepsilon_1$.

The width of the bracket calculated by Eqs. (1), (20), and (21) is compared with that of the Hashin–Shtrikman bracket in Fig. 1, where ε^+, ε^- and ε^+_{HS}, ε^-_{HS} are plotted

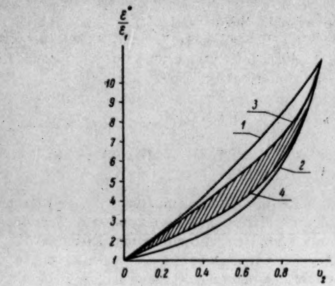

Fig. 1. Bounds for the effective permittivity of a two-component nontextured mixture. 1) $\varepsilon^{+}_{HS}/\varepsilon_1$, 2) $\varepsilon^{-}_{HS}/\varepsilon_1$, 3) $\varepsilon^{+}/\varepsilon_1$, 4) $\varepsilon^{-}/\varepsilon_1$.

as functions of the concentration for $(\varepsilon_2 - \varepsilon_1)/\varepsilon_1 = 10$. It is clear from the figure that the improved bracket can be significantly narrower than the Hashin–Shtrikman bracket (ε^{-}_{HS}, ε^{+}_{HS}).

If the spatial distribution of components is such that the singular and the UPF approximations do not agree, as occurs, for example, for different ordering of the phases of a multicomponent composite, ε^* can be calculated as before by using Eqs. (18) and (19), since they are derived in the more general UPF approximation, but expressing the effective permittivity in terms of ε^c requires replacing (1) by the equation derived in the UPF approximation,[1]

$$\left.\begin{aligned} &\varepsilon^*_{ij} = \varepsilon^c_{ij} + \sum_{\alpha,\beta} v_\alpha v_\beta (X^{-1})^{\alpha\beta}_{ij},\ X^{\alpha\beta}_{ij} = v_\alpha[(p^\alpha_{ij} - q^{\alpha\alpha}_{ij})\delta_{\alpha\beta} + v_\beta q^{\alpha\beta}_{ij}],\\ &p^\alpha_{ij}(\varepsilon^\alpha_{jk} - \varepsilon^c_{jk}) \equiv \delta_{ik},\ q^{\alpha\beta}_{ij} = \int G_{,ij}(\mathbf{r})\varphi^{\alpha\beta}(\mathbf{r})\,d\mathbf{r},\ \varepsilon^c_{ij} = \varepsilon^c\delta_{ij}. \end{aligned}\right\} \quad (23)$$

Here, $G_{,ij}$ is the second derivative of the Green's function of the operator $\varepsilon^c\nabla^2$, and $\varphi^{\alpha\beta}$ is the correlation indicator function.

MULTIPHASE POLYCRYSTALLINE AGGREGATE

We turn now to a discussion of a nontextured multiphase polycrystalline aggregate. In this case the UPF approximation degenerates into the singular. Accordingly we have

$$\left.\begin{aligned} &C^{\alpha\beta}_{ij}(\Omega,\ \Omega_0) = C\delta_{ij}\delta_{\alpha\beta}\delta(\Omega - \Omega_0),\\ &F^\alpha_{ij}(\Omega) = C\varepsilon'^\alpha_{ij}(\Omega),\ C = -\frac{1}{3\varepsilon^c},\ \psi_\alpha = \frac{1}{4\pi}. \end{aligned}\right\} \quad (24)$$

It follows from this that the tensor H^β can be written in the form

$$H^\beta_{ij}(\Omega) = \alpha^\beta_{im}\alpha^\beta_{jm}H^\beta_m. \quad (25)$$

Here the H^β_m are the principal values of the tensor H^β, and the α_{im} are the direction cosines of the principal axes with respect to the laboratory coordinate system.

We now substitute Eq. (25) into (12), and (12) into (10), and use the fact that for an aggregate, averaging is performed over both the phases and the orientations of the crystallographic axes. Then Eq. (10) and condition (13) take the form

$$\left.\begin{aligned} &\sum_\alpha^N\sum_m^3 v_\alpha(H^\alpha_m)^2(\varepsilon^\alpha_m - \varepsilon^c) = 0,\ \sum_\alpha^N\sum_m^3 v_\alpha(H^\alpha_m)^2(\gamma^\alpha_m - \gamma^c) = 0,\\ &\sum_\alpha^N\sum_m^3 v_\alpha H^\alpha_m = 0, \end{aligned}\right\} \quad (26)$$

where the ε^α_m are the principal values of the tensor ε^α, and ε^c is a scalar, since for a quasitropic dielectric the permittivity tensor of the comparison body is also taken to be isotropic.

Comparing Eqs. (26) and (15) we find that the problem of calculating ε^c for an N-phase polycrystalline aggregate reduces to the calculation of ε^c for a 3N-phase composite consisting of isotropic phases. Hence it follows that the solution of Eq. (26) is given by equations analogous to (18) and (19):

$$\prod_{\alpha=1}^N\prod_m^3(\varepsilon^\alpha_m - \varepsilon^c)\sum_\beta^N\sum_n^3 v_\beta(\varepsilon^\beta_n - \varepsilon^c)^{-1} = 0, \quad (27)$$

$$\prod_{\alpha=1}^N\prod_m^3(\gamma^\alpha_m - \gamma^c)\sum_\beta^N\sum_n^3 v_\beta(\gamma^\beta_n - \gamma^c)^{-1} = 0. \quad (28)$$

Equations (27) and (28) are equations of the (3N − 1)-th degree for ε^c and γ^c. The maximum root of Eq. (27) determines ε^c_+, and the maximum root of Eq. (28) gives ε^c_-. Substituting these values of ε^c_+ and ε^c_- into Eq. (2) we obtain the upper and lower bounds for ε^* (ε^+ and ε^-). It is clear that if all the ε^α_n are different the bracket determined this way will be narrower than the Hashin–Shtrikman bracket.

For a single-phase polycrystalline aggregate we find from Eq. (27) that ε^c is given by

$$\left.\begin{aligned} &(\varepsilon^c)^2 - 2\varepsilon^c\langle\varepsilon\rangle + \varepsilon_1\varepsilon_2\varepsilon_3\langle\varepsilon^{-1}\rangle = 0,\\ &\langle\varepsilon\rangle = \frac{1}{3}(\varepsilon_1 + \varepsilon_2 + \varepsilon_3),\ \langle\varepsilon^{-1}\rangle = \frac{1}{3}\left(\frac{1}{\varepsilon_1} + \frac{1}{\varepsilon_2} + \frac{1}{\varepsilon_3}\right). \end{aligned}\right\} \quad (29)$$

The larger of the two roots ε^c of Eq. (29) must be chosen for determining the upper bound. Therefore

$$\varepsilon^c_+ = \max\varepsilon^c = \langle\varepsilon\rangle + (\langle\varepsilon\rangle^2 - \varepsilon_1\varepsilon_2\varepsilon_3\langle\varepsilon^{-1}\rangle)^{1/2}. \quad (30)$$

Similarly from Eq. (28) we find the value of ε^c_- determining the lower bound as the value of the reciprocal of the larger of the roots γ^c.

$$(\varepsilon^c_-)^{-1} = \max\gamma^c = \langle\varepsilon^{-1}\rangle + [\langle\varepsilon^{-1}\rangle^2 - (\varepsilon_1\varepsilon_2\varepsilon_3)^{-1}\langle\varepsilon\rangle]^{1/2}. \quad (31)$$

FILAMENTARY DIELECTRIC

In conclusion we discuss filaments of orthorhombic symmetry oriented along the x_3 axis. One of the axes of second order is parallel to the filament axes, and the other two are oriented arbitrarily. In this case Eq. (25) can be written for the tensor H with the direction cosines α_{ij} determining rotation about the axis of a filament. Substituting Eq. (25) into (12), and (12) into (10), and averaging we obtain a set of equations for ε^c and γ^c:

$$\left.\begin{aligned} &\sum_{\alpha,\,n=1}^2 v_\alpha(H^\alpha_n)^2(\varepsilon^\alpha_n - \varepsilon^c_1) = 0,\\ &\sum_{\alpha,\,n=1}^2 v_\alpha(H^\alpha_n)^2(\gamma^\alpha_n - \gamma^c_1) = 0,\ \sum_{\alpha,\,n=1}^2 v_\alpha H^\alpha_n = 0, \end{aligned}\right\} \quad (32)$$

$$\sum_{\alpha=1}^2 v_\alpha(H^\alpha_3)^2(\varepsilon^\alpha_3 - \varepsilon^c_3) = 0,\ \sum_{\alpha=1}^2 v_\alpha(H^\alpha_3)^2(\gamma^\alpha_3 - \gamma^c_3) = 0,\ \sum_{\alpha=1}^2 v_\alpha H^\alpha_3 = 0. \quad (33)$$

Equation (32) determines the components of the tensors ε^c and γ^c of the comparison body in the plane transverse to the filaments, and Eq. (33) in the direction of the filaments.

Equations (32) and (33) can be put in the form

$$\left.\begin{aligned} v_f \sum_{n=1}^{2} (\varepsilon_n^f - \varepsilon_1^c)^{-1} + 2v_m (\varepsilon_m - \varepsilon_1^c)^{-1} = 0, \\ \varepsilon_{3+}^c = v_f \varepsilon_m + v_m \varepsilon_3^f. \end{aligned}\right\} \quad (34)$$

Analogous equations hold for γ^c

$$\left.\begin{aligned} v_f \sum_{n=1}^{2} (\gamma_n^f - \gamma_1^c)^{-1} + 2v_m (\gamma_m - \gamma_1^c)^{-1} = 0, \\ \frac{1}{\varepsilon_{-3}^c} = \frac{v_f}{\varepsilon_m} + \frac{v_m}{\varepsilon_3^f}. \end{aligned}\right\} \quad (35)$$

Here ε_{1+}^c is equal to the larger of the roots of the quadratic equation (34), and $1/\varepsilon_-^c$ is the larger of the roots of the quadratic equation (35) for γ_1^c. Substituting ε_+^c and ε_-^c into Eq. (3) we obtain the required bracket for $\varepsilon_1{}^* = \varepsilon_2{}^*$. It is clear from Eq. (3) that the third principal value of the effective tensor ε^* is computed exactly.

The variational method discussed above brackets the value of the effective permittivity; greater accuracy evidently requires details of the interactions of the components. The arithmetic mean can be taken as an approximate value of ε^* within the bracket if the interactions of the components are identical; for matrix mixtures the upper bound can be taken if the matrix has a permittivity $\varepsilon_2 > \varepsilon_1$, and the lower bound otherwise. Obviously in special cases when none of the components are simply connected but their interactions are different, the geometric mean of the permittivities ε^+ and ε^- or their reciprocals could be used.

We emphasize that in spite of a certain arbitrariness in the choice of ε^* within the calculated bounds, this procedure leads to better results than the self-consistent method does. In a number of cases the self-consistent method leads to a value of ε^* lying outside our calculated bounds. We show this. The expressions for the self-consistent solution are obtained by setting $\varepsilon^c = \varepsilon^* \equiv \varepsilon^{sc}$. Then the familiar equations of the singular approximation (1)-(3) can be written in the form

$$\langle (\varepsilon - \varepsilon^*)[I - g(\varepsilon - \varepsilon^*)]^{-1} \rangle = 0, \quad (36)$$

where matrix notation has been used, ε is a random tensor, and g is a constant tensor determining the singular part of the second derivatives of the Green's function.[1,2]

Limiting ourselves to a consideration of a two-phase mixture of isotropic components and taking account of the fact that the self-consistent solution always lies within the Voigt–Royce bracket

$$\langle \varepsilon^{-1} \rangle^{-1} \leqslant \varepsilon^{sc} \leqslant \langle \varepsilon \rangle. \quad (37)$$

In addition we note that the effective tensor ε^s is a monotonically increasing function of ε^c. Therefore by using Eq. (1) we can carry out the following mappings of the manifolds ε^c on ε^s:

$$\left.\begin{aligned} \varepsilon^c = [\varepsilon_1, \varepsilon_2] \to \varepsilon^s = [\varepsilon_{HS}^-, \varepsilon_{HS}^+], \\ \varepsilon^c = [\langle \varepsilon^{-1} \rangle^{-1}, \langle \varepsilon \rangle] \to \varepsilon^s = [\varepsilon_0^-, \varepsilon_0^+], \\ \varepsilon^c = \varepsilon^{sc} \to \varepsilon^s \equiv \varepsilon^{sc} \subset [\varepsilon_0^-, \varepsilon_0^+], \\ \varepsilon^c = [\varepsilon_-^c, \varepsilon_+^c] \to \varepsilon^s = [\varepsilon^-, \varepsilon^+]. \end{aligned}\right\} \quad (38)$$

Using the definitions (20) and (21) of the quantities ε_-^c and ε_+^c it is easy to show that

$$\left.\begin{aligned} \varepsilon_-^c < \varepsilon_+^c < \langle \varepsilon^{-1} \rangle^{-1}, \left(0 \leqslant v_1 < \frac{\sqrt{\varepsilon_1}}{\sqrt{\varepsilon_1} + \sqrt{\varepsilon_2}}\right), \\ \langle \varepsilon \rangle < \varepsilon_-^c < \varepsilon_+^c, \left(\frac{\sqrt{\varepsilon_2}}{\sqrt{\varepsilon_1} + \sqrt{\varepsilon_2}} < v_1 \leqslant 1\right). \end{aligned}\right\} \quad (39)$$

Under these conditions $\varepsilon^{sc} \subset [\langle \varepsilon^{-1} \rangle^{-1}, \langle \varepsilon \rangle] \not\subset [\varepsilon_-^c, \varepsilon_+^c]$, and therefore $\varepsilon^{sc} \subset [\varepsilon_0^-, \varepsilon_0^+] \not\subset [\varepsilon^-, \varepsilon^+]$. Thus the self-consistent solution can fall outside the improved bounds calculated by the variational method.

APPENDIX

EFFECTIVE PERMITTIVITY OF A MULTILAYER SPHERE AND CYLINDER

We calculate the effective permittivity of a multilayer dielectric sphere consisting of isotropic layers. Suppose such a sphere is situated in a uniform external field of intensity $\mathbf{E}_0$. Then choosing the origin at the center of the sphere we have for the potential in the α-th layer

$$\varphi_\alpha = -A_\alpha \mathbf{E}_0 \mathbf{r} \left(1 - \frac{C_\alpha}{r^3}\right), \ \alpha = 1, \ldots, N. \quad (A.1)$$

The constants A_α and C_α are found from the condition of continuity of the potential and the normal component of the electric displacement at the interface between the layers. This leads to the following recurrence relations:

$$A_\alpha = A_{\alpha+1} \frac{C_{\alpha+1} - r_\alpha^3}{C_\alpha - r_\alpha^3}, \ C_{\alpha+1} = r_\alpha^3 \frac{(2d_\alpha + 1) C_\alpha + (d_\alpha - 1) r_\alpha^3}{2(d_\alpha - 1) C_\alpha + (d_\alpha + 2) r_\alpha^3}, \quad (A.2)$$

where $d_\alpha = \varepsilon_\alpha \varepsilon_{\alpha+1}^{-1}$, and r_α is the radius of the α-th layer. There must be added the relations $C_1 = 0$ and $A_{N+1} = 1$, which follow from the uniformity of the field in the central spherical layer and the requirement that the field at infinity be $\mathbf{E}_0$.

From Eq. (A.1) we find the average value of the electric displacement and the electric field intensity of a multilayer dielectric sphere:

$$\langle \mathbf{D} \rangle = \sum_{\alpha=1}^{N} v_\alpha \varepsilon_\alpha A_\alpha \mathbf{E}_0, \quad \langle \mathbf{E} \rangle = \sum_{\alpha=1}^{N} v_\alpha A_\alpha \mathbf{E}_0. \quad (A.3)$$

Hence the effective permittivity is

$$\varepsilon^* = \frac{\sum_{\alpha=1}^{N} v_\alpha \varepsilon_\alpha A_\alpha}{\sum_{\alpha=1}^{N} v_\alpha A_\alpha}. \quad (A.4)$$

In the special case of a two-layer sphere we find from this

$$\varepsilon^* = \varepsilon_2 \frac{\varepsilon_1 (1 + 2n) + 2\varepsilon_2 (1 - n)}{\varepsilon_1 (1 - n) + \varepsilon_2 (2 + n)}, \quad n \equiv \frac{r_1^3}{r_2^3}. \quad (A.5)$$

The effective permittivity of a multilayer cylinder is calculated in a similar way. The potential in the α-th layer of a dielectric cylinder is given by

$$\varphi_\alpha = -A_\alpha \mathbf{E}_0 \mathbf{r} \left(1 - \frac{C_\alpha}{r^2}\right). \quad (A.6)$$

The recurrence relations between the constants now take the form

$$\left.\begin{aligned} A_\alpha = A_{\alpha+1} \frac{C_{\alpha+1} - r_\alpha^2}{C_\alpha - r_\alpha^2}, \quad A_{N+1} = 1, \\ C_{\alpha+1} = r_\alpha^2 \frac{(d_\alpha + 1) C_\alpha + (d_\alpha - 1) r_\alpha^2}{(d_\alpha - 1) C_\alpha + (d_\alpha + 1) r_\alpha^2}, \quad C_1 = 0, \end{aligned}\right\} \quad (A.7)$$

and the effective permittivity will as before be given by (A.4).

In the special case of a two-layer cylinder we find

$$\varepsilon^* = \varepsilon_2 \frac{\varepsilon_1(1+m)+\varepsilon_2(1-m)}{\varepsilon_1(1-m)+\varepsilon_2(1+m)}, \quad m \equiv \frac{r_1^2}{r_2^2}. \qquad \text{(A.8)}$$

Resonance properties of a pulsating dielectric sphere

A. G. Nerukh and N. A. Khizhnyak
A. M. Gor'kii Khar'kov State University

(Submitted May 3, 1973)
Zh. Tekh. Fiz., 44, 257-262 (February 1974)

Maxwell's equations in integral form are derived in the first approximation in v/c for a moving inhomogeneous medium allowing for the effect of the motion of the medium on the boundary conditions. A constitutive equation is derived for a dielectric with "quasielastic" molecules and an internal velocity field v(r, t); this equation differs from the Minkowski equations by a term accounting for the inhomogeneity induced in the density of the medium by the motion of the latter. The internal field of a small dielectric sphere of variable radius is determined as an example. It is shown that the internal field is amplified for a harmonic time variation of the radius, corresponding to exchange of energy between the electric field and the moving medium.

1. The solution of electrodynamic problems in moving media depends on the nature of the motion of the medium. For uniform steady motion (the velocity field being described by a constant vector v = const) it is most logical to go over to a comoving reference frame.[1,2] This is the approach used in a study of the propagation of generalized plane waves in a moving isotropic medium.[3]

The electrodynamics of an accelerating medium [for which the uniform velocity field is described by a vector **v**(t) which depends only on the time] can be formulated in general terms by going over to a local coordinate system,[4] although specific problems are treated in the approximation $v/c \ll 1$. Also investigated in ref. 4 is wave propagation in an unbounded uniformly accelerated medium and in a rotating medium. Petrov[5] uses the Maxwell's equations in covariant notation and transforms from a noninertial to an inertial frame to solve the problem of the scattering of a field by a uniformly translating and rotating impedance cylinder. A single comoving reference frame can be introduced in all of these cases.

The latter procedure is impossible in the case of arbitrary nonuniform motion of a medium [**v** = **v**(**r**, t)]. It is possible to analyze some situations,[6,7] such as the nonuniform, tangential, and stationary motion of layers of a medium relative to one another [$\mathbf{v} = \{v_x(z), 0, 0\}$], by using the equations for a uniformly moving medium at each point and considering the entire problem in the laboratory frame.

It is essential to note that the authors of all the foregoing investigations have been compelled to limit the solution of specific problems to the approximation $v/c \ll 1$, an assumption that is justified by the conditions actually encountered in practice.

It is practical to approach the solution of electrodynamic problems in arbitrarily moving media [**v** = **v**(**r**, t)] using the first-order approximation in v/c at the outset. Then the problem can be investigated in the laboratory frame and Maxwell's equations used for the medium at rest, but with the appropriate constitutive equations and boundary conditions.

In the present paper we derive a constitutive equation for a class of dielectrics and solve the problem of the scattering of an electromagnetic wave by a small dielectric sphere of variable radius. We solve the problem by the method of integral equations.[8,9]

2. In the derivation of the constitutive relations we use Maxwell's equations in the form[2,10]

$$\left.\begin{aligned} \operatorname{curl}\mathbf{E} &= -\frac{1}{c}\frac{\partial\mathbf{B}}{\partial t}, \quad \operatorname{div}\mathbf{B}=0,\\ \operatorname{curl}\mathbf{B} &= \frac{1}{c}\frac{\partial\mathbf{D}}{\partial t}, \quad \operatorname{div}\mathbf{D}=0, \end{aligned}\right\} \tag{1}$$

where the medium is characterized by a single electric induction vector D, expressed in terms of the electric (**P**) and magnetic (**M**) polarizations of the medium as follows:

$$\frac{\partial\mathbf{D}}{\partial t}=\frac{\partial\mathbf{E}}{\partial t}+4\pi\left(\frac{\partial\mathbf{P}}{\partial t}+c\operatorname{curl}\mathbf{M}\right). \tag{2}$$

We confine the analysis to a nonmagnetic ($\mu = 1$) dielectric that is nondispersive in the rest state and is composed of "quasielastic molecules," where an irrotational velocity field $\mathbf{v} = c\boldsymbol{\beta}(\mathbf{r}, t)$ is given in the dielectric. We determine the polarization of the medium by averaging the molecular electric moment **p** and magnetic moment **m**. A molecule moving with a velocity **v** has moments $\mathbf{p} = \mathbf{p}_0$ and $\mathbf{m} = [\mathbf{p}_0(\mathbf{v}/c)]$, where $\mathbf{p}_0$ is the dipole moment in the rest state. If the fields **E** and **B** are given in the laboratory frame, then $\mathbf{p}_0 = \alpha(\mathbf{E} + [(\mathbf{v}/c)\mathbf{B}])$, where α is the polarizability of the molecule. Consequently,

$$\mathbf{p}=\alpha\left(\mathbf{E}+\left[\frac{\mathbf{v}}{c}\mathbf{B}\right]\right), \quad \mathbf{m}=\alpha\left[\mathbf{E}\frac{\mathbf{v}}{c}\right]. \tag{3}$$

Averaging (3) by means of the distribution function, we find

$$\left.\begin{aligned} \mathbf{P} &= \alpha n\mathbf{E}+\alpha\frac{1}{c}[\mathbf{qB}],\\ \mathbf{M} &= \alpha\frac{1}{c}[\mathbf{Eq}], \end{aligned}\right\} \tag{4}$$

where $n = \int f\,d\mathbf{v}$ and $\mathbf{q} = \int \mathbf{v}f\,d\mathbf{v}$ are the density and flux of particles of the medium. Assuming that the perturbation of the distribution function f_1 due to the impressed force $\mathbf{F} = c\dot{\boldsymbol{\beta}}$ is small and solving the kinetic equation, we obtain

$$f_1=-c\frac{\partial f_0}{\partial\mathbf{v}}\int_{-\infty}^{t}\dot{\boldsymbol{\beta}}(t', \mathbf{v}, \mathbf{r}-\mathbf{v}(t-t'))\,dt'. \tag{5}$$

We adopt $f_0 = n_0\delta(\mathbf{v})$ as the equilibrium function, calculate n and **q**, substitute the result into (4), and find the following expressions for the polarization moments in terms of the fields:

$$\left.\begin{aligned}\mathbf{P}&=\alpha n_0\left(\mathbf{E}-c\mathbf{E}\int_{-\infty}^{t}\nabla\boldsymbol{\beta}\,dt'+[\boldsymbol{\beta}\mathbf{B}]\right),\\ \mathbf{M}&=\alpha n_0[\mathbf{E}\boldsymbol{\beta}].\end{aligned}\right\} \tag{6}$$

Then the constitutive equation (2) as a function of the fields assumes the form

$$\frac{\partial\mathbf{D}}{\partial t}=\varepsilon\frac{\partial\mathbf{E}}{\partial t}+(\varepsilon-1)\frac{\partial}{\partial t}\left(-c\mathbf{E}\int_{-\infty}^{t}\nabla\boldsymbol{\beta}\,dt'+[\boldsymbol{\beta}\mathbf{B}]\right)+c(\varepsilon-1)\,\mathrm{curl}\,[\mathbf{E}\boldsymbol{\beta}], \tag{7}$$

where $\varepsilon = 1 + 4\pi\alpha n_0$ is the static dielectric constant of the medium.

It will be advantageous below to represent relation (7) in the form D(**E**). Expressing B in terms of **E** by means of Eqs. (1), we have

$$\mathbf{D}=\varepsilon\mathbf{E}-c(\varepsilon-1)\mathbf{E}\int_{-\infty}^{t}\nabla\boldsymbol{\beta}\,dt'-c(\varepsilon-1)\left[\boldsymbol{\beta}\int_{-\infty}^{t}\mathrm{curl}\,\mathbf{E}\,dt'\right]+c(\varepsilon-1)\int_{-\infty}^{t}\mathrm{curl}\,[\mathbf{E}\boldsymbol{\beta}]\,dt'. \tag{8}$$

Equation (8) differs from the familiar Minkowski equations by the presence of the second term on the right-hand side; this term vanishes for an incompressible medium.

3. Before undertaking the solution of the problem of electromagnetic wave scattering by bodies with moving boundaries we take account of the singularities induced in the integral equations by the use of Maxwell's equations in the form (1) and the constitutive equation in the form (8). According to the method of Green's functions,[8,9] the integral equations corresponding to the system (1) have the form

$$\left.\begin{aligned}\mathbf{E}&=\mathbf{E}_0'+\frac{1}{4\pi}\left(\mathrm{grad\,div}-\frac{1}{c^2}\frac{\partial^2}{\partial t^2}\right)\\ &\times\frac{\partial^2}{\partial t^2}\int_{-\infty}^{\infty}dt'\int_{V(t')}\frac{\tau-\frac{1}{c}R}{R}h\left(\tau-\frac{1}{c}R\right)(\mathbf{D}-\mathbf{E})\,d\mathbf{r}',\\ \mathbf{B}&=\mathbf{B}_0'+\frac{1}{4\pi c}\,\mathrm{curl}\,\frac{\partial^3}{\partial t^3}\\ &\times\int_{-\infty}^{\infty}dt'\int_{V(t')}\frac{\tau-\frac{1}{c}R}{R}h\left(\tau-\frac{1}{c}R\right)(\mathbf{D}-\mathbf{E})\,d\mathbf{r}',\end{aligned}\right\} \tag{9}$$

where $\tau = t - t'$, $R = |\mathbf{r}-\mathbf{r}'|$, h(t) is the Heaviside function, and $\mathbf{E}_0'$ and $\mathbf{B}_0'$ are the incident fields corresponding to the medium at rest. Inasmuch as **E** suffers a discontinuity at the boundary and D includes the spatial derivatives of **E**, the differentiation operators must be taken outside the integral sign in order to remove the singularities of the integrand. It is necessary in this case to regard the velocity as a continuous function, as indicated by Pauli.[1] Carrying out the required transformations we obtain the final expression for the integral equation:

$$\begin{aligned}\mathbf{E}&=\mathbf{E}_0+\frac{\varepsilon-1}{4\pi}\left(\mathrm{grad\,div}-\frac{1}{c^2}\frac{\partial^2}{\partial t^2}\right)\frac{\partial^2}{\partial t^2}\\ &\times\int_{-\infty}^{\infty}dt'\int_{V(t')}\frac{\tau-\frac{1}{c}R}{R}h\left(\tau-\frac{1}{c}R\right)\\ &\times\left\{\mathbf{E}-c\mathbf{E}\int_{-\infty}^{t'}\nabla\boldsymbol{\beta}\,dt''-c\left[\mathrm{curl}\,\boldsymbol{\beta}\int_{-\infty}^{t'}\mathbf{E}\,dt''\right]\right.\\ &\left.-c\nabla\boldsymbol{\beta}\int_{-\infty}^{t'}\mathbf{E}\,dt''+2c\left(\int_{-\infty}^{t'}\mathbf{E}\,dt''\nabla\right)\boldsymbol{\beta}\right\}d\mathbf{r}'-\frac{\varepsilon-1}{4\pi}\left(\mathrm{grad\,div}-\frac{1}{c^2}\frac{\partial^2}{\partial t^2}\right)\\ &\times\mathrm{grad}\,\frac{\partial^2}{\partial t^2}\int_{-\infty}^{\infty}dt'\int_{V(t')}\frac{\tau-\frac{1}{c}R}{R}hc\boldsymbol{\beta}\int_{-\infty}^{t'}\mathbf{E}\,dt''\,d\mathbf{r}'\\ &+\frac{\varepsilon-1}{4\pi c}\,\mathrm{curl}\,\frac{\partial^4}{\partial t^4}\int_{-\infty}^{\infty}dt'\int_{V(t')}\frac{\tau-\frac{1}{c}R}{R}\\ &\times h\left\{\left[\boldsymbol{\beta}\int_{-\infty}^{t'}\mathbf{E}\,dt''\right]+\int_{-\infty}^{t'}[\boldsymbol{\beta}\mathbf{E}]\,dt''\right\}d\mathbf{r}'.\end{aligned} \tag{10}$$

The magnetic field is determined from the second relation (9) by spatial integration. By solving Eq. (10) we find the field inside the scattering body.

The integral equation is greatly simplified in the quasistatic case. Thus, if s, the dimension of the body, is much smaller than the characteristic inhomogeneity scale of the field λ, we can neglect the delay inside the body, and we can also neglect the time derivatives in the zeroth approximation in s/λ. Equation (10) assumes the form

$$\begin{aligned}\mathbf{E}&=\mathbf{E}_0+\frac{\varepsilon-1}{4\pi}\,\mathrm{grad\,div}\int_{V(t)}\frac{d\mathbf{r}'}{R}\left\{\mathbf{E}+c\int_{-\infty}^{t}\left(-\mathbf{E}\nabla\tilde{\boldsymbol{\beta}}+[\tilde{\mathbf{E}}\,\mathrm{curl}\,\boldsymbol{\beta}]\right.\right.\\ &\left.\left.+2(\tilde{\mathbf{E}}\nabla)\boldsymbol{\beta}-\tilde{\mathbf{E}}\nabla\boldsymbol{\beta}\right)dt'\right\}-\frac{\varepsilon-1}{4\pi}\,\mathrm{grad\,div\,grad}\int_{V(t)}\frac{d\mathbf{r}'}{R}c\boldsymbol{\beta}\int_{-\infty}^{t}\mathbf{E}\,dt'\end{aligned} \tag{11}$$

Here, the variables with a tilde are to be integrated over t'.

4. As an example we now consider the scattering of a wave by a sphere with a time-varying radius. The strain vector for the elastic sphere can be written with good accuracy[11] in the form $\boldsymbol{\xi} = \xi(t)\mathbf{r}$. The velocity of the medium in this case becomes $\mathbf{v} = \dot{\xi}\mathbf{r}$. Inserting this value into (11) and assuming the field to be uniform inside the sphere, we obtain

$$\mathbf{E}=\mathbf{E}_0-\frac{\varepsilon-1}{3}(1-3\xi(t))\mathbf{E}+\frac{4}{3}(\varepsilon-1)\dot{\xi}(t)\int_{-\infty}^{t}\mathbf{E}\,dt'. \tag{12}$$

The solution of the latter equation has the form

$$\begin{aligned}\mathbf{E}&=\left[\frac{\varepsilon+2}{3}-(\varepsilon-1)\xi(t)\right]^{-1}\mathbf{E}_0\\ &+\frac{4}{3}(\varepsilon-1)\dot{\xi}(t)\left[\frac{\varepsilon+2}{3}-(\varepsilon-1)\xi(t)\right]^{-7/3}\\ &\times\left\{A\mathbf{E}_0+\int_0^{t}\left[\frac{\varepsilon+2}{3}-(\varepsilon-1)\xi(t')\right]^{1/3}\mathbf{E}_0\,dt'\right\},\end{aligned} \tag{13}$$

where the constant A is evaluated from the initial conditions.

We analyze expression (13) for a variation of the sphere radius according to the law $\xi = \xi_0 \sin(\Omega t + \varphi)$. Rewriting the first term in the form

$$\frac{3}{\varepsilon - 3(\varepsilon - 1)\xi(t) + 2}\mathbf{E}_0,$$

we see that it is analogous to the expressions for the internal field of a sphere at rest with an effective dielectric constant $\varepsilon_{\mathrm{eff}} = \varepsilon - 3(\varepsilon - 1)\xi(t)$. The disparity between $\varepsilon_{\mathrm{eff}}$ and ε is caused by the strain-induced inhomogeneity of the material of the sphere.

The second term differs qualitatively from the first term on account of the presence of the integral. Suppose that the strain of the sphere is small ($\xi_0 < 1$) and that the incident field is $\sim e^{i\omega t}$. Clearly, the integrand can be expanded in a series in ξ_0 for a qualitative analysis of the integral. We write the first two terms of the integrated series simultaneously with the factor in front of the braces in (13):

$$\frac{4}{3}(\varepsilon - 1)\xi_0\Omega\cos(\Omega t + \varphi)\left[\frac{\varepsilon + 2}{3} - (\varepsilon - 1)\xi_0 \sin(\Omega t + \varphi)\right]^{-7/3}$$
$$\times\left(\frac{\varepsilon+2}{3}\right)^{1/3}\left\{\frac{e^{i\omega t} - 1}{i\omega}\right.$$
$$-\frac{\varepsilon - 1}{\varepsilon + 2}\xi_0\cos\varphi\left(\frac{i\omega\sin\Omega t - \Omega\cos\Omega t}{\Omega^2 - \omega^2}e^{i\omega t} + \frac{\Omega}{\Omega^2 - \omega^2}\right)$$
$$\left.-\frac{\varepsilon - 1}{\varepsilon + 2}\xi_0\sin\varphi\left(\frac{\Omega\sin\Omega t + i\omega\cos\Omega t}{\Omega^2 - \omega^2}e^{i\omega t} - \frac{i\omega}{\Omega^2 - \omega^2}\right)\right\}. \quad (14)$$

We investigate the resonance case ($\omega \to \Omega$). Passing to the limit in relation (14), we find that the internal field grows as $\sim \Omega t e^{i\psi} \cos(\Omega t + \varphi)$. It also turns out to grow for pulsation of the sphere in a constant field ($\omega = 0$). Since the excited alternating field has the frequency Ω in this case, the resonance condition is always satisfied. The initial phase angle φ is inconsequential here.

It is important in this connection to consider the linear expansion and compression of the sphere ($\mathbf{v} = \xi_0 t\mathbf{r}$) in a constant field $\mathbf{E}_0$. The internal field is

$$\mathbf{E} = \mathbf{E}_0\left(\frac{\varepsilon + 2}{3}\right)^{4/3}\left[\frac{\varepsilon + 2}{3} - \xi_0(\varepsilon - 1)t\right]^{-4/3}, \quad (15)$$

where $\xi_0 = 0$ for $t < 0$ and has a value $\pm\xi_0$ for $t \geq 0$ for expansion and compression, respectively. As we see from (15), the internal field grows in expansion and decays in compression of the sphere, and the two processes are asymmetrical; the growth during expansion is more rapid than the decay during compression. Obviously, this asymmetry also accounts for the growth of the field for a harmonic variation of the sphere radius.

5. The amplification of the field under definite conditions is due to energy exchange between the mechanical motion of the medium and the electromagnetic field. We now show that this feature is also confirmed by an analysis of the energy conservation principle.

The Poynting theorem[12,13] for a stationary nonuniformly moving medium [$\mathbf{v} = \mathbf{v}(\mathbf{r})$] with the density variation ignored has the form

$$-\sigma\mathbf{E}\mathbf{E}_{\mathrm{imp}} = \frac{c}{4\pi}\operatorname{div}[\mathbf{E}\mathbf{H}] + \sigma E^2 + \left(\rho\mathbf{v} + \frac{\sigma\mu}{c}[\mathbf{v}\mathbf{H}]\right)\mathbf{E} + \frac{\partial W}{\partial t}, \quad (16)$$

where σ is the conductivity of the medium, ρ is the density of charges, and W is the electromagnetic energy density, which is defined as

$$W = \frac{1}{8\pi}(\mathbf{E}\mathbf{D}' + \mathbf{B}\mathbf{H}) = \frac{1}{8\pi}\left(\mu H^2 + \varepsilon E^2 - 2\frac{\varepsilon\mu - 1}{c^2}\mathbf{v}[\mathbf{E}\mathbf{H}]\right), \quad (17)$$

where

$$\mathbf{D}' = \varepsilon\mathbf{E} + \frac{\varepsilon\mu - 1}{c}[\mathbf{v}\mathbf{H}].$$

In the absence of impressed field sources ($\mathbf{E}_{\mathrm{imp}} = 0$) expression (16) describes the energy transfer between the medium and the field. The case of a conducting medium has been investigated by Zel'dovich,[14] who found the conditions under which the field is amplified in scattering by a rotating conducting cylinder.

In the case of a nonconducting medium we consider the previous example of a sphere in a constant field with a linearly varying radius. We have from (16)

$$\frac{\partial W}{\partial t} = -\frac{c}{4\pi}\operatorname{div}[\mathbf{E}\mathbf{H}]. \quad (18)$$

Inasmuch as

$$\mathbf{H} = \mathbf{B} + \frac{\varepsilon - 1}{c}[\mathbf{v}\mathbf{E}],$$

we approximately determine the magnetic field induced inside the sphere by the motion of the medium. To do so we substitute the unperturbed field $\mathbf{E}_0$ into the second relation (9) and obtain as a result

$$\mathbf{B} = -\frac{5}{3}\frac{\varepsilon - 1}{c}[\mathbf{v}\mathbf{E}_0]. \quad (19)$$

The expression for the variation of the energy density then acquires the form

$$\frac{\partial W}{\partial t} = \frac{\varepsilon - 1}{3\pi}\xi_0 E_0^2. \quad (20)$$

It is evident from the latter that the field energy will grow or diminish, depending on the direction of motion ($\pm\xi_0$).

Potential factors for an inhomogeneous ellipsoid

M. L. Levin and R. Z. Muratov

(Submitted August 15, 1973)
Zh. Tekh. Fiz., 44, 263-266 (February 1974)

Recursion relations are obtained for internal and external potential factors of an inhomogeneous triaxial ellipsoid; these are expressed in terms of tabulated demagnetization coefficients. The degeneration of an ellipsoid into a spheroid and into a sphere is considered.

The long-standing problem of the field or an inhomogeneous ellipsoid has now emerged from the classical framework of the Newton–Lyapunov treatment, where it was of minor importance and therefore not treated in handbooks and treatises on potential theory. Recently the solution of this problem has become pressing, for example, in the investigation of the dynamics of dense bunches of charged particles,[1,2] and for the construction of an approximate theory of diffraction by small bodies.[3,4]

In the new applications of the problem of the potential of an inhomogeneous body, the inhomogeneity itself is not described in ellipsoidal coordinates, but in ordinary Cartesian coordinates. Therefore the key to the problem is finding the potential of the sources with a power distribution law inside the body. For ellipsoidal bodies the general method of solving this problem was indicated in the 19th century by Ferrers[5] and Dyson.[6] The final closed equations for the source potential with normalized density

$$\rho(x, y, z) = \left(\frac{x}{a}\right)^{\alpha}\left(\frac{y}{b}\right)^{\beta}\left(\frac{z}{c}\right)^{\gamma} \tag{1}$$

(a, b, and c are the ellipsoid semiaxes; α, β, and γ are nonnegative integers) are constructed in ref. 7. Thus, when all the exponents are even ($\alpha = 2\lambda$, $\beta = 2\mu$, $\gamma = 2\nu$), the equation for the potential inside the ellipsoid is of the form

$$\Phi_{2\lambda, 2\mu, 2\nu} = \frac{8\pi}{4^{\sigma}}(2\lambda)!\,(2\mu)!\,(2\nu)! \times \sum_{i=0}^{\sigma}\sum_{j=0}^{\sigma-i}\sum_{k=0}^{\sigma-i-j}\frac{S_{ijk}}{(\sigma-i-j-k)!}x^{2i}y^{2j}z^{2k}\Gamma_{ijk}^{(\lambda,\mu,\nu)}, \tag{2}$$

where

$$\Gamma_{ijk}^{(\lambda,\mu,\nu)} = \sum_{l=0}^{\lambda}\sum_{m=0}^{\mu}\sum_{n=0}^{\nu}\frac{S_{lmn}}{(\lambda-l)!\,(\mu-m)!\,(\nu-n)!}a^{2l}b^{2m}c^{2n}M_{i+l,\,j+m,\,k+n}. \tag{3}$$

Here

$$\left.\begin{gathered}\sigma = \lambda+\mu+\nu+1,\\ S_{lmn} = \frac{(-2)^{l+m+n}}{(2l)!\,(2m)!\,(2n)!},\\ M_{lmn} = (2l-1)!!\,(2m-1)!!\,(2n-1)!!\\ \times\frac{abc}{2}\int_0^{\infty}\frac{du}{(a^2+u)^l(b^2+u)^m(c^2+u)^n\Delta},\\ \Delta^2 = (a^2+u)(b^2+u)(c^2+u).\end{gathered}\right\} \tag{4}$$

We will call the quantities M_{lmn} the internal potential factors of the ellipsoid. We will call the sum $l + m + n$ characterizing the dimensionality of the factor its weight. In particular, the factors of unit weight M_{100}, M_{010}, and M_{001} are the ordinary depolarization coefficients (the demagnetization factors), for which detailed tables exist.[8-10]

The potential outside the ellipsoid (see ref. 11) is described by equations of the form (2) and (3), in which the factors M_{lmn} are replaced by functions of the observation point. These functions (we will call them external potential factors) are obtained from Eq. (4) by replacing the lower limit by the ellipsoidal coordinate of the observation point:

$$\mathcal{M}_{lmn}(\xi) = (2l-1)!!\,(2m-1)!!\,(2n-1)!! \times\frac{abc}{2}\int_{\xi}^{\infty}\frac{du}{(a^2+u)^l(b^2+u)^m(c^2+u)^n\Delta}, \tag{5}$$

where $\xi > 0$ is the maximum root of the equation

$$\frac{x^2}{a^2+\xi}+\frac{y^2}{b^2+\xi}+\frac{z^2}{c^2+\xi} = 1. \tag{6}$$

(Below, we will call the ellipsoid described by Eq. (6) the coordinate ellipsoid.)

To actually use expressions of the type (2) and (3) and similar equations for the potentials outside the ellipsoid we must know the values of the internal and external factors. In this work we introduce recursion relations, which allow us to express all the potential factors in terms of the tabulated demagnetization coefficients M_{100}, M_{010}, and M_{001}.

1. INTERNAL FACTORS OF THE ELLIPSOID

As is known, the demagnetization coefficients of the ellipsoid are interconnected by the relations

$$M_{100}+M_{010}+M_{001} = 1, \tag{7}$$

$$a^2M_{100}+b^2M_{010}+c^2M_{001} = M_{000}. \tag{8}$$

For factors with weight 2 the definition (4) implies the equations

$$\left.\begin{aligned}(a^2-b^2)M_{110} &= M_{010}-M_{100},\\ (b^2-c^2)M_{011} &= M_{001}-M_{010},\\ (c^2-a^2)M_{101} &= M_{100}-M_{001}.\end{aligned}\right\} \tag{9}$$

To derive the general recursion relations we use the fact that the initial definition (4) can be rewritten in the form[7]

$$M_{lmn} = (\hat\partial_a)^l(\hat\partial_b)^m(\hat\partial_c)^n M_{000}, \tag{10}$$

where we have introduced the operator

$$\hat\partial_a = -\frac{\partial}{\partial a}\left(\frac{\dots}{a}\right) = \frac{1}{a^2}-\frac{1}{a}\frac{\partial}{\partial a}. \tag{11}$$

Applying the operator $(\hat\partial_a)^l(\hat\partial_b)^m(\hat\partial_c)^n$ to (7) and (8), we obtain the relations

$$M_{l+1,m,n}+M_{l,m+1,n}+M_{l,m,n+1} = \frac{(2l-1)!!\,(2m-1)!!\,(2n-1)!!}{a^{2l}b^{2m}c^{2n}}, \tag{12}$$

$$a^2M_{l+1,m,n}+b^2M_{l,m+1,n}+c^2M_{l,m,n+1} = (2l+2m+2n+1)M_{lmn}. \tag{13}$$

Application of this same operator to (9) yields the recursion relations

$$\left.\begin{aligned} M_{l+1,m+1,n} &= -\frac{(2m+1)M_{l+1,m,n}-(2l+1)M_{l,m+1,n}}{a^2-b^2}, \\ M_{l,m+1,n+1} &= -\frac{(2n+1)M_{l,m+1,n}-(2m+1)M_{l,m,n+1}}{b^2-c^2}, \\ M_{l+1,m,n+1} &= -\frac{(2l+1)M_{l,m,n+1}-(2n+1)M_{l+1,m,n}}{c^2-a^2}. \end{aligned}\right\} \quad (14)$$

It is clear that these relations do not apply for factors of the form M_{100}, for which two or three indices are equal to zero. Such factors must be transformed beforehand, using (12).

Thus, an arbitrary internal factor of the ellipsoid can be finally expressed in terms of the demagnetization coefficients.

We now consider the degenerate case, in which the ellipsoid is transformed into a spheroid ($a = b \neq c$). Evidently, we have

$$M_{lmn} = M_{mln} \quad (15)$$

and

$$\frac{M_{l+1,m,n}}{2l+1} = \frac{M_{l,m+1,n}}{2m+1}. \quad (16)$$

From Eqs.(12), (13), and (16) it follows that

$$\begin{aligned} &2\frac{l+m+1}{2l+1}(a^2-c^2)M_{l+1,m,n} \\ &= -\frac{(2l-1)!!\,(2m-1)!!\,(2n-1)!!}{a^{2(l+m)}c^{2(n-1)}} + (2l+2m+2n+1)M_{lmn}, \end{aligned} \quad (17)$$

$$\begin{aligned} (a^2-c^2)M_{l,m,n+1} &= \frac{(2l-1)!!\,(2m-1)!!\,(2n-1)!!}{a^{2(l+m-1)}c^{2n}} \\ &\quad -(2l+2m+2n+1)M_{lmn}. \end{aligned} \quad (18)$$

Equations (15), (17), and (18) allow us to express the factors M_{lmn} in terms of an arbitrary demagnetization coefficient of the spheroid $M = M_{001}$.

For a sphere ($a = b = c$), using (12) and (13) we immediately obtain the general equation

$$M_{lmn} = \frac{(2l-1)!!\,(2m-1)!!\,(2n-1)!!}{2(l+m+n)+1}a^{-2(l+m+n-1)}. \quad (19)$$

2. EXTERNAL FACTORS OF THE ELLIPSOID

From the definition (5) of the external factors $\mathcal{M}_{lmn}$ it is clear that an equivalent definition (10) holds for them:

$$\mathcal{M}_{lmn}(\xi) = (\hat{\partial}_a)^l(\hat{\partial}_b)^m(\hat{\partial}_c)^n\mathcal{M}_{000}(\xi).$$

The relations (7) and (8) for factors with unit weight are replaced, as can be easily verified, by

$$\mathcal{M}_{100}+\mathcal{M}_{010}+\mathcal{M}_{001} = \frac{abc}{\sqrt{(a^2+\xi)(b^2+\xi)(c^2+\xi)}},$$

$$a^2\mathcal{M}_{100}+b^2\mathcal{M}_{010}+c^2\mathcal{M}_{001} = \mathcal{M}_{000} - \frac{abc}{\sqrt{(a^2+\xi)(b^2+\xi)(c^2+\xi)}}\xi.$$

Therefore, the external factors are not given by (12) and (13) but by the relations

$$\mathcal{M}_{l+1,m,n}+\mathcal{M}_{l,m+1,n}+\mathcal{M}_{l,m,n+1} = \frac{(2l-1)!!\,(2m-1)!!\,(2n-1)!!\,abc}{(a^2+\xi)^{l+1/2}(b^2+\xi)^{m+1/2}(c^2+\xi)^{n+1/2}}, \quad (20)$$

$$\begin{aligned} &a^2\mathcal{M}_{l+1,m,n}+b^2\mathcal{M}_{l,m+1,n}+c^2\mathcal{M}_{l,m,n+1} \\ &= (2l+2m+2n+1)\mathcal{M}_{lmn} - \frac{(2l-1)!!\,(2m-1)!!\,(2n-1)!!\,abc}{(a^2+\xi)^{l+1/2}(b^2+\xi)^{m+1/2}(c^2+\xi)^{n+1/2}}\xi. \end{aligned} \quad (21)$$

Multiplying (20) by ξ and combining with (21), we rewrite (21) in the more compact form

$$\begin{aligned} &(a^2+\xi)\mathcal{M}_{l+1,m,n}+(b^2+\xi)\mathcal{M}_{l,m+1,n}+(c^2+\xi)\mathcal{M}_{l,m,n+1} \\ &\qquad = (2l+2m+2n+1)\mathcal{M}_{lmn}. \end{aligned} \quad (22)$$

Then, the form of (9) is preserved for the external factors. Hence, the recursion relations (14) also hold for $\mathcal{M}_{lmn}(\xi)$. Together with (20) and (22) these allow us to express the arbitrary external factor $\mathcal{M}_{lmn}(\xi)$ in terms of factors of unit weight $\mathcal{M}_{100}(\xi)$, $\mathcal{M}_{010}(\xi)$, and $\mathcal{M}_{001}(\xi)$. Although the latter are not tabulated, they are, however, very simply connected with the demagnetization coefficients of the ellipsoid. This is a general relation, and holds between the external and internal factors of an ellipsoid in general.

It is established in an elementary way. Actually if in the integral (5) we make the substitution

$$u = u' + \xi,$$

then

$$\mathcal{M}_{lmn}(\xi) = \frac{abc}{a'b'c'}M'_{lmn}, \quad (23)$$

where

$$a' = \sqrt{a^2+\xi}, \quad b' = \sqrt{b^2+\xi}, \quad c' = \sqrt{c^2+\xi},$$

and M'_{lmn} is the internal factor of an ellipsoid with semiaxes a', b', and c', i.e., a coordinate ellipsoid.

Thus, for all l, m, and n the ratio $\mathcal{M}_{lmn}/M'_{lmn}$ is equal to the ratio of the volume of the principal ellipsoid to the volume of the coordinate ellipsoid. Now it is clear that Eqs. (20) and (22) and the recursion relations for $\mathcal{M}_{lmn}(\xi)$ are essentially equivalent to Eqs. (12)-(14), written for the internal factors of the coordinate ellipsoid.

We will not write out the equations referring to the degenerate case of a spheroid, and we present only an expression for the external factor of a sphere:

$$\mathcal{M}_{lmn}(\xi) = \frac{(2l-1)!!\,(2m-1)!!\,(2n-1)!!}{2l+2m+2n+1}\frac{a^3}{r^{2(l+m+n)+1}}. \quad (24)$$

(Submitted April 4, 1973; resubmitted July 24, 1973)
Zh. Tekh. Fiz., 44, 267-272 (February 1973)

The correlation of fluctuating electric fields associated with Bernstein modes in a beam–plasma system is analyzed. The criteria for the kinetic instability of Bernstein modes are analyzed. Certain experimental results are interpreted.

1. STATEMENT OF THE PROBLEM

The excitation of Bernstein modes in a beam–plasma system has been discussed frequently in the literature in attempts to explain experiments on the anomalously intense electromagnetic radiation of a magnetoactive plasma at harmonics of the electron gyrofrequency.[1–7] The complexity of the dispersion relations and of the description of nonlinear effects for Bernstein modes has forced various workers to find instability criteria[3] or to calculate the polarization loss of fast electrons at harmonics of the electron gyrofrequency when there is no instability.[4] The incompleteness of the description in either approach is obvious; the problem requires further analysis.

We restrict the analysis below to the statistical properties of superthermal electric fields due to excitation of Bernstein modes in the beam–plasma system. We interpret certain experimental results[5–8] on this basis. The calculation is carried out by the "random-force" method[9] or the method of "dressed test particles;"[1] we actually calculate the superthermal increment in the electric field caused by a low-intensity beam of fast electrons in the plasma. The plasma is assumed to be infinite and homogeneous.

2. CORRELATION OF ELECTRIC FIELDS IN THE BEAM REGION

According to the method of dressed test particles the motion of electrons in a plasma in an external magnetic field is described by specifying their trajectories: $\mathbf{x}^s(t) = x_0^s + R_H^s \mathrm{Sin}(\omega_H t + \alpha_0^s)$; $y^s(t) = y_0^s + R_H^s \mathrm{Cos}(\omega_H t + \alpha_0^s)$; $z^s(t) = z_0^s + v_\parallel^s t$. The quantities x_0^s, y_0^s, z_0^s, α_0^s, $v_\parallel$, and $R_H^s = v_\perp^s/\omega_H^s$ are random quantities; an averaging will subsequently be carried out over them. Also, $\omega_H = eH/(mc)$ is the electron gyrofrequency, $v_\parallel^s$ and $v_\perp^s$ are the velocity components of electron s, and R_H^s is the electron Larmor radius. The plasma in which the test charge is moving is characterized by a dielectric tensor $\varepsilon_{ij}(\mathbf{k}, \omega)$. The Fourier component of the polarization electric field produced by this charge is[1,10]

$$\mathbf{E}^s(\mathbf{k}, \omega) = \frac{4\pi i\mathbf{k}}{k^2\varepsilon(\mathbf{k}, \omega)}\rho^s(\mathbf{k}, \omega). \tag{1}$$

Here, $\rho^s(\mathbf{k}, \omega) = e\int_{-\infty}^{\infty} \exp[-i\omega t + i\mathbf{k}\mathbf{r}^s(t)]dt$ is the Fourier component of the test-charge density, and $\varepsilon(\mathbf{k}, \omega) = [k_i\varepsilon_{ij}(\mathbf{k}, \omega)k_j]/k^2$ is the longitudinal dielectric constant of the plasma, which governs the dispersion of the electrostatic oscillations.[1,10] Calculating $\rho^s(\mathbf{k}, \omega)$ and using (1), we can write an equation for the autocorrelation function of the electric fields of the test charges in the $(\mathbf{k}, \omega)$ representation: $\langle E_\alpha(\mathbf{k}_1, \omega_1)E_\beta^*(\mathbf{k}_2, \varphi_2)\rangle$ (ref. 1). Since we are interested in only the superthermal increment to the electric fields within the plasma which is caused by the low-intensity electron beam in the plasma, we consider only the beam particles as test particles. Furthermore, we neglect the finite size of the beam region, i.e., we actually analyze the situation within this region. Carrying out the necessary averaging in $\langle E_\alpha(\mathbf{k}_1, \omega_1)E_\beta^*(\mathbf{k}_2, \omega_2)\rangle$ and transforming to the $(\mathbf{r}, t)$ representation, we find

$$\langle E_\alpha E_\beta^*\rangle = \frac{2}{\pi}N_1e^2\int\frac{f_1(\mathbf{v})\,d^3v}{|v_\parallel|}\sum_{m=-\infty}^{\infty}\int d^3k\,d\omega \times \frac{e^{i\omega\Delta t - i\mathbf{k}\Delta\mathbf{r}}k_\alpha k_\beta J_m^2(k_\perp R_H)\,\delta\left(k_\parallel - \frac{\omega - m\omega_H}{v_\parallel}\right)}{k^4|\varepsilon(\mathbf{k}, \omega)|^2}. \tag{2}$$

Here, N_1 is the density of beam particles; $f_1(\mathbf{v})$ is the distribution function of these particles, which satisfies $\int f_1(\mathbf{v})d^3v = 1$; $J_m(x)$ is the Bessel function. Since the system is homogeneous and in the steady state, the correlation function in the $(\mathbf{r}, t)$ representation, $\langle E_\alpha E_\beta^*\rangle$, is a function of only $|\Delta t| = |t_1 - t_2|$ and $|\Delta\mathbf{r}| = |\mathbf{r}_1 - \mathbf{r}_2|$.

In the case of slightly damped plasma waves in an equilibrium, magnetoactive, collisionless plasma, $\mathrm{Re}\,\varepsilon_0$ and $\mathrm{Im}\,\varepsilon_0$ are given by[1–4,11]

$$\mathrm{Re}\,\varepsilon_0(\mathbf{k}, \omega) = 1 - 2\left(\frac{\omega_p}{\omega_H}\right)^2\sum_{l=1}^{\infty}I_l(\lambda)\frac{e^{-\lambda}}{\lambda}\frac{l^2}{\left[\left(\frac{\omega}{\omega_H}\right)^2 - l^2\right]}, \tag{3}$$

$$\mathrm{Im}\,\varepsilon_0(\mathbf{k}, \omega) = \sqrt{\pi}\left(\frac{\omega_p}{\omega_H}\right)^2\alpha_0\sum_{l=-\infty}^{\infty}I_l(\lambda)\frac{e^{-\lambda}}{\lambda}e^{-\alpha_l^2}, \tag{4}$$

where $\lambda = (k_\perp r_H)^2$; $r_H = v_0/\omega_H$; $v_0 = \sqrt{T/m}$; and $\alpha_l = |(\omega - l\omega_H)/\sqrt{2}v_0k_\parallel|$.

The condition for small damping is $\alpha_l^2 \gg 1$; this condition can evidently be satisfied by choosing sufficiently small $k_\parallel$. It can be shown that a sufficient criterion is[3] $|k_\parallel| \ll k_\perp$. According to (2), the value of $k_\parallel$ is given by the "radiation condition" $k_\parallel = (\omega - m\omega_H)/v_\parallel$. If $\omega \approx m\omega_H$, the condition $(\alpha_l^m)^2 \gg 1$, which must hold for all l, is most sensitive to the term with $m = l$ in (4). For this term we must have $v_\parallel^2/(2v_0^2) \gg 1$. This result shows that only fast (superthermal) electrons can generate slightly damped Bernstein modes.

In an actual calculation on the basis of Eq. (2), taking Eqs. (3) and (4) into account, comparatively simple and graphic equations can be found only in the case $\omega_p^2 < \omega_H^2$, in which all branches of the Bernstein-mode dispersion curves are near and above each harmonic n of the gyrofrequency: $\Delta\omega_n(k_\perp) \equiv \omega_n(k_\perp) - n\omega_H \ll \omega_H$ (refs. 1-3, 11). In this case we need retain in Eq. (3) only the one term with $l = n$. Furthermore, if $[v_\parallel/\sqrt{2}v_0]^2 \gg 1$, but $[v_\parallel\Delta\omega_n(k_\perp)/(\sqrt{2}v_0\omega_H]^2 \lessdot 1$, we need retain only the one term with $l = m = n$ in Eqs. (2) and (4). We then find

$$\langle E_\alpha E_\beta^*\rangle = 4N_1 e^2 \int \frac{f_1(\mathbf{v})\, d^3v}{\eta(v_\parallel)\,|v_\parallel|} \sum_{n=1}^{\infty} \int d\mathbf{k}_\perp dk_\parallel \frac{k_\alpha k_\beta}{k^4} J_n^2(k_\perp R_H)\, \Delta\omega_n(k_\perp)$$

$$\times e^{i\omega_n(k_\perp)\Delta t - |\gamma_n(k_\perp)\Delta t| - i\mathbf{k}\Delta\mathbf{r}} \delta\left(k_\parallel - \frac{\Delta\omega_n(k_\perp)}{v_\parallel}\right), \qquad (5)$$

where

$$\left.\begin{aligned} &\Delta\omega_n(k_\perp) = n\omega_H \left(\frac{\omega_p}{\omega_H}\right)^2 I_n(\lambda)\frac{e^{-\lambda}}{\lambda}; \quad \gamma_n(k_\perp) = \eta(v_\parallel)\,\Delta\omega_n(k_\perp); \\ &\eta(v_\parallel) = \frac{\sqrt{\pi}}{2}\left|\frac{v_\parallel}{v_0}\right| \exp\left(-\frac{v_\parallel^2}{2v_0^2}\right) \ll 1; \quad d\mathbf{k}_\perp \equiv k_\perp dk_\perp d\Phi. \end{aligned}\right\} \qquad (6)$$

The summation is carried out over all the Bernstein modes.

We turn to an analysis of Eq. (5). a) Since $k_\parallel = [\Delta\omega_n(k_\perp)]/v_\parallel < \omega_H/v_\parallel$, and since typically[11,12] $k_\perp \sim r_H^{-1}$, we have $k_\parallel/k_\perp < v_0/v_\parallel \ll 1$. Accordingly, the autocorrelation function for the field components E_α and E_β along H is small in comparison with that of the normal components.

b) The spatial-correlation radius is given, according to (5), by $|\Delta r_\perp| \sim k^{-1} \sim R_H$; $|\Delta z| \sim k_\parallel^{-1} > k_\perp^{-1}\ (v_\parallel/v_0) \sim R_H(v_\parallel/v_0) \gg R_H$. The explanation for this result is that the test particles are completely uncorrelated, and the correlation radius for the electric fields in the plane perpendicular to H is governed by the Larmor radii of the individual particles, R_H. The correlation radius along H turns out to be much larger than R_H, because in this approximation the particles move without collisions along H, retaining their "initial phases."

c) The purely temporal ($\Delta r = 0$) correlation of the fields is governed, according to Eqs. (5) and (6), by the ranges of the frequency $\omega_n(k_\perp)$ in the integrals over $dk_\perp$ and by the relative weights of the terms in the summation over n. A numerical calculation shows that in the case under consideration here ($\omega_H^2 > \omega_p^2$) the term with n = 1 is important; the second term is an order of magnitude lower; etc. This behavior is in accordance with the circumstance that the "passband" $\Delta\omega_n(k_\perp)$ in the integrand becomes rapidly narrower with increasing harmonic index in the case $\omega_p^2 < \omega_H^2$ (refs. 1-4, 11). The correlation time $\Delta t \sim 1/[\Delta\omega_n(k_\perp)]$ turns out to be equal to several periods of the electron gyration, since $\Delta\omega_n(k_\perp) < \omega_H$. In the case $\omega_p^2 > \omega_H^2$ the passband is $\Delta\omega_n(k_\perp) \sim \omega_H$, and correlation time $\Delta t \sim 1/\omega_H$ turns out to be shorter than in the case $\omega_p^2 < \omega_H^2$).

d) Up to this point we have neglected the collisional damping of Bernstein modes. As a result we find the small factor $\eta(v_\parallel)$ in the denominator in (5), which comes from $\mathrm{Im}\,\varepsilon_0(\mathbf{k}, \omega_n(\mathbf{k}))$. At sufficiently large values of $v_\parallel$ the Bernstein modes are "radiated by the test particles" at very small angles with respect to the normal to the magnetic field: $k_\parallel/k_\perp \ll 1$. Accordingly, we have $\alpha_\xi^2 \gg 1$ in $\mathrm{Im}\,\varepsilon_0(\mathbf{k}, \omega)$, so the collisionless-damping factor becomes smaller than the collisional factor. The collisional damping of Bernstein modes has not been studied adequately. Works which have appeared on this question[12] do not furnish a basis for calculating the corresponding damping factor. As a rough estimate we can set $\gamma_{st} \sim \nu_{ei}$, where ν_{ei} is the effective frequency of electron–ion collisions, although this estimate could be too high in the case $\omega_p^2 < \omega_H^2$. According to (5), the maximum value of $\sqrt{\langle E^2\rangle}$ is governed by the minimum possible value of $\eta(v_\parallel^*)$, which in turn is found from the condition $\gamma_n(k_\perp) = \eta(v_\parallel^*) \times \Delta\omega_n(k_\perp) \geqslant \nu_{ei}$. This condition determines the optimum values of $v_\parallel^*$.

e) We have also neglected the contribution of the beam distribution function $f_1(\mathbf{v})$ to $\mathrm{Im}\,\varepsilon(\mathbf{k}, \omega)$. Within the framework of the method of dressed test particles we must require $|\mathrm{Im}\,\varepsilon_1(\mathbf{k}, \omega) < |\mathrm{Im}\,\varepsilon_0(\mathbf{k}, \omega)|$, in order to avoid a possible instability. As is shown in Sec. 4 below, this condition can be formulated approximately as $N_1/N_0 < \exp[-v_\parallel^2/2v_0^2]$.

On the basis of this analysis we can determine conditions under which the nonthermal increment to the electric fields due to the excitation of Bernstein modes reaches its maximum value, and we can estimate some values. For example, choosing $N_0 = 10^{13}$ cm^{-3}, we find $\omega_p = 2\cdot 10^{11}$ sec^{-1}. Then choosing $\omega_H = 1.5\,\omega_p = 3\cdot 10^{11}$ sec^{-1}, T = 1 eV, and $v_0 = 4\cdot 10^7$ cm/sec, we find, according to paragraph d), $\nu_{ei} \sim 5\cdot 10^8$ sec^{-1} and $\eta_{\min}(v_\parallel^*) = 2\cdot 10^{-3}$, which correspond to $v_\parallel^* = 4v_0 = 16\cdot 10^7$ cm/sec and $N_{1\max} \sim 10^{-3}N_0 \sim 10^{10}$ cm^{-3}. For these parameter values we have $\langle E^2\rangle_{\max} \sim 10^{-3}$ Oe/cm^3 and $\sqrt{\langle E^2\rangle} \approx 3\cdot 10^{-2}$ Oe$^{1/2}\cdot$cm$^{-3/2} \approx$ 10/V cm. The strength of the thermal fields, evaluated from the equation for an isotropic plasma,[1,9] $\langle E^2\rangle/N_0T \sim (2\pi N_0 L_d^3)^{-1}$, turns out to be on the same order of magnitude.

3. ACCOUNT OF THE FINITE TRANSVERSE DIMENSIONS OF THE BEAM. FIELD CORRELATION FAR FROM THE BEAM

Again we assume the plasma to be infinite and homogeneous, characterizing it by $\varepsilon_0(\mathbf{k}, \omega)$. In this statement of the problem we can take account of the finite size of the beam region in the direction transverse to H and analyze the correlation of the electric fields due to Bernstein modes outside the region in which these modes are generated. As a result we find an equation for $\langle E_\alpha E_\beta^*\rangle$ in the $(\mathbf{r}, t)$ representation which is analogous to Eq. (5), but in which the integrand in the integral over $d\mathbf{k}_\perp$ is multiplied by the function

$$F_n(\mathbf{r}_\perp, \mathbf{k}_\perp) = \frac{a^2}{2\pi} \int d\Delta\mathbf{k}_\perp \frac{J_1(a|\Delta\mathbf{k}_\perp|)}{a|\Delta\mathbf{k}_\perp|} e^{-\mathbf{r}_\perp\Delta\mathbf{k}_\perp}$$

$$\times \left\{1 - i\mathbf{k}_\perp\cdot\Delta\mathbf{k}_\perp \frac{dg_n(k_\perp^2)}{dk_\perp^2}[g_n(k_\perp^2)\,\eta(v_\parallel)]^{-1}\right\}^{-1}, \qquad (7)$$

where a is the radius of the cylindrical beam, $\mathbf{k}_\perp = (1/2)(\mathbf{k}_{1\perp} + \mathbf{k}_{2\perp})$; $\Delta\mathbf{k}_\perp = \mathbf{k}_{1\perp} - \mathbf{k}_{2\perp}$; $g_n(k_\perp^2) = I_n(\lambda)e^{-\lambda}\lambda^{-1}$; $\lambda = k_\perp^2 r_H^2$. Since $|\mathbf{k}_{1\perp}| \sim |\mathbf{k}_{2\perp}| \sim r_H^{-1}$ and since we effectively have $|\Delta\mathbf{k}_\perp| \sim a^{-1}$, where we are assuming $a \gg r_H$, we find $|\Delta\mathbf{k}_\perp/\mathbf{k}_\perp| \sim r_H/a \ll 1$. As $a \to \infty$ we find $F_n(\mathbf{r}_\perp, \mathbf{k}_\perp) \to 1$, and we again find Eq. (5).

The correlation function $\langle E_\alpha E_\beta^*\rangle$ taking $F_n(\mathbf{r}_\perp, \mathbf{k})$ into account is a function of Δt, $\Delta\mathbf{r}$, and $\mathbf{r}_\perp$, the distance from the beam axis. The factor for the propagation of Bernstein modes away from the beam axis takes $F_n(\mathbf{r}_\perp, \mathbf{k}_\perp)$ into account. We see from the structure of $F_n(\mathbf{r}_\perp, \mathbf{k}_\perp)$ that the quantity

$$L_d^{(n)r}(k_\perp) = \left|k_\perp - \frac{dg_n(k_\perp^2)}{dk_\perp^2}[g_n(k_\perp^2)\,\eta(v_\parallel)]^{-1}\right|$$

serves as the damping length for Bernstein mode n with specified $k_\perp$. This quantity is equal to that calculated from the familiar equation:[10] $L_d(k) = v_g(k)/\gamma(k) = \partial\omega(k)/\partial k\gamma^{-1}(k)$, where $\omega(k)$ and $\gamma(k)$ must be written in accordance with Eq. (6). Bernstein modes are observed outside the beam if $L_d^{(n)}(k_\perp) \gg a$, but this condition cannot be satisfied at all wavelengths. As is evident from the dispersion curves,[1-3] there are regions of $k_\perp$ in which $\partial\omega/(\partial k_\perp) \approx 0$. We restrict the discussion here to the particular case for which Eq. (5) is derived. According to paragraph c of Sec. 2, only the harmonic with n = 1 is important in this equation. The dispersion curves for the first Bernstein mode show that the low group velocities are found at $k_\perp r_H \ll 1$; over a broader part of the passband, on the other hand, where $k_\perp \sim r_H^{-1}$, we have $v_g \sim v_0$, with $\partial\omega^{(1)}(k_\perp^2)/(\partial k_\perp^2) < 0$, corresponding formally to a "negative group velocity."[1] Accordingly, the condition $L_d^{(1)}(k_\perp) \gg a$ can be satisfied for nearly all wavelengths. For example, with $v_0 = 4 \cdot 10^7$ cm/sec and $H = 10^3$ G we find $r_H \simeq 10^{-3}$ cm, while with $\eta(v_\parallel) \simeq 10^{-3}$ we find $L_d^{(1)} \sim$ 1 cm. Let us examine the behavior of $\langle E_\alpha E_\beta^*\rangle$ outside the beam: $r_\perp \gg a$ (for $L_d^{(1)} \gg a$). We evaluate $F_1(\mathbf{r}_\perp, \mathbf{k}_\perp)$ and use the result for the integration in (5) over Φ in the integral over $d\mathbf{k}_\perp = k_\perp dk_\perp d\Phi$. Here the k_x axis in $\mathbf{k}_\perp$ space is directed along $\mathbf{r}_\perp$, while we have $k_y \parallel \mathbf{r}_\perp$. We find

$$\langle E_x E_x^*\rangle \sim \left(\frac{a}{r}\right)\exp\left[-\frac{r_\perp}{L_d^{(1)}(k_\perp)}\right];$$

$$\langle E_y E_x^*\rangle \sim \left(\frac{a}{r}\right)^2\exp\left[-\frac{r_\perp}{L_d^{(1)}(k_\perp)}\right];$$

$$\langle E_y E_y^*\rangle \sim \left(\frac{a}{r}\right)^3\exp\left[-\frac{r_\perp}{L_d^{(1)}(k_\perp)}\right].$$

There is an interesting feature in the space–time correlation of the fields in the case $r_\perp \gg a$, $L_d^{(1)} \gg a$. It turns out that, since $[\partial\omega^{(1)}(k_\perp^2)]\,(\partial k_\perp^2) < 0$, an important role in the integral over $d\Phi$ is played by angles $\Phi \approx \pi$, i.e., $\mathbf{k}_\perp$ is antiparallel to $\mathbf{r}_\perp$. If we choose $\Delta \mathbf{r}_\perp \parallel \mathbf{r}_\perp$ we find that the factor $\exp[i\omega^{(1)}(k_\perp)\Delta t + k_\perp \Delta r_\perp]$ in Eq. (5) characterizes a wave process in which the phase surfaces move in the direction opposite $\Delta\mathbf{r}_\perp$, i.e., toward the beam axis.

4. KINETIC INSTABILITIES OF THE BEAM IN A PLASMA WITH RESPECT TO EXCITATION OF BERNSTEIN MODES

Tataronis and Crawford[3] analyzed hydrodynamic instabilities of a system consisting of a Maxwellian plasma and a "cold" beam, $f_1(\mathbf{v}) = 1/2\pi v_\perp^*)\,[\delta(v_\parallel - v_\parallel^*)\,\delta(v_\perp - v_\perp^*)]$, in the frequency intervals between harmonics of the electron gyrofrequency. The hydrodynamic stage in the beam relaxation is rapidly replaced by a kinetic stage,[13] so it is interesting (particularly in the case of steady-state injection) to study the development of instabilities at harmonics of the gyrofrequency for a beam having a thermal spread. We therefore write $f_1(\mathbf{v})$ as

$$f_1(\mathbf{v}) = \alpha\,\frac{\exp\left[-\left(\frac{v_\parallel - v_\parallel^*}{\Delta v_\parallel}\right)^2 - \left(\frac{v_\perp - v_\perp}{\Delta v_\perp}\right)^2\right]}{2\pi^2\xi\Delta v_\parallel \Delta v_\perp^2}, \tag{8}$$

where $\alpha = N_1/N_0 \ll 1$; $\xi = v_\perp^*/\Delta v_\perp \gg 1$; $v_\parallel^*/\Delta v_\parallel \gg 1$; $v_\parallel^*/v_\perp^* \gg 1$; and $\int f_1(\mathbf{v})d^3v = \alpha$.

Beams like that described approximately by $f_1(\mathbf{v})$ in (8) have been produced experimentally.[5-8] To calculate $\mathrm{Im}\,\varepsilon_1(\mathbf{k}, \omega)$ with $f_1(\mathbf{v})$ and to compare it with $\mathrm{Im}\,\varepsilon_0(\mathbf{k}, \omega)$, we use the standard equations,[1-3,10,11] finding

$$\mathrm{Im}\,\varepsilon_1(\mathbf{k}, \omega) = \frac{2\sqrt{\pi}\,\omega_p^2\alpha}{k^2|k_\parallel|(\Delta v_\parallel)^3}\sum_{l=-\infty}^{\infty} e^{-\left(\frac{\omega - l\omega_H - k_\parallel v_\parallel^*}{k_\parallel \Delta v_\parallel}\right)^2} \times J_l^2\left(\frac{k_\perp v_\perp^*}{\omega_H}\right)(\omega - l\omega_H - k_\parallel v_\parallel^*). \tag{9}$$

In deriving (9) we assumed $k_\perp \Delta v_\perp \ll \omega_H$. Since $k_\perp \sim r_H^{-1}$ for Bernstein modes, this condition implies $\Delta v_\perp \ll v_0$. Since there is a magnetic field, the case $\Delta v_\parallel \gg \Delta v_\perp$ is possible.

Comparison of Eqs. (9) and (4) shows that for the harmonic with $\omega(k_\perp) \simeq l\,\omega_H$ the values of $k_\parallel = [\omega(k_\perp) - l\,\omega_H]/v_\parallel$ found from the "radiation condition" cause an exponentially weak damping of waves in a Maxwellian plasma, $\mathrm{Im}\,\varepsilon_0 \sim \exp[-v_\parallel^2/(2v_0^2)] \ll 1$ [see Eq. (6)], but the corresponding exponential function in $\mathrm{Im}\,\varepsilon_1$ is not small:

$$\exp\left[-\left(\frac{\omega - l\omega_H}{k_\parallel \Delta v_\parallel} - \frac{v_\parallel^*}{\Delta v_\parallel}\right)^2\right] = \exp\left[-\left(\frac{v_\parallel - v_\parallel^*}{\Delta v_\parallel}\right)^2\right] \leqslant 1.$$

Accordingly, to satisfy the condition $|\mathrm{Im}\,\varepsilon_1| < |\mathrm{Im}\,\varepsilon_0|$ we can write the approximate criterion $\alpha = N_1/N_0 < \exp[-v_\parallel^2/(2v_0^2)]$. The sign of $\mathrm{Im}\,\varepsilon_1$ is governed by the quantities in the brackets in (9) and can be either positive or negative. When $|\mathrm{Im}\,\varepsilon_1| > |\mathrm{Im}\,\varepsilon_0|$, an instability develops in the region $\mathrm{Im}\,\varepsilon_1 < 0$. Stone and Auer[4] have calculated the rate at which fast electrons are lost due to excitation of Bernstein modes by the method of dressed test particles. Comparison of this theory with experiment[7] shows that it is necessary to postulate a group of particles with $v_\perp^* \sim 4v_0$ and $\alpha \sim 0.1$ in the plasma in order to explain the observed intensity of the radiation at the harmonics and to explain the observed spectral characteristics (under the assumption of a 100% transformation of Bernstein modes into electromagnetic waves). However, an instability should develop under these conditions, since we have $\exp[-v_\parallel^2/(2v_0^2)] \sim 10^{-3}$. Apparently an instability with respect to the excitation of Bernstein modes develops in all experiments carried out to observe radiation at harmonics, so it becomes a theoretical problem to explain the intensity of this radiation.

Idehara et al.[6] measured the intensity of the radiation at the harmonics as a function of the path length traveled by the beam in the plasma during steady-state injection, z. In the region z < z* they observe a rapid increase in the intensity; at z = z* they observe saturation and then a comparatively slower decay. Equation (9) yields a qualitative explanation for this behavior. This behavior reflects primarily the course of the beam relaxation due to excitation of numerous branches of waves, even when the situation is clearly not one-dimensional ($\omega_p > \omega_H$). The theoretical relaxation models of ref. 14 therefore cannot be used, but we can assume that the relaxation consists of an increase in the values $\Delta v_\parallel$ and $\Delta v_\perp$ in (8) with increasing z (unfortunately, the corresponding experimental data are not given in ref. 6). The factor governing the amplitude of Bernstein modes, which is proportional to $\mathrm{Im}\,\varepsilon_1(\mathbf{k}, \omega)$ according to (9), behaves in the following manner: For $z < z^*(\Delta v_\parallel < \Delta v_\parallel^*)$ the minimum arguments of the exponential functions in (9) are larger than unity, but the increase in $\Delta v_\parallel$ with increasing z leads to a rapid increase in the factor and to its saturation at $z = z^*$ and $\Delta v_\parallel = \Delta v_\parallel^*$, at which point the minimum arguments are again on the order of unity. With a further increase in

$\Delta v_{\parallel}$ and $\Delta v_{\perp}$, there is a slower (power-law) decrease in the factor.

We note that the approximate criterion for kinetic instability of the beam with respect to the excitation of Bernstein modes which we found above, $N_1/N_0 > \exp[-v_{\parallel}^2/(2v_0^2)]$, is not affected by the relation between ω_p and ω_H. This situation is characteristic of a hydrodynamic instability, which has been predicted[3] only for $\omega_p^2 > \omega_H^2$. Incidentally, in certain experiments[8] the instability at the harmonics develops even with $\omega_p^2 < \omega_H^2$.

In conclusion the author thanks A. S. Grebinskii, A. Z. Dolginov, A. D. Piliya, V. I. Federov, and D. G. Yakovlev for several discussions of this work.

Plasma

Excitation of electromagnetic ion cyclotron waves by fast ions

T. D. Kaladze, D. G. Lominadze, and K. N. Stepanov

(Submitted May 16, 1973)
Zh. Tekh. Fiz., 44, 273-276 (February 1974)

The growth rate is computed for ion cyclotron waves that propagate across the magnetic field in a deuterium plasma. The waves are excited by a low-density beam of fast ions that result from fusion reactions.

The presence of fast monoenergetic ions (products of fusion reactions) leads to various plasma instabilities.[1-8] In a low-pressure plasma the largest growth rates correspond to electrostatic plasma oscillations[2] and fast magnetoacoustic waves[8] propagating nearly at right angles to the magnetic field. The electrostatic oscillations considered in ref. 2 are excited only when $\beta \leqslant 10^{-3}$. The fast magnetoacoustic waves considered in ref. 8 are not an isolated branch at $\beta \geqslant 0.1$ but represent segments of the ion cyclotron modes.[9,10]

In the present paper we use the analysis of ion cyclotron modes of ref. 10 to investigate excitation of these modes by fast monoenergetic ions. We show that the growth rate for these modes is of the same order as those considered in refs. 2 and 8:

$$\gamma = \eta\left(\frac{n_0'}{n_0}\right)^{1/3}\omega_{Bi}, \tag{1}$$

where n_0' and n_0 are the densities of the fast and cold ions, respectively.

The dispersion relation for extraordinary waves propagating at right angles to the magnetic field is

$$(\varepsilon_1+\delta\varepsilon_1)N^2-(\varepsilon_1+\delta\varepsilon_1)(\varepsilon_1'+\delta\varepsilon_1')+(\varepsilon_2+\delta\varepsilon_2)^2=0, \tag{2}$$

where $N = kc/\omega$ is the refractive index. In the absence of the fast ions the components of the permittivity tensor ε_i are

$$\varepsilon_1=-\frac{\omega_{pi}^2}{\omega}\sum_{n=-\infty}^{\infty}\frac{a_1}{\omega-n\omega_{Bi}},$$

$$\varepsilon_1'=-\frac{\omega_{pi}^2}{\omega}\sum_{n=-\infty}^{\infty}\frac{a_1'}{\omega-n\omega_{Bi}},$$

$$\varepsilon_2=-\frac{\omega_{pe}^2}{\omega\omega_{Be}}-\frac{\omega_{pi}^2}{\omega}\sum_{n=-\infty}^{\infty}\frac{a_2}{\omega-n\omega_{Bi}},$$

where

$$a_1=\frac{n^2}{x^2}e^{-x^2}I_n(x^2),$$

$$a_1'=\left[\frac{n^2}{x^2}I_n(x^2)+2x^2(I_n(x^2)-I_n'(x^2))\right]e^{-x^2},$$

$$a_2=n\left[I_n'(x^2)-I_n(x^2)\right]e^{-x^2},$$

$x = k\rho_i$, $\rho_i = v_{Ti}/\omega_{Bi}$ is the ion Larmor radius for the thermal velocity $v_{Ti} = (T_i/m_i)^{1/2}$, $I_n(x^2)$ is the modified Bessel function and I_n' is the derivative.

The contribution of the fast monoenergetic ions to the components of the permittivity tensor is determined by the relations

$$\delta\varepsilon_1=\frac{\omega_p'^2}{k^2v_0^2}-\frac{\omega_p'^2}{\omega_B'}\sum_{n=-\infty}^{\infty}\frac{b_1}{\omega-n\omega_B'},$$

$$\delta\varepsilon_1'=-\frac{\omega_p'^2}{\omega_B'}\sum_{n=-\infty}^{\infty}\frac{b_1'}{\omega-n\omega_B'}-\delta\varepsilon_1,$$

$$\delta\varepsilon_2=-\frac{\omega_p'^2}{\omega_B'}\sum_{n=-\infty}^{\infty}\frac{b_2}{\omega-n\omega_B'},$$

where

$$b_1=\frac{4}{A^2}\frac{\omega}{\omega_B'}J_{2n}(A),$$

$$b_1'=\frac{1}{A}\frac{\omega_B'}{2\omega}\left\{A\left[J_{2(n-1)}(A)+J_{2(n+1)}(A)\right]\right.$$

$$\left.+\int_0^A\left[J_{2(n-1)}(y)+J_{2(n+1)}(y)\right]dy\right\},$$

$$b_2=\frac{2}{A}J_{2n}'(A),\quad A=\left(\frac{2kv_0}{\omega_B'}\right),$$

J_{2n} is the Bessel function, $\omega'_p = (4\pi z'e^2n_0'/m')^{1/2}$ is the plasma frequency of the fast ions, $\omega'_B = z'eB_0/(m'c)$ is the cyclotron frequency of the fast ions, and v_0 is the velocity (we ignore the thermal energy spread $\sim T_i$ of the fast ions compared with $m'v_0^2/2$).

In the zeroth approximation ($n'_0 \to 0$), the dispersion relation (2) has solutions $\omega = \omega^{(j)}(k)$, where $(j-1)\omega_{Bi} < \omega^{(j)} < j\omega_{Bi}$ ($j = 1, 2 \ldots$), corresponding to cyclotron waves in the plasma (see refs. 9 and 10) and solutions corresponding to cyclotron oscillations of the fast ions: $\omega = n\omega'_B$. An instability arises when $n'_0 \ll n_0$ in the intersection region of these curves $k \approx k_0$, where $\omega^{(j)}(k_0) = n\omega'_B$.

Setting $\omega = \omega^{(j)}(k) + \Delta\omega$, where $\Delta\omega \ll \omega_{Bi}$ from (2) we have

$$\Delta\omega=-\frac{1}{2}(\omega^{(j)}-n\omega_B')\pm\frac{1}{2}\left[(\omega^{(j)}-n\omega_B')^2-4\gamma_m^2\right]^{1/2}, \tag{3}$$

where

$$\gamma_m^2=-\frac{\omega_p'^2}{\omega_B'}\left.\frac{\left[(N^2+\varepsilon_1-\varepsilon_1')b_1-\varepsilon_1b_1'+2\varepsilon_2b_2\right]}{\frac{d}{d\omega}(\varepsilon_1N^2-\varepsilon_1\varepsilon_1'+\varepsilon_2^2)}\right|_{\omega=\omega^{(j)}} \tag{4}$$

An instability occurs for $\gamma_m^2 > 0$ if $|\omega^{(j)} - n\omega'_B| < 2\gamma_m$. The maximum value of the growth rate γ_m is of the same order as (1). For a low-pressure plasma ($\beta \ll 1$), Eq. (4) goes over into the expression obtained in ref. 8 when $k\rho_i \ll 1$.

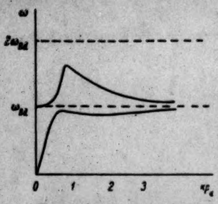

Fig. 1. Frequencies $\omega^{(j)}(k)$ (j = 1, 2) as a function of $k\rho_d$ for a deuterium plasma with β_i = 0.1 in the absence of fast ions.

For a deuterium plasma (i = d), the spectra in the absence of fast ions are shown in Fig. 1 for β = 0.1 (more detailed curves for $\omega^{(j)}(k)$ are shown in ref. 10). In the presence of fast tritium ions, these spectra are changed as shown in Fig. 2.

Using the results of the numerical calculations of ref. 10, one can show that for $\beta \geqslant 1$ an intersection of the branches $\omega = \omega^{(j)}(k)$ and $\omega = \omega_{Bt} = (2/3)\,\omega_{Bd}$ is possible for only the first cyclotron branch of the oscillations of a deuterium plasma ($0 < \omega^{(1)}(k) < \omega_{Bd}$), which corresponds in the longwave limit ($k\rho_i \ll 1$) to a magnetoacoustic wave with frequency $\omega(k) = kv_A$, where $v_A = c\omega_{Bi}/\omega_{pi}$. For $\beta \leq 0.1$, an "interaction" of the cyclotron branch $\omega = n\omega_{Bd}$ occurs for both the first branch $\omega = \omega^{(j)}(k)$ and for the branches with higher numbers $j \geq 2$. For $j \geq 2$, the frequency $\omega^{(j)}(k)$ intersects the frequency $n\omega'_B$ at two values x_0.

6	0.1	1.4	19	0.66
		5.6	85	0.08

In Table 1 we give the results of a calculation of the growth rate for the first six branches excited by fast tritium ions. It is assumed that $v_{Td} = 0.1v_0$. Table 1 contains the calculated values of the coefficient η, which occurs in Eq. (1) for the growth rate, and also the values of the parameter $x_0 = k_0\rho_i$ at which the branches intersect and the corresponding values of A. Similar results for fast He³ ions are shown in Table 2. In this case $\omega'_B = \omega_{BHe^3} = (4/3)\omega_{Bd}$ $v_{Td} = 0.1v_0$. The results given in Tables 1 and 2 confirm the estimate (1) (the value of η varies for the first branches in the range $0.1 \leqslant \eta \leqslant 1$).

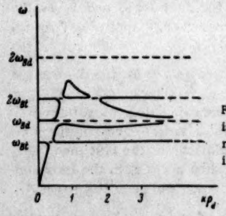

Fig. 2. Dependence of the characteristic frequencies of a deuterium plasma in the presence of a group of fast ions at low density.

Parametric instability of an electron beam in a magnetic field

A. I. Pasynok and N. S. Repalov

Physicotechnical Institute, Academy of Sciences of the Ukrainian SSR, Khar'kov

(Submitted April 13, 1973)
Zh. Tekh. Fiz., 44, 277-283 (February 1974)

A linear theory is developed for the oscillations of an electron beam in a spatially periodic electrostatic field in a presence of a homogeneous magnetic field. In contrast to the case $H_0 \to \infty$, there are additional resonance regions due to the intersection of branches of the dispersion diagram. The conditions under which such resonances occur are studied; expressions are obtained for the maximum growth rates in these resonance regions; the dependence of the growth rate on the period of the modulating field and on the magnitude of the magnetic field are found.

The parametric instability characteristic of an electron beam moving in an external modulating electrostatic field can have important practical applications. The large controllable growth rate[1] and the possibility of frequency tuning and control of the bandwidth[2] make the use of such an arrangement as a microwave amplifier or generator very promising. In the higher resonance regions ($k_0U_0 = n\omega_0$, $n = 3, 4 \ldots$) the interaction between the characteristic oscillations of the beam and the external modulating field leads to effective exchange of energy between the spectral components of the beam oscillations, in which case it is possible to get amplification at a multiplied frequency.[3]

Although the nonlinear theory predicts a suppression of the instability,[4] this occurs at a fairly large amplitude of the electric field of the wave. Therefore, the effect of resonance amplification of space-charge waves of a beam by an external electrostatic field can be used for collective acceleration of charged particles. A high-current electron beam is the basis of a device that is to realize such acceleration. Bearing in mind that the effect of the electric field of the wave approaches the effect of the focusing magnetic field $[(a\omega_0/c) \to \omega_H/\omega_0]$ with increasing beam density, we conclude that the motion of the particles at right angles to the magnetic field can have a significant influence. In addition, the study of the parametric instability in a finite magnetic field is also of interest from another point of view: Under these conditions there exist resonance regimes due to an additional (not present in the case $\omega_H/\omega_0 \to \infty$) branch of characteristic oscillations of the beam. In some cases (for example, when one uses a cold cathode) such resonances are more accessible to experimental investigation than the plasma resonances.[5]

ELECTRIC FIELD IN A MODULATED CYLINDRICAL BEAM

Restricting our study to the linear stage of the instability, we consider the propagation of a weak signal along an electron beam of radius a moving in a perfectly conducting waveguide. The beam is modulated by an electrostatic field $E_M = E_0 \sin k_0 z$ and focused by a homogeneous magnetic field H_0 directed along the axis of the system. The hydrodynamic parameters of the beam in a steady state are given by[2]

$$U_{st} = U_0(1 - \xi\cos k_0 z), \quad n_{st} = n_0(1 + \xi\cos k_0 z),$$

where $\xi = (e\varphi_0)/2mU_0^2$ and φ_0 is the potential of the modulating field. Being interested primarily in slow waves ($U_{ph} \ll c$) and assuming, therefore, that the perturbations are electrostatic, $\mathbf{E} = -\nabla\varphi$, we write the original system of equations in the form

$$\Delta\varphi = -4\pi e n, \quad \frac{\partial n}{\partial t} + \operatorname{div} n\mathbf{U} = 0, \quad m\frac{d\mathbf{U}}{dt} = -e\nabla\varphi + \frac{e}{c}\mathbf{U}\times\mathbf{H}. \tag{1}$$

Since the deviations of all quantities from their values in the steady state are assumed to be small, we linearize the continuity equation and the equation of motion. Then for axisymmetric perturbations ($\partial/(\partial\varphi) = 0$) that depend on the time as $e^{i\omega t}$, we obtain

$$\begin{gathered} i\omega n_1 + n_{st}(z)\left(\frac{\partial U_{1r}}{\partial r} + \frac{U_{1r}}{r} + \frac{\partial U_{1z}}{\partial z}\right) + U_{st}(z)\frac{\partial n_1}{\partial z} \\ -(n_1U_0 - n_0U_1)\frac{\partial U_{st}(z)}{\partial z} = 0, \\ i\omega U_{1r} + U_{st}(z)\frac{\partial U_{1r}}{\partial z} = -\frac{e}{m}\frac{\partial\varphi_1}{\partial r} + \omega_H U_{1\varphi}, \\ i\omega U_{1\varphi} + U_{st}(z)\frac{\partial U_{1\varphi}}{\partial z} = -\omega_H U_{1r}, \\ i\omega U_{1z} + U_{st}(z)\frac{\partial U_{1z}}{\partial z} + \xi k_0 U_0 U_{1z}\sin k_0 z = -\frac{e}{m}\frac{\partial\varphi_1}{\partial z}, \end{gathered} \tag{2}$$

where the subscript 1 is appended to the deviations of the corresponding quantities from their values in the steady state.

Making a Fourier transformation with respect to the z coordinate in the original system of equations, we find that the Poisson equation becomes

$$\frac{1}{r}\frac{\partial}{\partial r}r\frac{\partial}{\partial r}\varphi(k, r) - k^2\varphi(k, r) = -4\pi e\mathbf{n}(k, r), \tag{3}$$

and the equation of motion and the continuity equation form an infinite chain of algebraic equations that can be written symbolically as

$$\left.\begin{gathered} n\left(\frac{1}{r} + \frac{\partial}{\partial r}\right)\hat{D}\mathbf{U}_r + \hat{M}\mathbf{n} - n_0\hat{N}\mathbf{U}_z = 0, \\ \hat{K}\mathbf{U}_r = -\frac{e}{m}\frac{\partial\varphi}{\partial r} + \omega_H\mathbf{U}_\varphi, \\ \hat{K}\mathbf{U}_\varphi = -\omega_H\mathbf{U}_r, \\ \hat{M}\mathbf{U}_z = \frac{e}{m}\hat{L}\varphi. \end{gathered}\right\} \tag{4}$$

Here, $\mathbf{U}_\alpha$, $\mathbf{n}$, and φ are column vectors of infinite dimension in the wave-number space ($k \pm mk_0$, $m = 0, 1, 2 \ldots$) and the subscript 1 has been omitted. The elements of the matrices $\hat{D}$, $\hat{M}$, $\hat{N}$, $\hat{K}$, and $\hat{L}$ are

$$\left.\begin{gathered} D_{mn} = \frac{\xi}{2}\delta_{m-1n} + \delta_{mn} + \frac{\xi}{2}\delta_{m+1n}, \\ M_{mn} = \lambda_m\delta_{m-1n} + \gamma_m\delta_{mn} + \lambda_m\delta_{m+1n}, \\ N_{mn} = \frac{\lambda_m}{U_0}\delta_{m-1n} + ik_m\delta_{mn} + \frac{\lambda_m}{U_0}\delta_{m+1n}, \\ K_{mn} = \lambda_{m-1}\delta_{m-1n} + \gamma_m\delta_{mn} + \lambda_{m+1}\delta_{m+1n}, \\ L_{mn} = ik_m\delta_{mn}, \end{gathered}\right\} \tag{5}$$

where $\gamma_m = i(\omega - (k \pm mk_0)U_0)$; $\lambda_m = i(\xi/2)(k \pm mk_0)U_0$;

$k_m = k \pm mk_0$. Multiplying the last three equations in (4) by the corresponding inverse matrices, we find the vectors

$$\begin{gathered} \mathbf{U}_r = -\frac{e}{m}\hat{K}^{-1}\frac{\partial\varphi}{\partial r} + \omega_H\hat{K}^{-1}\mathbf{U}_\varphi, \\ \mathbf{U}_\varphi = -\omega_H\hat{K}^{-1}\mathbf{U}_r, \\ \mathbf{U}_z = \frac{e}{m}\hat{M}^{-1}\hat{L}\varphi. \end{gathered} \tag{6}$$

The relations in (6) together with the first equation of (4) can be used to express the perturbation of the beam density in terms of the wave potential:

$$\mathbf{n} = \frac{e}{m}n_0\left[\hat{M}^{-1}\hat{N}\hat{M}^{-1}\hat{L} + \frac{1}{r}\frac{\partial}{\partial r}\left(r\frac{\partial}{\partial r}\right)\hat{M}^{-1}\hat{D}\hat{F}^{-1}\hat{K}^{-1}\right]\varphi, \tag{7}$$

where $\hat{F} = \hat{e} + \omega_H^2(\hat{K}^{-1})^2$ and $\hat{e}$ is the identity matrix in the k space.

Substitution of $\mathbf{n}$ from (7) into Eq. (3) leads to the final equation, which describes the propagation of a weak signal along an electron beam focused by a homogeneous longitudinal magnetic field of arbitrary magnitude:

$$\frac{1}{r}\frac{\partial}{\partial r}\left(r\frac{\partial}{\partial r}\right)\varphi - k^2\varphi = -\omega_0^2\hat{Q}\varphi, \tag{8}$$

where $\hat{Q}$ is the linear operator in the square brackets of Eq. (7).

The inverse matrices in $\hat{Q}$ can be represented as series in powers of ξ. One can show that if all the diagonal elements of the inverse matrices obtained in this manner are nonvanishing then the series converges uniformly. In the expansion of the inverse matrices we now omit all terms except the diagonal terms and terms linear in ξ; then Eq. (8) becomes

$$\begin{aligned} &\varepsilon_1\frac{1}{r}\frac{\partial}{\partial r}r\frac{\partial\varphi(k, r)}{\partial r} - k^2\varepsilon_3\varphi(k, r) \\ &= \frac{\xi}{2}\left(a_{-1} + b_{-1}\frac{1}{r}\frac{\partial}{\partial r}r\frac{\partial}{\partial r}\right)\varphi(k - k_0, r) \\ &+ \frac{\xi}{2}\left(a_{+1} + b_{+1}\frac{1}{r}\frac{\partial}{\partial r}r\frac{\partial}{\partial r}\right)\varphi(k + k_0, r), \end{aligned} \tag{9}$$

where a_{-1} and a_{+1} are defined by

$$a_{-1} = \frac{k(k - k_0)\,\omega_0^2\varkappa(k, k - k_0)}{(\omega - kU_0)[\omega - (k - k_0)U_0]}, \quad a_{+1} = \frac{k(k + k_0)\,\omega_0^2\varkappa(k, k + k_0)}{(\omega - kU_0)[\omega - (k + k_0)U_0]}, \tag{10}$$

and ε_1 and ε_3 are the corresponding components of the permittivity tensor of the beam in the hydrodynamic approximation:

$$\varepsilon_1(k, \omega) = 1 - \frac{\omega_0^2}{(\omega - kU_0)^2 - \omega_H^2}, \quad \varepsilon_3(k, \omega) = 1 - \frac{\omega_0^2}{(\omega - kU_0)^2}, \tag{11}$$

and the coefficients b_{-1} and b_{+1} are given by

$$\begin{aligned} b_{\pm1} = 1 - \varepsilon_1(k, \omega) - \frac{(k \pm k_0)U_0}{\omega - kU_0} \\ \times (1 - \varepsilon_1(k \pm k_0, \omega))\left[1 + \frac{\omega_H^2}{\omega_0^2}(1 - \varepsilon_1(k, \omega))\right] \\ - \frac{(k \pm k_0)U_0}{\omega - (k \pm k_0)U_0}(1 - \varepsilon_1(k, \omega))\left[1 + \frac{\omega_H^2}{\omega_0^2}(1 - \varepsilon_1(k \pm k_0, \omega))\right]. \end{aligned} \tag{12}$$

RESONANCE CONDITIONS AND FIELDS IN AN ELECTRON BEAM THAT COMPLETELY FILLS A WAVEGUIDE

If the beam completely fills the cross section of a waveguide, we can write the solution of the chain of equations which is finite at the axis and vanishes at the conducting walls ($r = a$) in the form

$$\varphi(k, r) = \sum_n A_n(k)\,J_0\left(\sigma_n\frac{r}{a}\right). \tag{13}$$

We restrict ourselves to studying interactions in which only three waves – two characteristic waves and a modulating wave – participate.[2] When the solution (13) is substituted into the system (9) we assume that only the coefficients A_k and A_{k+k_0} are nonvanishing. We obtain a system of algebraic equations for these coefficients for the lowest mode ($n = 1$):

$$\left.\begin{aligned} D_k(\omega)A_k + \frac{\xi}{2}\left(a_{+1}(k) - \frac{\sigma_{01}^2}{a^2}b_{+1}(k)\right)A_{k+k_0} = 0, \\ \frac{\xi}{2}\left(a_{-1}(k + k_0) - \frac{\sigma_{01}^2}{a^2}b_{-1}(k + k_0)\right)A_k + D_{k+k_0}(\omega)A_{k+k_0} = 0, \end{aligned}\right\} \tag{14}$$

where $D_k(\omega) = (\sigma_{01}^2/a^2)\varepsilon_1(k, \omega) + k^2\varepsilon_3(k, \omega)$.

Equating the determinant of (14) to zero we find the dispersion relation

$$\begin{aligned} D_k(\omega)D_{k+k_0}(\omega) = \frac{\xi^2}{4}\left[a_{+1}(k) - \frac{\sigma_{01}^2}{a^2}b_{+1}(k)\right] \\ \times\left[a_{-1}(k + k_0) - \frac{\sigma_{01}^2}{a^2}b_{-1}(k + k_0)\right]. \end{aligned} \tag{15}$$

To terms of order ξ, the amplitudes of the spectral components of the field are, from (14),

$$A_k = \frac{1}{D_k(\omega)}, \quad A_{k+k_0} = \frac{\xi}{2}\,\frac{a_{-1}(k + k_0) - \frac{\sigma_{01}^2}{a^2}b_{-1}(k + k_0)}{D_k(\omega)\,D_{k+k_0}(\omega)}. \tag{16}$$

Since ξ is small, A_k and A_{k+k_0} can be commensurable only under resonance conditions, for which $D_k(\omega)$ and $D_{k+k_0}(\omega)$ vanish simultaneously. In this case, the solutions of the dispersion relation $\omega(k)$ become complex, and a state with constant wave amplitude becomes unstable. The maximum growth rate at exact resonance can be found by analogy with ref. 2;

$$\gamma_{\max} = \frac{\xi}{2}\,\frac{\left[a_{+1}(k) - \frac{\sigma_{01}^2}{a^2}b_{+1}(k)\right]^{1/2}\left[a_{-1}(k + k_0) - \frac{\sigma_{01}^2}{a^2}b_{-1}(k + k_0)\right]^{1/2}}{[D'_\omega(k, \omega)\,D'_\omega(k + k_0, \omega)]^{1/2}}. \tag{17}$$

Calculations show that the numerator of (17) is always positive at resonance; therefore there the instability arises only when the frequency derivatives of $D_k(\omega)$ and $D_{k+k_0}(\omega)$ have opposite signs. The physical meaning of this condition can be elucidated on the basis of the following arguments: The internal energy of the electromagnetic field of waves with wave-vector projections onto the z axis equal to k and $k + k_0$ is

$$W_k \sim \frac{A_k^2}{8\pi}\frac{\partial}{\partial\omega}(\omega D_k(\omega)), \quad W_{k+k_0} \sim \frac{A_{k+k_0}^2}{8\pi}\frac{\partial}{\partial\omega}(\omega D_{k+k_0}(\omega)). \tag{18}$$

Suppose that the beam–field system is conservative, i.e., we have broken the energy channel linking the waves to the external source which is realized through the modulating wave. It is obvious that all changes in such a system preserve both the energy and the wave number. Comparison of these conditions shows[6-8] the system is unstable if one of the excited waves is a negative-energy wave ($\omega D'_\omega(k, \omega) < 0$). This is the case when

$$D'_\omega(k, \omega) D'_\omega(k+k_0, \omega) < 0. \tag{19}$$

To establish the conditions under which there is parametric instability in the beam, i.e., the inequality (19) is satisfied, we find the solution of Eq. (15) as $\xi \to 0$. Setting $D_k(\omega) = 0$, we find

$$\omega'^2_{1,2} = \frac{1}{2}(\omega_0^2 + \omega_H^2) \pm \frac{1}{2}\sqrt{(\omega_0^2 + \omega_H^2)^2 - 4\omega_0^2\omega_H^2 \frac{k^2}{k^2 + \frac{\sigma_{01}^2}{a^2}}}. \tag{20}$$

The condition $D_{k+k_0}(\omega) = 0$ leads to the similar dependence

$$\omega''^2_{1,2} = \frac{1}{2}(\omega_0^2 + \omega_H^2) \pm \frac{1}{2}\sqrt{(\omega_0^2 + \omega_H^2)^2 - 4\omega_0^2\omega_H^2 \frac{(k+k_0)^2}{(k+k_0)^2 + \frac{\sigma_{01}^2}{a^2}}}. \tag{21}$$

Using the relation $\tan\theta = (k_\perp/k) = (\sigma_{01}/ak)$, we see that Eqs. (20) and (21) describe the dispersion of longitudinal waves propagating in a cold electron plasma at an angle θ to the magnetic field. It is not difficult to show that there are three types of resonance conditions that lead to a parametric instability. Let us first consider the case of a strong magnetic field ($\omega_H > \omega_0$). In this case, there is a plasma–plasma resonance if the branches of the dispersion diagram that tend asymptotically to ω_0 as $k \to \infty$ intersect. The resonance region is determined by the inequality

$$\omega_0 < k_0 U_0 \leqslant 2\omega_0. \tag{22}$$

If $k_0 U_0$ is greater than twice the plasma frequency, the dispersion curves cannot intersect, and there is no resonance. But if $k_0 U_0$ approaches ω_0, the system enters the region of basic resonance; although this is stronger than the parametric resonance, it leads to a stationary modulation of the beam, i.e., one in which the potential of the perturbation grows in space but does not depend on the time. The plasma–plasma resonance with broadest band occurs when $k_0 U_0 \simeq 2\omega_0$. In this case, there is amplification in the frequency band:

$$\frac{1}{O\left(\frac{U_T^2}{U_0^2}\right)} > \omega > \omega_{\min}(\xi). \tag{23}$$

The instability band is bounded from above in frequency by the thermal motion of the beam particles[1] and from below by the amplitude of the modulating field. The maximum growth rate in this region is

$$\gamma_{\max} = \frac{3}{4}\xi\omega_0 = \frac{1}{2}\frac{ek_0\varphi_0}{mU_0}. \tag{24}$$

Cyclotron–cyclotron resonance occurs when the cyclotron branches of the dispersion diagram intersect. This resonance occurs when

$$\omega_H + (\omega_0^2 + \omega_H^2)^{1/2} > k_0 U_0 \geqslant 2\omega_H \tag{25}$$

and is the one with the broadest band near the lower boundary. The region of frequencies in which there is signal amplification because of cyclotron–cyclotron resonance is also determined by an inequality like (23). It should be pointed out that the calculation of the growth rate near the lower boundary of the resonance on the basis of Eq. (17) is incorrect because the basic assumption in the derivation of Eq. (9) – that the diagonal elements of the matrices $\hat{F}^{-1}$ and $\hat{K}^{-1}$ vanish – no longer holds, and the procedure for expanding the inverse matrices in powers of ξ leads to divergent series for $k \gg k_\perp$.

The third kind of instability that occurs in an electron beam with a finite focusing magnetic field is due to a cyclotron–plasma resonance; this occurs when

$$\omega_0 + (\omega_0^2 + \omega_H^2)^{1/2} > k_0 U_0 > \omega_H. \tag{26}$$

An instability occurs in the frequency interval (23) when

$$k_0 U_0 \to \omega_H + \omega_0. \tag{27}$$

The maximum growth rate can be calculated, and is

$$\gamma = \frac{3}{4}\omega_0 \frac{\sigma U_0}{\sqrt{\omega_0^2 + \omega_H^2}}. \tag{28}$$

In weak magnetic fields ($\omega_H < \omega_0$), the region of the plasma–plasma resonance is determined by (25), of the cyclotron–cyclotron resonance by (22), and of the cyclotron–plasma resonance by (26). In this case, the maximum growth rate for the cyclotron resonance is

$$\gamma = \frac{3}{4}\omega_H \frac{\sigma U_0}{\sqrt{\omega_0^2 + \omega_H^2}}. \tag{29}$$

DISPERSION PROPERTIES OF A MODULATED ELECTRON BEAM

We investigate the dispersion properties of a modulated electron beam in a homogeneous magnetic field. To do this, assuming $\xi \neq 0$ we solve Eq. (15) in the neighborhood of each of the above resonances, i.e., near the point of intersection of the corresponding dispersion curves. A typical dependence of the signal frequency on the projection of the wave vector on the z axis is shown in Fig. 1. In the frequency interval $\omega_{\min} < \omega < \omega_{\max}$ the solution of the dispersion relation $\omega(k)$ becomes complex, i.e., the beam is unstable against the excitation of waves in the given frequency interval. The width of the instability region $\omega_{\max} - \omega_{\min}$ for fixed ω_H/ω_0 and g_0 is proportional to ξ, the modulation depth of the beam. The maximum growth rate for any resonance condition depends on both the magnitude of the magnetic field and the period of the modulating field $r\lambda/k_0$. In particular, for the plasma–cyclotron resonance, $\gamma_{\max}$ is shown as a function of g_0 in Fig. 2. It can be seen from Fig. 2 that $\gamma_{\max}$ reaches its greatest value near the upper boundary (26). If g_0 increases further, the growth rate decreases rapidly and at $g_0 = g_{0\max}$ the beam becomes stable. An increase of the focusing field decreases the growth rate of the cyclotron–

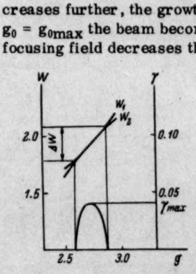

Fig. 1. Dependence of the signal frequency on the projection of the wave vector onto the z axis under resonance conditions [$W = \omega/\omega_0$, $g = (k_z U_0)/\omega_0$].

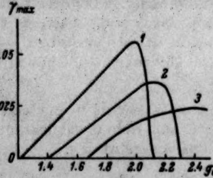

Fig. 2. Maximum growth rate as a function of the period of the modulating field. H: 1) 1.0; 2) 1.25; 3) 1.5; $H = \omega_H/\omega_0$.

plasma instability on the one hand, and displaces the upper boundary of the resonance to larger g_0. In the case of plasma–plasma resonance, an increase in H_0 is accompanied by an increase in γ_{max}, which tends to its limiting value (24).

A large series of calculations made for different values of g_0 enables us to determine the instability region for these resonances (at a constant magnetic field). In Fig. 3 we show the boundaries of these regions and the region corresponding to stable solutions of the dispersion relation (15). It can be seen that the width of the amplification band varies with the period of the modulating field: As long as $g_0 < g_{0,\mathrm{lim}}$, which corresponds to the upper boundary of the instability, a narrow band of frequencies can be amplified in the beam with growth rate $\gamma < \gamma_{\mathrm{lim}}$, and with increasing g_0 the range of amplified frequencies becomes larger and amplification can occur with growth rate of the order of γ_{lim}.

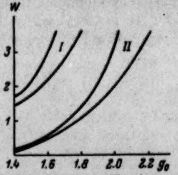

Fig. 3. Regions of instability of a modulated beam under the conditions for the existence of plasma–plasma (I) and plasma–cyclotron (II) resonance (H_0 = const).

Scattering by ion-acoustic waves in a rectangular waveguide

S. V. Troitskii

A. M. Gor'kii Khar'kov State University

(Submitted April 19, 1973)
Zh. Tekh. Fiz., 44, 284-290 (February 1974)

An analytical expression is obtained for the scattering cross section for the fundamental mode in a rectangular waveguide containing a plasma in which there is a directed drift of the electrons with respect to the ions. Using linear theory, we study scattering conditions close to threshold, where the fluctuation level in the plasma is anomalously large. An experiment is described which involves scattering by ion-acoustic oscillations in a helium positive column located in a rectangular waveguide.

INTRODUCTION

Incoherent scattering of electromagnetic waves is one of the most reliable of present-day methods for noncontact plasma diagnostics. It has found extensive application both in studies of the upper ionized layers of the atmosphere and in laboratory plasma diagnostics (for example, by means of lasers).

In both cases, however, it is usually assumed that the wavelength of the probing signal is considerably smaller than the dimensions of the plasma; this assumption allows us to neglect boundary effects and serves as the basis for a comparison of experimental results with the theory for incoherent scattering of waves in an unbounded plasma.

However, there is considerable interest in the case in which the wavelength of the probing signal, λ_0, is comparable with the dimension l of the plasma. Successful realization of the incoherent scattering method in this case demands a theory which describes incoherent scattering in bounded plasma volumes; a comparison of experimental and theoretical data when $\lambda_0 \sim l$ is possible only with a systematic consideration of boundary effects.

Some of the first results of an analytic study of incoherent scattering in a bounded plasma appear in refs. 1-3. The present paper describes an experiment on scattering of microwaves by fluctuations in the plasma of the positive column of a glow discharge in a rectangular waveguide. Earlier results[2,3] are generalized to the case of a nonequilibrium plasma with a directed drift of electrons with respect to ions in order to compare the experimental data with theory.

EFFECT OF DIRECTED ELECTRON DRIFT ON SCATTERING IN A WAVEGUIDE

We consider a rectangular waveguide completely filled by a homogeneous electron–ion plasma that is not in equilibrium. The dielectric tensor of the plasma (including electron drift with a velocity u with respect to stationary ions) is determined in the nonrelativistic case $u \ll c$ (neglecting spatial dispersion) by the following expression:[4]

$$\varepsilon_{ij}(\omega, \mathbf{k}) = \varepsilon(\omega)\delta_{ij} - \frac{\omega_p^2}{\omega'^2}\left[\frac{\omega'}{\omega^2}(k_i u_j + u_i k_j) + k^2\frac{u_i u_j}{\omega^2}\right], \tag{1}$$

where

$$\left.\begin{aligned} \varepsilon(\omega) = 1 - \frac{\omega_p^2}{\omega^2} - \frac{\omega_{pi}^2}{\omega^2}, \quad \omega' = \omega - \mathbf{ku}, \\ \omega_p^2 = \frac{4\pi e^2 N}{m_e}, \quad \omega_{pi}^2 = \frac{4\pi e^2 N}{m_i}, \end{aligned}\right\} \tag{2}$$

e and m_e are the charge and mass of the electron, m_i is the mass of the ion, and N is the equilibrium plasma density.

A plasma with the tensor (1) is not isotropic for any direction of the velocity **u**. However, it is evident that the deviation from isotropy in (1) in the nonrelativistic case $u \ll c$ for fast waves with a phase velocity $v_p > c$ is determined by small terms of order

$$\frac{ku}{\omega} \ll 1. \tag{3}$$

Therefore when (3) is satisfied, it is inexpedient to solve the problem of wave propagation in a waveguide filled by a medium with the tensor (1); neglecting the small terms in (1), we describe the plasma in the waveguide by the dielectric constant

$$\varepsilon_{ij}(\omega) = \delta_{ij}\varepsilon(\omega).$$

We point out that despite the possibility of neglecting the quite small effect of drift velocity on wave propagation (in analogy to the neglect of the effect of spatial dispersion on electromagnetic wave propagation), consideration of drift velocity, like consideration of spatial dispersion, is necessary in principle for the calculation of the correlation functions which determine the incoherent scattering cross sections; in the linear theory it is precisely this consideration which determines the structure of the scattering cross section and the effectiveness of wave scattering by plasma fluctuations.[5]

Thus the inequality (3) gives a condition for which the problem of scattering in a waveguide containing a nonequilibrium plasma can be solved as before[2,3] and the analytic expressions for the scattering cross section in the case of equilibrium (**u** = 0) and nonequilibrium (**u** ≠ 0) plasmas agree formally, with the one difference that in the latter case (**u** ≠ 0) the correlation function for the electron density must be calculated with the electron drift included.

Limiting the discussion to scattering of the fundamental mode (with frequency ω_0) and excitation of the H_{m0} mode (with frequency ω), and following ref. 2, we write the differential scattering cross section as

$$\frac{d\sigma^{\alpha}_{H_{10}\to H_{m0}}}{d\omega} = \frac{\dfrac{16\pi^5 r_e^2\omega}{\omega_0}}{ab\,|k_z|\,k_{z0}}\left\{\langle\delta n^2\rangle_{q_-^{\alpha}\Delta\omega}(1+\delta_{m1}) + \langle\delta n^2\rangle_{q_+^{\alpha}\Delta\omega}\right\}. \tag{4}$$

In contrast to ref. 2, we shall understand by the quantities $\langle\delta n^2\rangle_{q_\pm^{\alpha}\Delta\omega}$ the spectral distributions of the correlation functions for electron density calculated with electron drift included. For a nonequilibrium (but stable) plasma, the assumptions made earlier[1-3] regarding the smallness of the correlation radius in comparison with the scattering plasma volume remain valid and we use the expression for the electron density correlation function in an unbounded plasma:[5,6]

$$\langle \delta n^2 \rangle_{q\Delta\omega} = \frac{2q^2}{(2\pi)^4 e^2 |\varepsilon_l|^2}$$
$$\times \left\{ |1 + 4\pi\varkappa_l^i|^2 \frac{T_e}{\Delta\omega - \mathbf{qu}}\, \mathrm{Im}\, \varkappa_l' + |4\pi\varkappa_l'|^2 \frac{T_i}{\Delta\omega}\, \mathrm{Im}\, \varkappa_l^i \right\}, \tag{5}$$

where

$$\left.\begin{aligned} &\varepsilon_l = 1 + 4\pi(\varkappa_l' + \varkappa_l^i),\\ &\varkappa_l' = \frac{1}{4\pi r_d^2 q^2}\left\{1 - \varphi(z') + i\sqrt{\pi}\, z' e^{-z'^2}\right\},\\ &\varkappa_l^i = \frac{t}{4\pi r_d^2 q^2}\left\{1 - \varphi(z_i) + i\sqrt{\pi}\, z_i e^{-z_i^2}\right\},\\ &z' = \sqrt{\frac{m_e}{2T_e}}\,\frac{(\Delta\omega - \mathbf{qu})}{q}, \quad z_i = \sqrt{\frac{m_i}{2T_i}}\,\frac{\Delta\omega}{q}, \quad \Delta\omega = \omega - \omega_0,\\ &t = \frac{T_e}{T_i}, \quad r_d^2 = \frac{T_e}{4\pi e^2 N}, \quad \varphi(z) = 2ze^{-z^2}\int_0^z e^{x^2}dx. \end{aligned}\right\} \tag{6}$$

Here, T_e and T_i are respectively the electron and ion temperatures in energy units, and the index α takes on the values (±) with $\alpha = (+)$ corresponding to forward scattering and $\alpha = (-)$ to backscattering.

With substitution of (6) in Eqs. (4) and (5), the quantity q for the change in the wave vector during scattering in the waveguide takes on a discrete set of values as a function of the number m which arises because of the wave scattering $\mathbf{q} \to \mathbf{q}_\pm^\alpha$,

$$\left.\begin{aligned} &\mathbf{q}_\pm^\alpha = \mathbf{e}_x \frac{(m \pm 1)\pi}{a} + \mathbf{e}_z q_z^\alpha, \quad q_z^\alpha = \alpha k_z - k_{z0},\\ &k_{z0} = \sqrt{\frac{\omega_0^2}{c^2}\varepsilon(\omega_0) - \frac{\pi^2}{a^2}}, \quad k_z = \sqrt{\frac{\omega^2}{c^2}\varepsilon(\omega) - \left(\frac{m\pi}{a}\right)^2}, \end{aligned}\right\} \tag{7}$$

a and b are the transverse dimensions of the waveguide; $\mathbf{e}_x$ and $\mathbf{e}_z$ are unit vectors along the corresponding axes.

For small frequency variations, $q\sqrt{T_e/m_e} \ll \Delta\omega \ll q\sqrt{T_i/m_i}$, $z' \ll 1$, $z_i \gg 1$, the correlation function (5) can be written

$$\langle \delta n^2 \rangle_{q\Delta\omega} = \sqrt{\frac{\pi}{8M}}\,\frac{\pi N R(q)\, q V_s}{(2\pi)^4 (1 + r_d^2 q^2)^3}\,\frac{\delta(\Delta\omega - \omega_s) + \delta(\Delta\omega + \omega_s)}{|\gamma(\mathbf{q}, \Delta\omega)|}, \tag{8}$$

where

$$\left.\begin{aligned} &\gamma(\mathbf{q}, \Delta\omega) = \sqrt{\frac{\pi}{8M}}\left[\frac{qV_s}{(1 + r_d^2 q^2)^2}\left(1 + \sqrt{Mt^3}\, e^{-\frac{t/2}{1 + r_d^2 q^2}}\right) - \frac{\frac{\Delta\omega \mathbf{qu}}{qV_s}}{1 + r_d^2 q^2}\right],\\ &R(q) = 1 + \frac{\pi t^3}{2(1 + r_d^2 q^2)}\, e^{-\frac{t}{1 + r_d^2 q^2}} + \sqrt{Mt}\, e^{-\frac{t/2}{1 + r_d^2 q^2}},\\ &M = \frac{m_i}{m_e}, \quad V_s^2 = \frac{T_e}{m_i}, \quad \omega_s = \frac{qV_s}{\sqrt{1 + r_d^2 q^2}}. \end{aligned}\right\} \tag{9}$$

Equating the damping $\gamma(\mathbf{q}, \Delta\omega)$ to zero[5] we can determine the boundary between damped and growing ion-acoustic oscillations with frequencies $\pm\omega_s$. The fact that the correlation functions approach infinity when $\gamma(\mathbf{q}, \Delta\omega) \to 0$ is analogous to the anomalously high level of fluctuation in matter near the liquid–gas phase transition, and within the limits of linear theory Eqs. (4) and (8) describe a significant increase in the scattering cross section for electromagnetic waves in a rectangular waveguide filled with a plasma when $\gamma(\mathbf{q}, \Delta\omega) \to 0$, which corresponds to the well-known phenomenon of critical opalescence.

Let the drift velocity be $\mathbf{u} \parallel Oz$, i.e., coincide with the direction of propagation of an incident wave in the waveguide. In this case, the expressions for the forward-scattering cross sections agree with the corresponding expressions in the case of a waveguide containing an equilibrium plasma[2] since for small changes in frequency $\Delta\omega$, $q_z^+ \approx 0$ and $\mathbf{q}^+\mathbf{u} = q_z^+ u \approx 0$. We shall therefore only consider back-scattering in the following and omit the index α everywhere.

For back-scattering, the product $\mathbf{q}_\pm \mathbf{u}$ is always negative and $\gamma(\mathbf{q}, \Delta\omega)$ can go to zero only when $\Delta\omega = -\omega_s$. For $\Delta\omega = \omega_s$, $\gamma(\mathbf{q}, \omega_s)$ does not go to zero, the ion-acoustic oscillations experience strong damping, and the scattering cross section is smaller than for $\Delta\omega = -\omega_s$.

In the following, we limit ourselves to $H_{10} \to H_{10}$ scattering (m = 1). For practical purposes, the integrated scattering cross sections, which are

$$\sigma = \int_{-\infty}^{\infty} \frac{d\sigma_{H_{10} \to H_{10}}}{d\omega}\, d\omega.$$

are of interest.

Substituting Eq. (8) into Eq. (4), we obtain the results of integration of the scattering cross section with the help of $\delta(\Delta\omega - \omega_s)(\sigma_+)$ or of $\delta(\Delta\omega + \omega_s)(\sigma_-)$ in the form

$$\sigma_\pm = \frac{\pi^3 N r_e^2 V_s}{ab\omega_0 k_{z0}}\sqrt{\frac{\pi}{8M}}\,\{2f^\pm(q_-) + f^\pm(q_+)\}, \tag{10}$$

where

$$\left.\begin{aligned} &f^\pm(q) = \frac{q\omega^\pm R(q)}{(1 + r_d^2 q^2)^3\, |k_z^\pm \gamma^\pm(q)|},\\ &\omega^\pm = \omega_0 \pm \omega_s, \quad k_z^\pm = k_z(\omega^\pm), \quad \gamma^\pm(q) = \gamma(q, \pm\omega_s). \end{aligned}\right\} \tag{11}$$

In order to study the scattering cross section σ_- near the critical mode ($\gamma^-(q) = 0$) for negative detuning, we write $\gamma^-(q)$ in the long-wave region $r_d^2 q^2 \ll 1$ as a series in powers of $r_d^2 q^2$

$$\gamma^-(q) = q\sqrt{\frac{\pi}{8M}}\left\{\left(V_0 - \frac{|q_z|u}{q}\right)\right.$$
$$\left. - r_d^2 q^2\left[2V_0 - \frac{V_s}{2}\sqrt{Mt^3}\, e^{-t/2} - \frac{3}{2}\,\frac{|q_z|u}{q}\right] + \ldots\right\}, \tag{12}$$

where

$$V_0 = V_s(1 + \sqrt{Mt^3}\, e^{-t/2}). \tag{13}$$

In particular, since $|q_{z-}| = q_-$, we consider the case $u = V_0$. In this case, for $\Delta\omega = -\omega_s$ the damping constant can be represented as

$$\gamma^-(q_-) \cong \sqrt{\frac{\pi}{8M}}\, r_d^2 q_-^3 V_1, \tag{14}$$

where

$$V_1 = \frac{V_s}{2}\left[\sqrt{Mt^3}\,(t - 1)\, e^{-t/2} - 1\right]. \tag{15}$$

Since only nongrowing ion-acoustic oscillations are considered in the scattering, $\gamma^{-}(q_{-})$ must be positive and the condition $\gamma^{-}(q_{-}) = 0$ (or $V_1 = 0$) gives a critical ratio t_c for the temperatures, which can be determined from (see ref. 7 also)

$$t_c^{3/2}e^{-t_c/2}(t_c-1)=\frac{1}{\sqrt{M}}. \qquad (16)$$

When $u = V_0$ and $r_d^2q^2 \ll 1$, from Eq. (12) we have

$$\gamma^{-}(q_{+})\cong\sqrt{\frac{\pi}{8M}}\,q_{+}V_0\left(1-\frac{|q_{r+}|}{q_{+}}\right). \qquad (17)$$

In the region of ion sound

$$\frac{1}{r_d^2q^2}=\frac{\omega_{pi}^2}{\omega_s^2}-1,$$

and taking account of Eqs. (14), (17), and (11), when $t_c \gtrsim t \gg 1$ and $R(q) \cong 1$ we obtain from Eq. (10)

$$\sigma_{-}\cong\frac{\pi^2Nr_e^2}{ab\omega_0k_{z0}}\left\{2\,\frac{V_s}{V_1}\,\frac{\omega_{-}^{-}}{|k_z(\omega_{-}^{-})|}\left(\frac{\omega_{pi}^2}{\omega_s^2}-1\right)+\frac{V_s}{V_0}\,\frac{\omega_{+}^{-}}{|k_z(\omega_{+}^{-})|\left(1-\frac{|q_{r+}|}{q_{+}}\right)}\right\}, \qquad (18)$$

where $\omega_{\pm}^{-} = \omega^{-}(q_{\pm})$.

For small $\Delta\omega \ll \omega_0$, one can make the approximation $\omega_{\pm}^{-} \approx \omega_0$, $|k_z(\omega_{\pm}^{-})| \approx k_{z0}$, so that

$$\sigma_{-}\cong\frac{\pi^2Nr_e^2}{abk_{z0}^2}\left\{2\,\frac{V_s}{V_1}\left(\frac{\omega_{pi}^2}{\omega_s^2}-1\right)+\frac{V_s}{V_0\left(1-\frac{|q_r|}{q_{+}}\right)}\right\}. \qquad (19)$$

EXPERIMENT AND DISCUSSION OF RESULTS

The device shown in Fig. 1 is used for the experimental study of incoherent scattering in a waveguide. A study has been made of back-scattering of the fundamental wave in a standard rectangular waveguide for the three-centimeter range (cross section 10 × 23 mm). The helium plasma in the positive column of a glow discharge with gas pressures of 0.06-10 mm Hg and discharge currents of 2-150 mA is located in the waveguide. By means of a ferrite Y coupler (see Fig. 1), the reflected signal (including that scattered by plasma fluctuations) of the fundamental H_{10} mode is directed to a P5-10 high-sensitivity superheterodyne receiver with a threshold sensitivity of $7\cdot10^{-17}$ W. At the receiver input there is a resonator with a 10 MHz passband which is tuned to the frequency of the device and which blanks out the scale signal at the receiver. Power measurements are made in a narrow passband of the receiver having a width of 1 MHz at 50% power level.

Power scattered by fluctuations for a given detuning from the central frequency f_0 of the oscillator is determined from the difference between the total power measured by the receiver during probing of the plasma and the sum of the intrinsic radiation of the plasma and the power reaching the receiver with no plasma present in the waveguide. The power meter PM provides an indication of the level of continuous power from the probing-signal generator. This same arrangement (Fig. 1) without the oscillator can also be used for studies of intrinsic plasma radiation. In comparison with the experimental scattering arrangement used in ref. 8 and also in comparison with experiments on the scattering of laser light where the scattered energy is distributed in all directions and only an insignificant portion of the scattered signal reaches the receiver, the scattered energy is propagated in only two directions in this waveguide scheme: forward and backward, with the back-scattering cross section greater than the cross section for forward scattering as shown by calculation (see, for example, ref. 2).

Introduction of the glass vessel PV into the waveguide is accomplished by means of the separable sections SC, which are cut into two halves so that the lines of high-frequency conductivity currents do not pass through the plane of the cut. To reduce reflections, the vessel is closed off with half-wave conical transition sections. The thin-walled glass vessel, rectangular in cross section and 70-110 mm long, is fabricated by means of a special massive rectangular bronze mold which is heated to 500°C by heating elements during molding and which produces a vessel with external dimensions of 9.8 × 22.8 mm. The wire anode of the vessel is within the waveguide and along its axis, and the cylindrical cold cathode is removed from the waveguide by means of a tube 9 mm in diameter; this ensures insignificant perturbation of the wave field by the electrodes of the discharge vessel.

Measurements are made of integrated back-scattering cross sections multiplied by the magnitude of the entire plasma volume in the waveguide. Measurements are made for various detuning values $\Delta f = f - f_0$ from the central frequency of the oscillator spectrum starting with Δf ± 10 MHz.

Waveguide methods are used for determining the fundamental parameters of the plasma.[9] The electron density

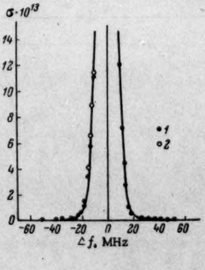

Fig. 2. Back-scattering cross section as a function of detuning Δf. He, $N = 6\cdot10^{10}$ cm^{-3}, $T_r = 5\cdot10^{4}$ K, λ_0 = 3.2 cm; 1) measurements; 2) points calculated from Eq. (19) for $\omega_s \leq \omega_{pi}$.

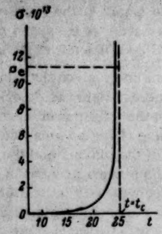

Fig. 3. The relation $\sigma_-(t)$ calculated from Eq. (19). He, $\Delta f = -10$ MHz, σ_e is the measured scattering cross section.

$\overline{N}_V$ averaged over the volume is determined from the measured phase shift and damping of the waves introduced by the plasma; the effective electron radiation temperature T_r is determined from measured thermal radiation power and the plasma absorption coefficient on the basis of the waveguide form of the Kirchhoff law. For example, in a helium discharge tube containing helium at p = 9 mm Hg, I_p = 70 mA, $\overline{N}_V = 6 \cdot 10^{10}$ cm^{-3}, and $T_r = 5 \cdot 10^4$°K.

In all cases, we observe a linear dependence of scattered energy on probing-signal power, which reaches 10 W in the continuous mode. The dependence of scattered power on plasma electron density is also observed to be linear.

Over the entire discharge current range of 10-150 mA the values of the measured scattering cross sections are considerably greater than those corresponding to scattering by fluctuations in an equilibrium plasma[2]. Figure 2 gives typical curves for the dependence of back-scattering cross sections on the detuning Δf in a rectangular waveguide containing a plasma (discharge tube length L = 100 mm). The experimental and theoretical data are in satisfactory agreement for comparatively small negative detuning $\Delta f = \omega_s/2\pi \lessapprox 15$ MHz. This is obviously evidence that we are dealing with scattering by ion-acoustic oscillations in a highly nonisothermal plasma under nearly critical conditions. For positive detuning, however, we have not obtained experimentally the significant reduction in scattering cross section predicted by theory in comparison with scattering for negative detuning.

Actually, the linear dependence of the scattered signal power (or σ_-) on $1/\omega_s^2$ is typical. It is easy to see such a dependence in Eq. (19) if we neglect the second term in comparison with the first for large $t \gg 1$ and $V_1 \to 0$. As has been shown,[8] one can determine the plasma density N approximately (and also the ratio V_s/V_1) from the slope of the line $\sigma_-(1/\omega_s^2)$ plotted from the experimental data (see Fig. 2).

Figure 3 shows the dependence of the scattering cross section σ_- on the parameter t of a nonisothermal plasma calculated from Eq. (19) for $\Delta f = -10$ MHz. As is evident, the value of the critical ratio t of the temperatures for a helium plasma is approximately 24.9. A comparison of the experimentally measured scattering cross section σ_e at the same detuning with the curve in Fig. 3 makes it possible to judge how nonisothermal the plasma is (in our case, $t \simeq 24.4$).

We note in conclusion that plasma inhomogeneity can have a significant effect on scattering by fluctuations; consideration of this effect and the effect of the bounded geometry on the spectral composition of the correlation functions in analytic studies of incoherent scattering should lead to a more complete agreement of experimental and theoretical results.

Multimode parametric interactions in a plasma with low-frequency pumping

Yu. M. Sorokin and N. S. Stepanov
N. I. Lobachevskii Gor'kii State University

(Submitted April 20, 1973)
Zh. Tekh. Fiz., 44, 291-299 (February 1974)

Multimode processes are analyzed in an isotropic, collisionless electron plasma whose density varies as a function of position and time under the influence of a low-frequency pumping wave. The spectrum of the high-frequency perturbation is assumed to be broad (on the scale of the pumping frequency) and smooth, so that the problem can be reduced to one of analyzing a single first-order partial differential equation for a complex amplitude. In this system, the perturbation spectrum can periodically shift upward or downward and undergo deformation, and the total wave energy can change. Synchronization of the pump with the high-frequency signal causes a monotonic shift of the spectrum upward (or downward), a simultaneous compression (or expansion) of the spectrum, and an increase (or decrease) in the total wave energy, depending on the particular phase relations. Both the boundary-value problem and the initial-value problem are solved.

1. An extensive literature has recently developed on the parametric interaction of waves in nonlinear dispersive media, particularly plasmas (see, e.g., refs. 1-9). The analysis of such processes generally reduces to an analysis of a system of truncated equations for waves which satisfy synchronism conditions. As sufficiently high-frequency photons merge and decay in slightly nonlinear dispersive media, the number of such waves turns out to be extremely limited, and in practice the process can be described completely on the basis of a three-wave interaction or a four-wave interaction. However, if the decay processes in a certain part of the spectrum involve photons of significantly lower frequencies, this model becomes inadequate, because the synchronous-interaction band, including that for systems with an appreciable dispersion, can include combination spectra of higher orders. For example, in a plasma with low-frequency pumping even in the case of a slight nonlinearity, the number of waves which interact effectively can increase significantly; this has been shown, in particular, by experiments on parametric regeneration in waveguide systems with long electron beams.[10] More recently, the excitation of a broad spectrum of combination harmonics has been observed[11] directly in a plasma column in the interaction of high-frequency electromagnetic waves with ion-acoustic waves; dynamic spectra of this interaction have been recorded.

Accordingly, there is much theoretical and practical interest in multimode processes in which the number of interacting harmonics is not specified beforehand and can, in principle, be infinite. It becomes a much more complicated matter to analyze a slightly dispersive nonlinear system when a large number of harmonics are taken into account, and finding a solution for a perturbation with an arbitrary spectrum is difficult. For this reason, analyses of such processes[12-15] have been based on at least two simplifying assumptions: The perturbation in the parameters of the medium by any of the interacting waves is small, and the dispersion of the system is neglected in the frequency range studied; outside this range the spectrum is arbitrarily cut off where necessary. The weak-nonlinearity approximation makes it possible to write the desired solution as an expansion in terms of a set of waves satisfying the dispersion relation of the unperturbed medium; neglecting the dispersion implies a constant frequency detuning for any of the elementary decay processes within the spectra range considered. However, in contrast with optical processes, the first of these assumptions can be easily violated in the case of microwave processes in a plasma when the pumping is strong or when the density of an electron beam is modulated. The second assumption becomes difficult to justify if combination harmonics of higher order are taken into account. Furthermore, for boundary perturbations (or initial perturbations, depending on the type of problem) including many spectral components, analysis of the solutions derived in refs. 12-15 becomes difficult, since the amplitude of each wave at a given spatial point is expressed in terms of the amplitudes specified at the boundaries of the medium for all waves. For this reason, the solutions have been analyzed in these papers for boundary conditions containing only two harmonics. An important consideration for further development of this problem, however, is the general conclusion[12-15] that the spectrum for the process expands and smooths considerably during the course of the specified interaction. Exploitation of this circumstance leads to important simplifications in the problems of parametric systems with low-frequency pumping (the restrictions mentioned above are also relaxed). Solutions having a broad but smooth spectrum are analyzed, in which case the amplitudes of the parametrically coupled harmonics are approximately equal, and the interactions among these harmonics can be described by means of purely differential equations, rather than differential—difference equations.

An approach of this kind was suggested previously for systems having periodically varying boundary conditions: a resonator with a vibrating wall[16] and a long line with a varying capacitive load.[17] Depending on the propagation time of the waves in the line (or resonator) and on the phase relations among the signal harmonics, a periodic or monotonic shift of the spectrum of the initial perturbation upward or downward, with a simultaneous expansion or compression of this spectrum and with a change in the total signal energy, becomes possible.[1)]

Below we use a similar method to study the parametric interaction of high-frequency waves in a density-modulated electron plasma in a homogeneous, nondispersive dielectric ($\varepsilon = \text{const}$, $\mu = 1$). This model can be thought of as an approximation to a semiconducting medium, or it can be associated with the presence of slow-wave systems in practical devices. We analyze the features of the transformation of the spectrum and energy of the waves in such a system, and we determine the conditions for the appearance of accumulative effects, both for a broad-band perturbation specified at the boundary of the medium and for the initial-value problem.

2. For brevity we restrict the analysis to the one-dimensional case. The basic features of the multimode interactions in this system are best analyzed on the basis of the highly simplified model of a cold, isotropic, collisionless plasma; in this case the propagation of transverse electromagnetic waves is described by the following linearized equations in the specified-field approximation and for a strong longitudinal (pump) wave:

$$\frac{\partial^2 A}{\partial z^2}-\frac{\varepsilon}{c^2}\frac{\partial^2 A}{\partial t^2}=\frac{\varepsilon}{c^2}\omega_{p0}^2[1+p\cos(\Omega t-Kz)]A. \tag{1}$$

This equation is written for the transverse component of the magnetic vector potential A (H = curl A, E = − (1/c) · ∂A/∂t); here $\omega_{p0} = [4\pi e^2 N_0/(m\varepsilon)]^{1/2}$ is the plasma frequency, e, m, and N_0 are the charge, mass, and unperturbed density of the electrons, and c is the speed of light.[2]

We turn first to the boundary-value problem. We assume that a broad-band perturbation with a uniformly spaced frequency spectrum $\omega_l = \Omega l$ is specified in the plasma at z = 0. The amplitudes of the spectral components, $a_l(0)$, are slowly varying functions of index l. This formulation of the problem could correspond, e.g., to the operation of a source at the plasma boundary which generates a periodic train of narrow pulses with period T = $2\pi/\Omega$ equal to the pumping period. Furthermore, as follows from the arguments in Sec. 1 and the experimental results of ref. 11, this boundary-value problem can be used to analyze the evolution of high-frequency decay processes in a plasma at large distances from the boundary, even when the approximations adopted in refs. 12-15 do not hold. It is also possible to reach certain general conclusions regarding the nature of the transformation of the signal spectrum and energy; these conclusions, in particular, supplement the results of refs. 12-15 in their range of applicability.

On this basis we seek a solution of Eq. (1) in the form

$$A(z,\ t)=\sum_{l\geqslant 1} a_l(z)\exp i(\Omega lt-k_l z+\delta l), \tag{2}$$

where the phase shift δ = const between adjacent harmonics evidently determines the position of the pulses exciting the system with respect to the pump wave, and the complex amplitude $a_l(z)$ is a slowly varying function of its argument z and its index l:

$$\frac{\partial a_l}{\partial z}\ll k_l a_l, \tag{3a}$$

$$|a_{l+1}-a_l|\ll a_l. \tag{3b}$$

Substituting (2) into (1), using condition (3a), and isolating from the resulting summation the terms which are harmonic in t at the same frequency [or, equivalently, averaging over t with a weight factor (− iΩlt)], we find the following equation for the complex amplitude a_l:

$$2k_l\frac{da_l}{dz}-i\gamma_l a_l-i\frac{\varepsilon p}{2c^2}\omega_{p0}^2\{a_{l-1}\exp i[(k_l-k_{l-1}-K)z-\delta] + a_{l+1}\exp i[(k_l-k_{l+1}+K)z+\delta]\}=0, \tag{4}$$

where $\gamma_l = k_l^2-(\varepsilon/c^2)(\omega_l^2-\omega_{p0}^2)$.

Solving differential–difference equation (4) for the general case is difficult, but under condition (3b) and under the assumption $l \gg 1$ we can treat the complex amplitudes a_l as continuous and smooth functions of argument l, setting

$$a_{l\pm 1}=a_l\pm\frac{\partial a_l}{\partial l}. \tag{5}$$

Furthermore, this multimode interaction can be important only in the case of a weak dispersion, so we can introduce the frequency detuning χ_l as follows:

$$k_l-k_{l-1}-K=\chi_l-\frac{1}{2}\frac{\partial\chi_l}{\partial l},\ k_{l+1}-k_l-K=\chi_l+\frac{1}{2}\frac{\partial\chi_l}{\partial l}. \tag{6}$$

Neglecting second-order terms in the spirit of inequalities (3a) and (3b), we find, after substituting (5) and (6) into (4), a first-order differential equation for $a_l(z)$:

$$2k_l\frac{\partial a_l}{\partial z}-\frac{\varepsilon p}{c^2}\omega_{p0}^2\exp\left(-\frac{i}{2}\frac{\partial\chi_l}{\partial l}z\right)\sin(\chi_l z-\delta)\frac{\partial a_l}{\partial l}-i\Psi_l(z)a_l=0, \tag{7}$$

where

$$\Psi_l(z)=\gamma_l+\frac{\varepsilon p}{c^2}\omega_{p0}^2\exp\left(-\frac{i}{2}\frac{\partial\chi_l}{\partial l}z\right)\cos(\chi_l z-\delta).$$

The solution of Eq. (7) satisfying the boundary condition $a_l(0) = a_{l_0}$ can be found by the method of characteristics,

$$a_l(z)=a_{l_0}\exp\left\{\frac{i}{2}\int\limits_{\xi(z,\ l)=\xi(0,\ l_0)}\Psi_l(z)k_l^{-1}dz\right\}, \tag{8}$$

if we know the integral $\xi(z, l)$ of the characteristic equation

$$\frac{\varepsilon p}{c^2}\omega_{p0}^2\exp\left(-\frac{i}{2}\frac{\partial\chi_l}{\partial l}z\right)\sin(\chi_l z-\delta)\,dz=-2k_l\,dl. \tag{9}$$

We emphasize that the form of the dispersion relation for wave system (2) has not, generally speaking, been specified (we have simply imposed the condition $\partial\chi_l/\partial l \ll \chi_l$). As shown below, this circumstance allows us to simplify Eq. (9) and to express its integral $\xi(z, l)$ in terms of elementary functions.

3. Multimode solution (8) found in Sec. 2 must obviously satisfy condition (3a) for any z, so we find the following inequalities:

$$\varepsilon\omega_{p0}^2 p\ll c^2k_l^2, \tag{10a}$$

$$|\gamma_l|\ll k_l^2. \tag{10b}$$

The first of these inequalities defines the spectral range in which a solution of this type holds, and the second serves essentially as a dispersion relation for wave system (2) used here. We see from (10b) that such a system can be constructed unambiguously in a certain (quite narrow) range, so we can ultimately choose this system at our convenience. From the physical point of view it seems natural to first analyze a set of waves satisfying the dispersion relation of a homogeneous plasma with a density $N_0(\gamma_l = 0)$. According to (2), this approach corresponds to the ordinary procedure of expanding the field in terms of waves of the unperturbed system. However, here the spectrum of wave numbers k_l (and thus the detuning χ_l) is not uniformly spaced, so it becomes difficult to analyze solution (8) [because of the need to integrate characteristic equation (9)].

Accordingly, for convenience in analyzing the resulting solution it is best to choose a system of waves with a uniform spacing of wave numbers k_l. The simplest system of this type is obviously a set of waves satisfying the dispersion relation of a retarding dielectric medium:

$$k_l^2 = \frac{\varepsilon}{c^2}\Omega^2 l^2. \tag{11}$$

The weak dispersion of real system (1) is taken into account in the phase factors in (8).

This set of waves satisfies requirement (10b) if

$$\varepsilon\omega_{p0}^2 \ll c^2 k_l^2, \tag{12}$$

i.e., in the high-frequency part of the spectrum; under these conditions inequality (10a) is automatically satisfied also.

According to (11) we have $\chi_l = \chi = (\sqrt{\varepsilon}/c)\Omega - K =$ const here and characteristic equation (9) can be integrated easily. For the characteristic passing through the point $l = l_0$ at $z = 0$, we find

$$l^2 = l_0^2 - \sigma_\sim[\cos\delta - \cos(\chi z - \delta)], \tag{13}$$

where $\sigma_\sim = (\sqrt{\varepsilon}/c)[\omega_{p0}^2 p/(\Omega\chi)]$. We see from (8) that the amplitudes of the harmonics $|a_l(z)|$ for wave system (11) remain constant along characteristics (13); only their phases change. Accordingly, with $\chi \neq 0$ in this system there is a shift of boundary-perturbation spectrum a_{l0} upward and downward which is periodic in z (with a period of $2\pi/\chi$). The modulation depth

$$l = \frac{1}{2}(l_{\max} - l_{\min}) = \frac{1}{2}\left|\sqrt{l_0^2 + \sigma_\sim(1 - \cos\delta)} - \sqrt{l_0^2 - \sigma_\sim(1 + \cos\delta)}\right|$$

turns out to be different for different characteristics.$^{3)}$ This wave-type shift occurs with respect to the average level

$$l = \frac{1}{2}(l_{\max} + l_{\min}) = \frac{1}{2}\left(\sqrt{l_0^2 + \sigma_\sim(1 - \cos\delta)} + \sqrt{l_0^2 - \sigma_\sim(1 + \cos\delta)}\right),$$

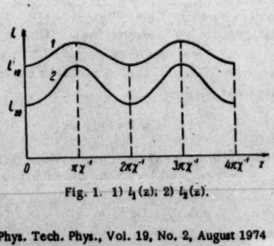

Fig. 1. 1) $l_1(z)$; 2) $l_2(z)$.

which is generally different from l_0. Thus the boundary-perturbation spectrum can either increase or decrease on the average, depending on the phase relations in the system. If, e.g., $\delta = 0$, and if the phase velocity of the pump wave satisfies $\Omega/K > (\sqrt{\varepsilon}/c)^{-1}$ $(\sigma_\sim < 0)$, there are no components at frequencies lower than at $z = 0$ at any $z \neq 0$. Figure 1 shows function (13) for this case, for two values of l_0.

We also see from these equations that there is a deformation of the spectrum as well as a shift and that this deformation is also periodic in z. Let us consider two arbitrary characteristics along which $l = l_1(z)$ and $l = l_2(z)$, where $l_1(0) = l_{10}$ and $l_1(0) = l_{20}$ (Fig. 1). We use the notation $\Delta l = l_1 - l_2$, $\Delta\sigma = l_1^2 - l_2^2$, where the functions $l_1(z)$ and $l_2(z)$ are evaluated at the same value of z, including $z = 0$: $\Delta l(0) = \Delta l_0$, $\Delta\sigma(0) = \Delta\sigma_0$. Then, by virtue of (13) we can write

$$\Delta\sigma = \Delta\sigma_0; \tag{14}$$

i.e., the square integral $\Delta\sigma$ remains constant along the characteristics. Equation (14) can be rewritten as

$$(l_1 + l_2)\Delta l = (l_{10} + l_{20})\Delta l_0, \tag{15}$$

from which we see that when the spectrum is shifted upward it broadens, and when it is shifted downward it contracts.

There is an analogous time transformation of the spectrum of broadband signals in a transmission line loaded by a periodically varying capacitance[17] if the propagation time of the waves in the line is not equal to a multiple of the period in the variation of the capacitance. The conclusion regarding periodic transformation of a high-frequency spectrum with nonvanishing detuning has been given previously,[14,15] but our approach gives a more complete picture of this process.

It is interesting to analyze the features of this spectral transformation in the case of "synchronism," in which case the phase velocities of the high-frequency transverse waves in (11) coincide with that of the longitudinal low-frequency wave:

$$c^2K^2 = \varepsilon\Omega^2. \tag{16}$$

Here $\chi \to 0$, and Eq. (13) can be rewritten as

$$l^2 = l_0^2 + \frac{\sqrt{\varepsilon}}{c}\frac{\omega_{p0}^2}{\Omega}\sin\delta z, \tag{17}$$

from which we see that the transformation of the spectrum is of an accumulative nature. For example, if $0 < \delta < \pi$, there is a monotonic upward shift of the spectrum and a simultaneous contraction, according to (15), while with $\pi < \delta < 2\pi$ there is a downward shift of the spectrum and a simultaneous expansion (Fig. 2). In the latter case the range of values of z over which this solution is valid is limited by inequality (12).

These conclusions agree, in particular, with the results of refs. 13-15, where it is noted that there can be a predominant transformation of the spectrum of decay processes in the case of zero tuning, toward higher or lower frequencies, depending on the sign of the difference between the coefficients of the nonlinear interaction for adjacent harmonics. The nature of the deformation of the spectrum was not studied.

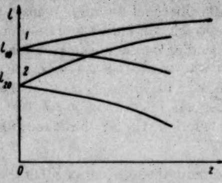

Fig. 2. 1) $l_1(z)$; 2) $l_2(z)$.

We note that a process of this type can also occur (as a function of the time) for the transmission line with a variable capacitive load[17] mentioned above, if the propagation time of the wave in the line is a multiple of the period of the changes in the capacitance. This condition obviously corresponds physically to the satisfaction of synchronism conditions (11), (16) with respect to the coordinate z. For the case of an ideal plane resonator with a vibrating boundary the monotonic upward shift of the spectrum is accompanied by an expansion, and the downward shift is accompanied by contraction, as shown in ref. 16.

4. The energy characteristic of this multimode process is evidently the time average of the energy flux density $\bar{S}$ in a specified cross section z = const. Since $a_l(z)$ is a slowly varying amplitude of the spectral component of vector potential **A**, the amplitudes of the corresponding components of the vectors **E** and **H** are approximately equal to $\omega_l c^{-1} a_l$ and $k_l a_l$, so that for a signal filling a spectral band Δl_0 at z = 0 we can write

$$\bar{S}=\frac{1}{4\pi\Delta t}\int\limits_{\Delta t} dt' \iint\limits_{\Delta l(\xi=\mathrm{const})} \omega_l k_{l'} a_l a_{l'}^*$$

$$\times \exp i[(\omega_l-\omega_{l'})t'-(k_l-k_{l'})z]\,dl\,dl'. \tag{18}$$

Since the solution of type (2) found above is periodic in t, the averaging interval Δt can be taken equal to Δt = T = 2π/Ω. Substituting dispersion relation (11) for the selected wave system into (18), we find

$$\bar{S}=\frac{\Omega^2\sqrt{\varepsilon}}{8\pi^2 c}\iint\limits_{\Delta l(\xi=\mathrm{const})} dl\,dl'\,a_{l'}^* a_l l' l$$

$$\times \exp i\left[\Omega\frac{\sqrt{\varepsilon}}{c}(l'-l)z\right]\int\limits_{-\pi}^{\pi}\exp i(l-l')\zeta\,d\zeta. \tag{19}$$

In evaluating the integral over ζ we must remember that the variable l is treated above as continuous only under the condition $l \gg 1$. Strictly speaking, l only takes on integer values, and in the exponential function in the integral over ζ the difference $l-l'$ cannot be less than unity. It is easy to see, however, that the variable l can again be assumed to be continuous here if the limits on the integration over ζ are extended to infinity. As a result we find from (19)

$$\bar{S}=\frac{\Omega^2\sqrt{\varepsilon}}{4\pi c}\int\limits_{\Delta l(\xi=\mathrm{const})}|a_l|^2 l^2\,dl$$

or, according to the mean-value theorem,

$$\bar{S}=\frac{\Omega^2\sqrt{\varepsilon}}{4\pi c}\Delta l\,(|a_l|^2 l^2)_{\xi=\xi_*} \tag{20}$$

along some characteristic ξ_*, which intersects the z = 0 boundary within the interval Δl_0. Substituting (15) into (20), we find the following energy relation for multimode interactions in systems of type (1):

$$\frac{\bar{S}(l_1+l_2)}{l_*^2}=\frac{\bar{S}_0(l_{10}+l_{20})}{l_{*0}^2}. \tag{21}$$

Accordingly, in this system an increase (or decrease) in the average frequency of the multimode process is accompanied by a simultaneous increase (decrease) in the waves and a simultaneous contraction (expansion) of their spectrum. It must be emphasized that Eq. (21) remains valid, not only for the entire broad-band signal, but also for any finite spectral interval Δl, of this signal, considered along the corresponding characteristics.

We also see from (21) that the energy transformations in a system having a large number of waves is generally a function of the perturbation spectrum specified at the boundary, since the nature of this spectrum determines the choice of characteristic ξ_* within interval Δl and thus the values of l_* and l_{*0} in (21). As spectral interval Δl is contracted this functional dependence becomes weaker and weaker, and in the limit $\Delta l/l \to 0$ we find

$$\frac{\bar{S}}{l}=\frac{\bar{S}_0}{l_0}, \tag{22}$$

which, by virtue of the periodicity of system (1), is essentially the familiar adiabatic variant for quasiharmonic wave packets in slightly inhomogeneous and slightly nonsteady-state dispersive media.[8,18] Accordingly, Eq. (21) can be thought of in a certain sense as a generalization of this invariant to the case of multimode (i.e., significantly nonharmonic) processes in systems of type (1) with periodically varying parameters.

5. As mentioned above, an equation like (8) for the wave set (11) is the solution of the boundary-value problem formulated here only under condition (12), i.e., in the high-frequency part of the spectrum. It should be noted, however, that with certain reasonable limitations on the spectral width of the unknown solution characteristic system (9) can be integrated in terms of elementary functions even for smaller values of ω_l, k_l. Let us analyze this possibility.

Before we choose a concrete wave system, the only limitations on the validity of solution (8) are inequalities (10a) and (10b). On the other hand, the circumstance that (9) can be integrated in terms of elementary functions becomes obvious when the spectrum of wave numbers k_l is spaced uniformly. We assume that within some band ($\Delta l \gg 1$) we have a set of waves satisfying these requirements. We write the dispersion relation of the desired system of waves as

$$k_l^2-\frac{\varepsilon}{c^2}(\Omega^2 l^2-\omega_{p0}^2)=\gamma_l,$$

where γ_l is some set of values (both positive and negative) which can be determined from the condition $k_l - k_{l-1} = \Delta =$ const and which satisfy inequality (10b).

It is easy to see that condition Δ = const leads to the following equation for γ_l:

$$\gamma_l = \frac{\varepsilon\omega_{p0}^2}{c^2}\left(1 - \frac{l^2}{l_s^2}\right), \tag{23}$$

where l_s is some fixed number for a given spectral band; this number should be chosen within interval Δl. Then, using (10a), we find from inequality (10b)

$$\frac{|l^2 - l_s^2|}{l_s^2} \leqslant p, \tag{24}$$

which, along with (10a), specifies the conditions for the applicability of solution (8) for the specified wave system.

This wave system satisfies the dispersion relation

$$k_l^2 = \frac{\varepsilon}{c^2}\Omega^2 l^2\left(1 - \frac{\omega_{p0}^2}{\Omega^2 l_s^2}\right), \tag{25}$$

which obviously corresponds to a piecewise-linear approximation of the dispersion curve of a homogeneous plasma with a density N_0 near frequency $\omega_s = \Omega l_s$.

We see from (25) that we should substitute into (8) and (9) the following:

$$\chi_l = \chi = \frac{\sqrt{\varepsilon}}{c}\Omega\left(1 - \frac{\omega_{p0}^2}{\Omega^2 l_s^2}\right) - Kl; \tag{26}$$

Using (23) we can then analyze solution (8) in detail, as in Secs. 3 and 4. Omitting the details, we note that for small modulation indices p this approach allows us to analyze the solution of system (1) at frequencies near the plasma frequency. However, the dispersion becomes important here, and the spectral width of the signal whose transformation can be treated by this method becomes narrower, in accordance with (24). For sufficiently high-frequency waves [see (12)] we can set $l_s \to \infty$; then we find the same results as in Secs. 3 and 4.

6. The initial-value problem can be treated in the same way. If, at t = 0, we specify in an unbounded system a perturbation which is periodic with respect to z and has a period $2\pi/K$, we can seek the solution of original equation (1) in the form

$$A(z, t) = \sum_{l \geqslant 1} a_l(t) \exp i(\omega_l t - Klz + \delta l). \tag{27}$$

Under the conditions

$$\frac{\partial a_l}{\partial t} \ll \omega_l a_l, \quad \frac{\partial a_l}{\partial l} \ll a_l, \quad \frac{\partial \vartheta_l}{\partial l} \ll \vartheta_l, \tag{28}$$

where ϑ_l is introduced on the basis of

$$\omega_{l+1} - \omega_l - \Omega = \vartheta_l + \frac{1}{2}\frac{\partial \vartheta_l}{\partial l}, \quad \omega_l - \omega_{l-1} - \Omega = \vartheta_l - \frac{1}{2}\frac{\partial \vartheta_l}{\partial l},$$

we find

$$2\omega_l \frac{\partial a_l}{\partial t} + \omega_{p0}^2 p \exp\left(\frac{i}{2}\frac{\partial \vartheta_l}{\partial l} t\right)\sin(\vartheta_l t + \delta)\frac{\partial a_l}{\partial l} - i\Phi_l(t) a_l = 0, \tag{29}$$

which is analogous to (7). Here

$$\Phi_l(t) = \frac{c^2}{\varepsilon}\gamma_l + \omega_{p0}^2 p \exp\left(\frac{i}{2}\frac{\partial \vartheta_l}{\partial l} t\right)\cos(\vartheta_l t + \delta).$$

Equation (29) can be solved by the method of characteristics, used in Sec. 2 for Eq. (7). The subsequent analysis does not differ from that of Secs. 3 and 4. For example, for wave systems satisfying the dispersion relation $\omega_l^2 = c^2/\varepsilon K^2 l^2$, with $\omega_l^2 \gg \omega_{p0}^2$ and $\vartheta = (c/\sqrt{\varepsilon})K - \Omega \neq 0$, we find a wave-type time shift of the spectrum of the initial perturbation with a period of $2\pi/\theta$. With $\Omega/K = c/\sqrt{\varepsilon}$, we find a monotonic upward or downward shift of the spectrum, depending on a phase of δ. The upward shift of the spectrum is accompanied by a contraction of the spectrum and an increase in the wave energy (in this case the energy density averaged over the period $L = 2\pi/K$), according to (14), (15), and (21). When the spectrum is shifted downward, it expands, and the energy density of the waves decreases.

As in the case of the boundary-value problem, the existence of cumulative effects at $\Omega/K = c/\sqrt{\varepsilon}$ corresponds to a parametric instability of this system with respect to the specified periodic perturbation.

---

1) There is a certain methodological analogy with refs. 14 and 15, where, in particular, the coefficients of the nonlinear interaction of excited combination harmonics were assumed to be weak functions of the harmonic indices; however, this assumption is not related to the approximation proposed above, which takes account of the spectral shape of the process under consideration.

2) Three-frequency processes for such a system are analyzed in ref. 3, where it is also shown that this approximation becomes invalid even at $|p| \ll 1$, if the group velocity of the electromagnetic waves approaches the phase velocity of the pump Ω/k.

3) The quadratic deviation $|\delta \sim| = (l_{max}^2 - l_{min}^2)/2$ is independent of the index l_0.

Kinetic theory for wave reflection from a moving plasma

Yu. V. Bogomolov

Radiotechnical Institute, Academy of Sciences of the USSR, Moscow

(Submitted June 11, 1973)
Zh. Tekh. Fiz., 44, 300-304 (February 1974)

The reflection of a plane electromagnetic wave at normal incidence on a moving plasma half-space is analyzed. The plasma is in a fixed magnetic field parallel to the plasma boundary. The spatial dispersion is assumed to be weak and the plasma boundary is specified by assuming diffuse reflection of electrons. The surface impedance is calculated for the ordinary wave and the extraordinary wave.

The interaction of electromagnetic radiation with a moving plasma is of interest in a variety of problems: the acceleration and diagnostics of plasmoids, amplification of radiowaves, and plasma containment by electromagnetic pressure. In practice this interaction is frequently realized in a slow-wave structure. To elucidate the main physical features of the problem, we consider a more abstract problem and assume that the electromagnetic field has the form of a plane wave and that the phase velocity of this wave is reduced by means of a dielectric. This model has been used for both isotropic plasmas[1] and a magnetoactive plasma.[2-5] In the latter case the magnetic field is perpendicular to the boundary.

In the present paper the problem is formulated as follows. We consider a half-space $x > 0$ filled with plasma. A constant magnetic field H_0, which is homogeneous within the plasma, is directed along the z axis parallel to the plasma boundary. The plasma boundary is simulated by the condition of diffuse reflection of electrons. We ignore the motion of the ions and collisions. It is assumed that the thermal motion of the electrons is weak and it is treated as a perturbation. The system of coordinates x, y, z is rigidly attached to the plasma. The plasma moves with velocity **V** parallel to the x axis. The entire space is filled with a dielectric of permittivity ε and magnetic permeability equal to unity in the laboratory frame. It is assumed that the dispersion of the dielectric is unimportant. Assume that a plane electromagnetic wave of arbitrary polarization is incident normally on the plasma. This wave can be split into two normal modes: $\mathbf{E} \parallel H_0$ (ordinary wave) and $\mathbf{E} \perp H_0$ (extraordinary wave). We wish to calculate the surface impedance for the two modes. Knowing the impedance, we can calculate the coefficients of reflection and absorption. We shall restrict ourselves to the case in which the phase velocity of the wave is greater than the plasma velocity.

Ordinary wave. It is simplest to solve the problem in the coordinate system attached to the plasma. In this system the dielectric moves along the x axis with velocity $V = \beta c$. We describe the plasma by a system of equations consisting of Maxwell's equations and a transport equation with self-consistent field for the electrons. We represent the electron distribution function in the form $f_0 + f$, where f_0 is the unperturbed (Maxwellian) distribution function and f is the correction associated with the wave. In a magnetic field parallel to the surface the electrons can be split into two groups. Some execute a periodic motion, knowing nothing of the surface. The penetration of a field into a plasma consisting of only such electrons has been considered (in the absence of a dielectric) by Dnestrovskii and Kostomarov.[6] Other electrons are constantly colliding with the boundary, being scattered diffusely on it. The condition of diffuse reflection takes the form $f = 0$ at the boundary.

The solution of the linearized transport equation

$$-i\omega f + v\cos\delta\frac{\partial f}{\partial x} + \omega_H\frac{\partial f}{\partial \delta} = \frac{e}{m}\frac{\partial f_0}{\partial v_z}E_z \tag{1}$$

for the diffuse boundary has the form

$$f(x,\delta) = \frac{e}{m\omega_H}\frac{\partial f_0}{\partial v_z}\left[(e^{-2\pi\mu}-1)^{-1}\eta(x-x_0)\int\limits_{\delta}^{\delta+2\pi} + \eta(x_0-x)\right] \times e^{\mu(\delta-\delta')}E_z(x')\,d\delta', \tag{2}$$

Here, v and δ are polar coordinates in the velocity space; $\omega_H = eH_0/mc$ is the electron gyrofrequency; $\mu = i\omega/\omega_H$; δ_0 is the angle at which an electron leaves the wall; $\eta(\zeta)$ is the step function, equal to zero for $\zeta < 0$ and unity for $\zeta > 0$. Further, x_0, δ_0, x' are defined by

$$\left.\begin{aligned} x_0 &= \frac{v}{\omega_H}(\sin\delta + 1), \\ \delta_0 &= \arcsin\left(\sin\delta - \frac{x\omega_H}{v}\right), \\ x' &= x + \frac{v}{\omega_H}(\sin\delta' - \sin\delta). \end{aligned}\right\} \tag{3}$$

The function f_0 has the form

$$f_0 = N\left(\frac{m}{2\pi T}\right)^{3/2}\exp\left[-\frac{m}{2T}(v^2 + v_z^2)\right], \tag{4}$$

where N is the number of electrons in 1 cm^3 and T is the temperature in energy units. The time factor $\exp(-i\omega t)$ is omitted throughout.

In the ordinary wave, only the components E_z, D_z, H_y, B_y, j_z are nonvanishing. Maxwell's equations are

$$\left.\begin{aligned} \frac{dH_y}{dx} &= -ikD_z + \frac{4\pi}{c}j_z, \\ \frac{dE_z}{dx} &= -ikB_y, \end{aligned}\right\} \tag{5}$$

where $k = \omega/c$. These equations must be augmented by the material equations, which (in the case of a moving dielectric) take the form of Minkowski's relations[7]

$$D_z = \varepsilon a E_z + bH_y, \quad B_y = aH_y + bE_z, \tag{6}$$

where

$$a = \frac{1-\beta^2}{1-\varepsilon\beta^2}, \quad b = \frac{\beta(\varepsilon-1)}{1-\varepsilon\beta^2}.$$

Substituting (6) into (5) and eliminating H_y, we find

$$\frac{d^2E_z}{dx^2}+2ikb\frac{dE_z}{dx}+k^2(\varepsilon a^2-b^2)E_z=-\frac{4\pi ika}{c}j_z. \tag{7}$$

Note that the term with the first derivative arises solely because of the motion of the dielectric. The current j_z is related to f by

$$j_z=-e\int_0^\infty v\,dv\int_{-\pi/2}^{3\pi/2}d\delta\int_{-\infty}^{\infty}v_z f\,dv_z. \tag{8}$$

The given range of variation of the angle δ is obvious for a particle colliding with the boundary. For a cold plasma, $j_z=-(\omega_0^2/4\pi i\omega)E_z$, where $\omega_0=\sqrt{4\pi e^2N/m}$ is the plasma frequency. In this case, the plasma can be described by the permittivity $\varepsilon_0=1-\omega_0^2/\omega^2$.

We introduce an operator $I_z(E_z)$, which vanishes for a cold plasma:

$$I_z(E_z)=-\frac{\omega_0^2}{c^2}E_z-\frac{4\pi i\omega}{c^2}j_z. \tag{9}$$

Then Eq. (7) becomes

$$\frac{d^2E_z}{dx^2}+2ikb\frac{dE_z}{dx}+k^2\left(\varepsilon a^2-b^2-\frac{a\omega_0^2}{\omega^2}\right)E_z=aI_z(E_z). \tag{10}$$

For the space outside the plasma,

$$\frac{d^2E_z}{dx^2}+2ikb\frac{dE_z}{dx}+k^2(\varepsilon a^2-b^2)E_z=0. \tag{11}$$

We seek a solution of Eqs. (10)-(11) in the form

$$E_z=E_{z0}+u_z, \tag{12}$$

where E_{z0} corresponds to a cold plasma, and u_z characterizes the thermal motion. We consider the case of weak spatial dispersion

$$\frac{kv}{\omega_H}\ll 1. \tag{13}$$

If inequality (13) holds, u_z can be regarded as a perturbation:

$$u_z\ll E_{z0}. \tag{14}$$

For E_{z0} in the "subluminous" case $(1-\varepsilon\beta^2>0)$ we have the well-known expressions (the incident wave has amplitude unity)

$$E_{z0}(x)=\begin{cases}\dfrac{2\sqrt{\varepsilon}}{\sqrt{\varepsilon}+M}\exp(ih_1x)\ (x>0),\\ \exp\left(ik\dfrac{\sqrt{\varepsilon}+\beta}{1+\sqrt{\varepsilon}\beta}x\right)+\dfrac{\sqrt{\varepsilon}-M}{\sqrt{\varepsilon}+M}\exp(-ih^{\text{refl}}x)\ (x<0),\end{cases} \tag{15}$$

where

$$M=\sqrt{\varepsilon-\frac{\omega_0^2}{\omega^2 a}},\ h_1=-kb+kaM,\ h^{\text{refl}}=k\frac{\sqrt{\varepsilon}-\beta}{1-\sqrt{\varepsilon}\beta}.$$

Substituting (12) into (10)-(11) and taking into account (14), we obtain equations for the function $u_z(x)$:

$$u_z''+2ikbu_z'+k^2\left(\varepsilon a^2-b^2-\frac{a\omega_0^2}{\omega^2}\right)u_z=aI_z(E_{z0})\ (x>0), \tag{16}$$

$$u_z''+2ikbu_z'+k^2(\varepsilon a^2-b^2)u_z=0\ (x<0). \tag{17}$$

We solve Eq. (16) by variation of constants, remembering that the solution is bounded at $x=\infty$; we take account of the radiation condition in the solution of (17). On the boundary $x=0$ we require continuity of u_z and du_z/dx. For $u_z(x)$ outside the plasma we obtain the expression

$$u_z(x)=B\exp(-ih^{\text{refl}}x), \tag{18}$$

where

$$\left.\begin{aligned}B&=\frac{a}{i(h_1+h^{\text{refl}})}\int_0^\infty e^{-ih_2s}I_z(E_{z0}(s))\,ds,\\ h_2&=-kb-kaM.\end{aligned}\right\} \tag{19}$$

We write down the expression for B in more detail. For this case, we must first take account of Eqs. (2), (8), (9), and (15) and integrate with respect to v_z. We then introduce a new variable δ_0 in place of s in the part of (19) that corresponds to collisions of electrons with the boundary. The relationship between δ_0 and s is

$$s=(v/\omega_H)(\sin\delta-\sin\delta_0). \tag{20}$$

In the remaining part of (19) we can integrate with respect to s directly. Remembering this and making some simple identity transformations, we find

$$B=-\frac{2a\sqrt{\varepsilon}\omega_0^2}{c^2(\sqrt{\varepsilon}+M)(h_1+h^{\text{refl}})(h_1-h_2)}W, \tag{21}$$

where

$$\begin{aligned}W={}&1+\frac{\mu m}{2\pi T}(e^{-2\pi\mu}-1)^{-1}\\ &\times\int_0^\infty v\exp\left[i\frac{v}{\omega_H}(h_1-h_2)\right]dv\int_0^{2\pi}d\delta\int_\delta^{\delta+2\pi}\Phi\,d\delta'\\ &-\frac{i\mu m(h_1-h_2)}{2\pi\omega_HT}\int_0^\infty v^2dv\int_{-\pi/2}^{\pi/2}\cos\delta_0\\ &\times\exp\left[-i\frac{v}{\omega_H}(h_1-h_2)\sin\delta_0\right]d\delta_0\int_{\delta_0}^{\pi-\delta_0}d\delta\int_{\delta_0}^{\delta}\Phi\,d\delta',\end{aligned} \tag{22}$$

$$\Phi=\exp\left[-\frac{mv^2}{2T}+\mu(\delta-\delta')+i\frac{v}{\omega_H}(h_1\sin\delta'-h_2\sin\delta)\right]. \tag{23}$$

We define the impedance Z by

$$Z\equiv R+iX=-\frac{E_z(0)}{H_y(0)}. \tag{24}$$

The most interesting case is the one in which the wave is a skin wave (M purely imaginary). Using (6), (5), (12), and (18), we find

$$Z=\frac{1}{M}\left(1-\frac{i\omega_0^2}{2a\omega^2M^2}\operatorname{Im}W\right). \tag{25}$$

Expanding W in a series in h_1v/ω_H and h_2v/ω_H (k, h_1, h_2 are of the same order), we find

$$\operatorname{Im}W=a|M|\left(\frac{2T}{\pi mc^2}\right)^{1/2}\left(1+\frac{\cos^2\pi\Omega}{4\Omega^2-1}\right), \tag{26}$$

where $\Omega=\omega/\omega_H$. Hence,

$$Z=\left(\frac{T}{2\pi mc^2}\right)^{1/2}\frac{a\omega_0^2}{\omega_0^2-\varepsilon a\omega^2}\left(1+\frac{\cos^2\pi\Omega}{4\Omega^2-1}\right)-i\left(\frac{\omega_0^2}{\omega^2a}-\varepsilon\right)^{-1/2}. \tag{27}$$

The complex reflection coefficient r is related to the impedance by

$$r=\frac{\sqrt{\varepsilon}Z-1}{\sqrt{\varepsilon}Z+1}. \tag{28}$$

The absorption coefficient A, which is defined by

$$A=1-|r|^2, \tag{29}$$

is

$$A=2a\left(\frac{2\varepsilon T}{\pi mc^2}\right)^{1/2}\left(1+\frac{\cos^2\pi\Omega}{4\Omega^2-1}\right). \tag{30}$$

Thus, the thermal motion of the electrons leads to absorption of the electromagnetic wave. The absorption has a surface character and is due to the fact that the electric field of the wave performs work on an electron that collides with the boundary. The absorption is of the order of the ratio of the mean electron thermal velocity to the velocity of light. If ε = 1, then a = 1 and Eq. (30) goes over into the well-known expression.[8,9]

Extraordinary wave. If an extraordinary wave is incident on the plasma a longitudinal field E_x arises. With regard to this component of the field, we shall also assume that perturbation theory applies. Omitting the intermediate calculations, we write down the impedance $Z = E_y(0)/H_z(0)$ for "subluminous" motion of the plasma and skinning of the wave:

$$Z=\left(\frac{T}{2\pi mc^2}\right)^{1/2}\frac{a\omega^2\omega_0^2F}{\omega_0^2(\varepsilon\omega^2-\omega_0^2)-\varepsilon a\omega^2[\varepsilon(\omega^2-\omega_H^2)-\omega_0^2]}$$
$$-i\left(\frac{\omega_0^2}{\omega^2a}\frac{\omega_0^2-\varepsilon\omega^2}{\omega_0^2-\varepsilon(\omega^2-\omega_H^2)}-\varepsilon\right)^{-1/2}, \tag{31}$$

where

$$F=\frac{1}{\varepsilon(\Omega^2-1)-\Omega_0^2}\left\{2\varepsilon^2+\frac{(\Omega_0^2-\varepsilon\Omega^2)^2}{\Omega^2}+\frac{3\cos^2\pi\Omega}{(1-4\Omega^2)(9-4\Omega^2)}\right.$$
$$\left.\times\left[6\varepsilon^2+8\varepsilon(\varepsilon\Omega^2-\Omega_0^2)+\left(4-\frac{3}{\Omega^2}\right)(\varepsilon\Omega^2-\Omega_0^2)^2\right]\right\}, \tag{32}$$

$$\Omega_0=\omega_0/\omega_H.$$

The radicand in the imaginary part of the impedance is positive (skin wave). The absorption coefficient is

$$A=2a\left(\frac{2\varepsilon T}{\pi mc^2}\right)^{1/2}\frac{\omega^2F}{\omega_0^2-\varepsilon\omega^2}. \tag{33}$$

As for the ordinary wave, the absorption is proportional to $\sqrt{T}$. If ε = 1, Eq. (33) goes over into the well-known expression.[10]

The above expressions have been written down in the coordinate system attached to the plasma. The absorption coefficient in the laboratory frame is

$$A_{\text{lab}}=\left(\frac{1+\sqrt{\varepsilon}\beta}{1-\sqrt{\varepsilon}\beta}\right)^2A. \tag{34}$$

I should like to thank M. L. Levin for discussion.

Scattering of high-frequency electromagnetic waves by ion-acoustic oscillations in a bounded plasma

V. G. Shaptala

A. M. Gor'kii Khar'kov State University

(Submitted April 9, 1973)
Zh. Tekh. Fiz., 42, 305-310 (February 1974)

The scattering of a high-frequency electromagnetic wave by regular ion-acoustic oscillations is studied in a plane homogeneous plasma with and without a fixed magnetic field parallel to the plasma boundary. The problem is treated in the hydrodynamic approximation and the nonlinearity is assumed to be weak. Expressions are found for the electromagnetic waves emitted into the vacuum at frequencies $\Omega_n = \Omega + n\omega$ (Ω is the frequency of the electromagnetic wave and ω is the frequency of the ion-acoustic wave, $n = \pm 1, \pm 2, \ldots$) for the case of total internal reflection and for transparency. It is shown that the amplitude of the scattered wave increases as the frequency of the probing signal approaches the plasma frequency.

1. The scattering of high-frequency electromagnetic waves by low-frequency fluctuations of a stable and turbulent plasma has been studied and is used for plasma diagnostics.[1,2] However, under certain conditions, for example when beams of charged particles pass through a plasma, regular low-frequency oscillations are excited in the plasma with an amplitude that exceeds appreciably the amplitudes of the fluctuating fields. If high-frequency probing of such a plasma is used, radiation is emitted at combination frequencies and this reflects the dynamics of the interaction between the regular high- and low-frequency waves.

Study of the characteristics of the scattered waves can yield additional information on the processes that take place in the plasma and on its parameters. In the present paper we consider the scattering of high-frequency electromagnetic waves by regular ion-acoustic oscillations of a plane plasma with and without a fixed magnetic field. General questions and special cases involving the nonlinear interaction of waves in a bounded plasma have been investigated in refs. 3-6.

2. We consider a plane-parallel layer $0 < x < 2d$ of homogeneous nonisothermal plasma ($T_e \gg T_i$, where T_α is the temperature of the plasma particles) in which there propagates an ion-acoustic wave $\varphi \propto \exp[i(q_z z - \omega t)]$, where φ is the electric potential. Assume that a high-frequency plane wave is incident on the boundary $x = 0$ from the vacuum side:

$$\mathbf{E}_0^v = \mathscr{E} e^{i(\mathbf{kr} - \Omega t)}, \quad k = \frac{\Omega}{c}, \quad \Omega \gg \omega. \tag{1}$$

The nonlinear interaction of the low- and high-frequency waves gives rise to electromagnetic oscillations at the combination frequencies $E_n \propto \exp[i(\xi_{nx}x + k_{n\tau}r_\tau - \Omega_n t)]$, and these are radiated into the vacuum:

$$\mathbf{E}_n^v = e^{i(\mathbf{k}_{n\tau}\mathbf{r}_\tau - \Omega_n t)} \begin{cases} \mathscr{E}_n \exp(-ik_{nx}x), \\ \mathscr{E}_n' \exp(ik_{nx}x), \end{cases} \tag{2}$$

where $k_{n\tau} = k_\tau + nq_z$, $k_{nx} = (k_n^2 - k_{n\tau}^2)^{1/2}$, $k_n = \Omega_n/c$, $\Omega_n = \Omega + n\omega$, $n = \pm 1, \pm 2, \ldots$; $\mathscr{E}_n$ and $\mathscr{E}_n'$ are the amplitudes of the scattered waves reflected from the boundary of the plasma and transmitted through the layer that we wish to determine. We assume that the plasma is fairly broad for the high-frequency wave and that its boundaries are sharp, i.e., $2d\,|\xi_{nx}| \gg 1$, $l\,|\xi_{nx}| \ll 1$, where l is the width of the transition region of inhomogeneous plasma.

In the approximation of weak nonlinearity

$$\left(\frac{e\varphi}{m_e v_{Te}^2},\ \frac{eE_n}{m_e \Omega_n c} \ll 1\right)$$

the interaction between the low- and high-frequency waves is described by a system of coupled nonlinear wave equations augmented by the nonlinear boundary conditions for the fields at the plasma–vacuum interface.[5,6]

In the case of total internal reflection of the high-frequency waves from the layer and also when they propagate in the plasma with appreciable phase difference ($\Delta = \xi_{nx} - \xi_{n-1x} - q_x \sim \xi_{nx}$) the change in the amplitudes of the interacting waves can be ignored (prescribed-field approximation).

In the resonance case ($\Delta \gg \xi_{nx}$) one can only find the boundary values of the amplitudes of the high-frequency waves in this approximation and for $x > 1/\xi_{nx}$, $1/q_x$ one must take account of the x dependence of the amplitudes of the interacting waves:

$$\begin{gathered} \varphi = b_1(x) e^{iq_x x} + b_2(x) e^{-iq_x x}, \\ E_n = A_n^+(x) e^{i\xi_{nx} x} + A_n^-(x) e^{-i\xi_{nx} x}. \end{gathered} \tag{3}$$

If we ignore the high-frequency waves reflected from the second boundary of the layer (this is valid if the reflection coefficients are small, $R_n \ll 1$), from the nonlinear wave equations (see, for example, refs. 3-4) we obtain the following system of dynamical equations,

$$\left.\begin{aligned} 2i\frac{\partial b_1}{\partial x} &= V_{bA} \sum_n A_n A_{n-1}^* e^{i\Delta_1(n,\, n-1)x}, \\ 2i\frac{\partial b_2}{\partial x} &= -V_{bA} \sum_n A_n A_{n-1}^* e^{i\Delta_2(n,\, n-1)x}, \\ 2i\frac{\partial A_n}{\partial x} &= V_{AA}\left[b_1 A_{n-1} e^{i\Delta_1(n-1,\, n)x} + b_2 A_{n-1} e^{i\Delta_2(n-1,\, n)x}\right. \\ &\quad \left. + b_1^* A_{n+1} e^{i\Delta_1(n+1,\, n)x} + b_2^* A_{n+1} e^{i\Delta_2(n+1,\, n)x}\right], \end{aligned}\right\} \tag{4}$$

where $\Delta_{1,2}(n, n-1) = \xi_{nx} - \xi_{n-1x} \pm q_x$, and V_{bA} and V_{AA} are the wave-coupling coefficients, whose weak dependence on n can be ignored. The solution of the system of equations (4), which is found in ref. 7, is

$$\left.\begin{aligned} A_n(x) &= \sum_{m=-\infty}^{\infty} A_m(0)\, i^{n-m} e^{i(n-m)\beta} J_{n-m}(V_{AA}|B(x)|), \\ b_{1,2}(x) &= b_{1,2}(0) \\ &\pm \frac{V_{bA}}{2\Delta_{1,2}(n,\, n-1)}\left[1-e^{i\Delta_{1,2}(n,\,n-1)x}\right]\sum_n A_n(0)A^*_{n-1}(0), \\ B(x) &= \int_0^x \left[b_1(x)e^{i\Delta_2(n-1,\,n)x}+b_2(x)e^{i\Delta_1(n-1,\,n)x}\right]dx, \end{aligned}\right\} \quad (5)$$

where $\beta = \arg B$ and J_n is a Bessel function.

We shall consider the scattering of high-frequency waves by ion-acoustic oscillations of a plasma layer in two cases.

3. Assume that a symmetric ion-acoustic wave is excited in an isotropic plasma:

$$\varphi = \cos q_x(x-d)\, e^{i(q_z z-\omega t)}. \quad (6)$$

If $\omega \ll \omega_{pi}$, then $q_x \approx \pi/d$ and $q_z = (q_s^2 - q_x^2)^{1/2}$, where $q_s = \omega/v_s$ is the wave number of the ion acoustic wave, $v_s = [\gamma(T_e/m_i)]^{1/2}$, γ is the adiabatic exponent, and $\omega_{p\alpha} = (4\pi e^2 n_0/m_\alpha)^{1/2}$ is the plasma frequency.

Assume that the probing high-frequency wave is incident at normal incidence on the boundary $x = 0$ and that its electric field is at right angles to the plane of propagation of the ion acoustic wave ($\mathcal{E}_{0y} = \mathcal{E}_0$). The scattered waves have the same polarization ($E_{ny} = E_n$) and are radiated into the vacuum at the angles $\theta_n = \operatorname{arc\,tg}(nq_z)/k_n$.

The system of nonlinear wave equations that describes the interaction of the ion-acoustic and electromagnetic high-frequency waves in the hydrodynamic approximation ($\xi_n u \ll \Omega_n$, $qu \gg \omega$) has the form

$$\left.\begin{aligned} \Delta\mathbf{E}_n + \xi_n^2\mathbf{E}_n &= \frac{e\omega_{pe}^2}{2m_e u^2 c^2}(\varphi\mathbf{E}_{n-1}+\varphi^*\mathbf{E}_{n+1}), \\ \Delta(\Delta\varphi + q_s^2\varphi) &= -\frac{eq_s^2}{2m_e\Omega^2}\sum_n(\xi_n-\xi_{n-1})^2\mathbf{E}_n\mathbf{E}^*_{n-1}, \end{aligned}\right\} \quad (7)$$

where $u = [\gamma(T_e/m_e)]^{1/2}$, $\xi_n^2 = k_n^2(1-\omega_{pe}^2/\Omega_n^2) = k_n^2\varepsilon_n$.

We ignore collisions and the motion of the ions in the field of the high-frequency waves.

The fields of the interacting waves satisfy the following boundary conditions at the plasma–vacuum interface:

$$\left.\begin{aligned} (E_n^p - E_n^v)\big|_{x=0,\,2d} = 0,\ \left(\frac{\partial E_n^p}{\partial x}-\frac{\partial E_n^v}{\partial x}\right)\Big|_{x=0,\,2d} &= 0 \\ v_{\omega x}\big|_{x=0,\,2d} = 0,\ (\varphi^p-\varphi^v)\big|_{x=0,\,2d} &= 0, \\ \left(\frac{\omega_{pi}^2}{\omega^2}\frac{\partial\varphi^p}{\partial x}+\frac{\partial\varphi^v}{\partial x}\right)\Big|_{x=0,\,2d}& \\ = -\frac{i\, e\omega_{pe}^2 q_x^2}{2m_e\omega^2\Omega^2 q_s^2}\sum_n \Delta_1(n,\, n-1)\,\mathbf{E}_n\mathbf{E}^*_{n-1}\big|_{x=0,\,2d}&. \end{aligned}\right\} \quad (8)$$

Let us consider first the generation of scattered waves when they undergo total internal reflection from the plasma ($\xi_{nx}^2 < 0$). Ignoring the change in the amplitudes of the interacting waves, we obtain the following equation for the wave amplitudes at the combination frequencies from Eqs. (7) and the boundary conditions (8):

$$\mathcal{E}_n = E_n(0) = -\frac{e\varphi_0\omega_{pe}^2}{2m_e u^2c^2(k_{nx}+\xi_{nx})}\left[\frac{\xi_{nx}+\xi_{n-1x}}{(\xi_{nx}+\xi_{n-1x})^2-q_x^2}E_{n-1}(0) + \frac{\xi_{nx}+\xi_{n+1x}}{(\xi_{nx}+\xi_{n+1x})^2-q_x^2}E_{n+1}(0)\right], \quad (9)$$

where

$$\xi_{nx}^2 \approx \xi^2 + 2n\frac{\Omega\omega}{c^2} - (nq_z)^2.$$

The interaction of the waves becomes stronger if the high-frequency signal is cut off, i.e., if $\Omega \lessapprox \omega_{pe}$, so that $\xi^2 \ll (nq_z)^2$. In this case when $q_s d \gg \pi$, $q_x \ll q_z$ it follows from Eq. (8) that

$$\mathcal{E}_n = 2\mathcal{E}_0\left(-\operatorname{sg} n\,\frac{e\varphi_0}{2m_e u^2}\frac{k}{q_z}\right)^{|n|}\prod_{j=1}^{|n|}\frac{1}{2j-1}, \quad (10)$$

where

$$\operatorname{sg} n = \begin{cases} -1 & n<0, \\ 1 & n>0. \end{cases}$$

If $q_s d \approx \pi$, so that $q_z^2 \ll q_s^2$, $\omega\Omega/c^2$, the amplitudes of the waves scattered into the vacuum are

$$\mathcal{E}_n = 2\mu\mathcal{E}_0\left(\frac{e\varphi_0 k^2}{m_e u^2 q_s^2}\sqrt{\frac{\omega}{2\Omega}}\right)^{|n|}\prod_{j=1}^{|n|}\sqrt{j}+\sqrt{j-1}, \quad (11)$$

where

$$\mu = \begin{cases} 1 & n>0, \\ i^{|n|} & n<0. \end{cases}$$

For an arbitrary polarization of the probing wave with respect to the plane of propagation of the ion acoustic wave, and also if its front is not strictly parallel to the boundary of the plasma, electron plasma waves are excited in the plasma when $\Omega \approx \omega_{pe}$ at the frequencies Ω_n: $E_n^l \propto \exp(i\xi_{nx}^l x)$, $\xi_{nx}^l = (\Omega_n/u)(\varepsilon_n)^{1/2}$. If $\xi_{nx}^l \gg nq_z$, i.e., the electron plasma waves propagate at almost right angles to the plasma boundary, the emission into the vacuum is determined by the electromagnetic waves $E_n \propto \exp(i\xi_{nx}x)$, and (10) and (11) remain valid.

If the frequency of the probing signal satisfies $\Omega > \omega_{pe}$, so that the scattered waves propagate in the plasma ($\xi_{nx}^2 > 0$, $R_n \ll 1$) with small phase difference [$\Delta(n, n-1) \approx q_x \ll \xi_{nx}$], their amplitudes change with the coordinate x in accordance with (5). In this case, the coupling coefficients and the boundary values of the high-frequency waves are given by

$$\left.\begin{aligned} V_{AA} = \frac{e\omega_{pe}^2}{2m_e u^2c^2\xi},\quad V_{bA} &= -\frac{e\omega^2}{m_e v_s^2\Omega^2 q_x}\left[1+\frac{q_z^2u^2(q^2-q_s^2)}{\omega^2q^2}\right], \\ A_n(0) &= \mathcal{E}_0\left(-\frac{e\varphi_0\omega_{pe}^2}{8m_e u^2\Omega^2}\right)^{|n|} \end{aligned}\right\} \quad (12)$$

Substituting these equations into (5) we find from the boundary conditions (8) the amplitudes of the scattered waves transmitted through the layer into the vacuum:

$$\mathcal{E}'_n = \frac{2\xi_{nx}}{\xi_{nx} + k_{nx}} e^{i2d(\xi_{nx} - k_{nx})} \sum_{m=-\infty}^{\infty} A_m(0)\, i^{n-m} J_{n-m}(\chi d), \tag{13}$$

where

$$\chi = \frac{e\varphi_0}{8m_e u^2}\left(\frac{e\mathcal{E}_0}{m_e v_e \Omega}\right)^2 \xi.$$

If $\chi d < 1$, and the frequency of the probing wave is sufficiently high that $\xi_{nx} \approx k_{nx}$, the expression (12) simplifies to

$$\mathcal{E}'_n \approx A_n(0)\, J_0(\chi d) + i\,(A_{n+1} + A_{n-1})\, J_1(\chi d). \tag{14}$$

4. We now consider a symmetric ion-acoustic wave (5) propagating in a layer of magnetoactive plasma ($H_0 \| z$). In the frequency range $\omega \ll \omega_{Hi} \ll \omega_{pi}$, the components of the wave vector of the ion acoustic wave are

$$q_x \approx \frac{\pi}{d}, \quad q_z = \left(\frac{\omega^2}{\omega_{Hi}^2} q_x^2 + q_s^2\right)^{1/2},$$

where $\omega_{H\alpha} = (e_\alpha H_0)/(m_\alpha c)$ is the cyclotron frequency of the plasma particles. Suppose the high-frequency probing wave is incident normally on the boundary $x = 0$. We restrict ourselves to the case in which the scattered waves propagate almost at right angles to the external magnetic field, i.e., $\xi_n, \varkappa_n \gg n q_z$, where $\xi_n = k_n(\varepsilon_n)^{1/2}$,

$$\varkappa_n = k_n \left[\frac{(\Omega_n^2 - \omega_{pe}^2)^2 - \omega_{He}^2 \Omega_n^2}{\Omega_n^2 (\Omega_n^2 - \omega_{He}^2 - \omega_{pe}^2)}\right]^{1/2}$$

are the wave numbers of the ordinary and the extraordinary wave for transverse propagation. In this case, the coupling between the ordinary and the extraordinary high-frequency waves can be ignored, i.e., a probing wave with electric field parallel or perpendicular to the external constant magnetic field will excite scattered waves of the same polarization.

The nonlinear equations for the interacting waves in the hydrodynamic approximation ($\varkappa_n u$, $\xi_n u \ll \Omega_n$, $q_z u \gg \omega$, $q_x u \ll \omega_{He}$) are

$$\left.\begin{aligned} &\frac{\partial^2 \varphi}{\partial x^2} - \frac{\omega_{Hi}^2}{\omega^2}(q_z^2 - q_s^2)\,\varphi = -\frac{2\pi e n_0 \omega_{Hi}}{u^2 \omega_{pi}^2} \sum_n \mathbf{v}_n \mathbf{v}^*_{n-1}, \\ &\operatorname{curl}\operatorname{curl} \mathbf{E}_n - \varepsilon_n k_n^2 \mathbf{E}_n = -\frac{2\pi e n_0 \Omega_n}{c^2 \omega}(\mathbf{v}_{n-1} \nabla \mathbf{v}_\omega + \mathbf{v}_{n+1} \nabla \mathbf{v}^*_\omega), \end{aligned}\right\} \tag{15}$$

where

$$\left.\begin{aligned} &\mathbf{v}_n = -\frac{ie\Omega_n}{m_e(\Omega_n^2 - \omega_{He}^2)}\left(\mathbf{E}_n - \frac{\omega_{He}^2}{\Omega_n^2}\mathbf{h}(\mathbf{h}\mathbf{E}_n) + i\frac{\omega_{He}}{\Omega_n}\mathbf{h} \times \mathbf{E}\right), \\ &\mathbf{v}_\omega = \frac{e\omega(\omega^2 \mathbf{q} + i\omega_{He}\mathbf{h} \times \mathbf{q} - \omega_{He}^2 q_z \mathbf{h})}{m_e[\omega^2(\omega_{He}^2 - \omega^2 + q^2u^2) - \omega_{He}^2 q_z^2 u^2]}, \quad \mathbf{h} = \frac{\mathbf{H}_0}{H_0}. \end{aligned}\right\} \tag{16}$$

The boundary conditions satisfied by the fields of the ion-acoustic and high-frequency waves on the plasma–vacuum interface are

$$\begin{gathered} (\varphi^p - \varphi^v)|_{x=0,2d} = 0, \\ \left(\frac{\omega_{pi}^2}{\omega_{Hi}^2}\frac{\partial \varphi^p}{\partial x} - \frac{\partial \varphi^v}{\partial x}\right)\Big|_{x=0,2d} = -\frac{2\pi e n_0}{\omega \Omega}\sum_n (v_{nx} \nabla v^*_{n-1} + v^*_{n-1x} \nabla \mathbf{v}_n)|_{x=0,2d}, \\ (\mathbf{E}^p_{n\tau} - \mathbf{E}^v_{n\tau})|_{x=0,2d} = 0, \\ (\varepsilon_{11} E^p_{nx} + \varepsilon_{12} E^p_{ny} - E^v_{nx})|_{x=0,2d} = \frac{2\pi e n_0}{\Omega_n \omega}(v_{n-1x} \nabla \mathbf{v}_\omega + v_{n+1x} \nabla \mathbf{v}^*_\omega)|_{x=0,2d}. \end{gathered} \tag{17}$$

If longitudinal high-frequency waves are excited, we use the additional boundary condition $v_{nx}|_{x=0,2d} = 0$.

Let us consider the generation of scattered waves when they undergo total internal reflection from the plasma ($\xi_{nx}^2, \varkappa_{nx}^2 < 0$). If the electric field of the probing wave is parallel to the external constant magnetic field, the amplitudes of the waves radiated into the vacuum are

$$\mathcal{E}_n = \frac{2k_{nx}}{k_{nx} + \xi_{nx}} \mathcal{E}_0 \left[-\frac{e\varphi_0 \omega_{pe}^2}{4m_e u^2 c^2 \xi(k + \xi)}\right]^{|n|}. \tag{18}$$

If extraordinary high-frequency waves are excited in the plasma, the radiation at the combination frequencies into the vacuum is amplified when the frequency of the probing signal approaches the hybrid frequency, i.e., $\Omega \gtrsim (\omega_{He}^2 + \omega_{pe}^2)^{1/2} - \omega_g$,

$$\mathcal{E}_n \approx i2\sqrt{2}\,\frac{\omega_g \sqrt{\omega_g(\Omega - \omega_g)}}{\omega_{He}\omega_{pe}}\left[-\frac{\sqrt{2}\, e\varphi_0 (\omega_g^2 + \omega_{He}^2)\,\omega_{pe} k}{16 m_e u^2 \omega_g^2 \sqrt{\omega_g(\Omega - \omega_g)}\, q_x}\right]^{|n|} \frac{\mathcal{E}_0}{n!}. \tag{19}$$

If high-frequency waves propagate in the plasma and are weakly reflected from the plasma–vacuum interface ($R_n \ll 1$ for $\Omega_n \gg \omega_{pe}$ for ordinary waves and for $\Omega_n \approx \omega_{pe}$ for extraordinary waves) there is a resonant interaction between the high-frequency wave and the ion-acoustic wave [$\Delta_{1,2}(n, n-1) \approx \pm q_x \ll u_{nx}$], which changes their amplitudes in accordance with (4). For ordinary waves, the coupling coefficient V_{AA} and the boundary values of the scattered waves, $A_n(0)$, are the same as for an isotropic plasma. The coupling coefficient V_{bA} is

$$V_{bA} = -\frac{e\omega_{He}\omega_{Hi}}{2m_e q_x u^2 \Omega^2}. \tag{20}$$

For extraordinary high-frequency waves the coupling coefficients and boundary values of the amplitudes are

$$V^e_{AA} = \frac{e\omega_{pe}^2 q_z^2}{m_e u^2 \omega_{He} \varkappa}, \quad V^e_{bA} = \frac{e\omega_g^2}{m_i \omega \Omega}, \tag{21}$$

$$\left.\begin{aligned} &A^e_n(0) = \mathcal{E}_0\left[\frac{e\varphi_0}{8m_e u^2}F(\Omega)\right]^{|n|}\left(\frac{\Omega^2 - \omega_{He}^2}{\Omega^2 - \omega_g^2}\right)^{1/2}, \\ &F(\Omega) = \frac{\omega_{pe}^2[\Omega^4 - \Omega^2(3\omega_{He}^2 + \omega_{pe}^2) + \omega_{He}^2\omega_{pe}^2]}{\Omega^2(\Omega^2 - \omega_g^2)^2}. \end{aligned}\right\} \tag{22}$$

From the boundary conditions (17) we find the amplitudes of scattered waves transmitted through the layer into the vacuum. For ordinary waves

$$\mathcal{E}'_n = \frac{2\xi_{nx}}{\xi_{nx} + k_{nx}} e^{i2d(\xi_{nx} - k_{nx})} \sum_{m=-\infty}^{\infty} A_m(0)\, i^{n-m} J_{n-m}(\chi d), \tag{23}$$

where

$$\chi = \frac{1}{8}\left(\frac{e\mathcal{E}_0}{m_e \Omega u}\right)^2 \frac{e\varphi_0 \omega_{pe}^4 \omega_{He} \omega_{Hi}}{m_e u^2 \Omega^4 u^2 q_x^2}\,\xi.$$

For extraordinary waves

$$\mathcal{E}_n'^e = -\frac{\varkappa_{nx}}{k_{nx}+\varkappa_{nx}} e^{i2(\varkappa k_x - k_x)d} \sum_{k=0}^{|n|} \sum_{m=-\infty}^{\infty} \times \left(i \frac{e\varphi_0 \omega_{pi}}{4m_e u c \omega_{He}} \right)^{|n|-k} A_m(0)\, J_{k-m}(\chi^e d), \qquad (24)$$

where

$$\chi^e = \frac{1}{2}\left(\frac{e\mathcal{E}_0}{m_e u \Omega}\right) \frac{e\varphi_0 q_z \Omega \omega_{pi} (\omega_{pe}^2 + \omega_{He}^2) q_e}{m_e u^2 \varkappa \omega \omega_{He}^4} F(\Omega).$$

If χ^d, $\chi^{ed} < 1$ and $\varkappa_{nx}$, $\xi_{nx} \simeq k_{nx}$, the expressions (23) and (24) simplify and reduce to the form (14).

I wish to thank A. S. Bakai and A. N. Kondratenko for suggesting the topic and for helpful discussion.

Electric field and plasma structure near a large charged body

L. A. Malyavin and A. M. Moskalenko

Institute of Terrestrial Magnetism, the Ionosphere, and Radio Propagation,
Academy of Sciences of the USSR, Moscow

(Submitted April 10, 1973; resubmitted August 16, 1973)
Zh. Tekh. Fiz., 44, 311-317 (February 1974)

The perturbations of a weakly ionized plasma in the neighborhood of a charged spherical body are discussed. The dimensions of the body are assumed to be large in comparison with the Debye radius of the unperturbed plasma. The distribution of the electric potential and the electron and ion densities are determined for various potentials on the body. The intensity of the electric field is determined. The total electron and ion currents to the surface of the body are calculated.

INTRODUCTION

The study of the electric field and the charged-particle density distribution in the neighborhood of a body in a weakly ionized plasma is of considerable interest in problems connected with the direct measurement of electric fields from a high-altitude, constant-level, drifting balloon. Much the same problem arises also in the probe measurements widely used in plasmas. The theoretical study of this subject is therefore the concern of a considerable amount of work (for example, see ref. 1 and the references therein).

However, because of the mathematical difficulties encountered in reaching a solution, the complete equation system is solved numerically in most papers. One can point out refs. 2 and 3, in which the problem of a large spherical body is solved by separation of the perturbed zone in its neighborhood into a double layer and a neutral region.

In the present paper, this separation for a large sphere is carried out more rigorously and greater attention is devoted to a study of the limiting cases of high and low potential on the body.

FORMULATION OF THE PROBLEM

We consider a completely absorbing, spherical body in a weakly ionized plasma. We assume the dimension of the body R_0 is much greater than the Debye radius of the unperturbed plasma D,

$$R_0 \gg D,\ D=\left(\frac{T_e}{4\pi e^2 N_0}\right)^{1/2}.$$

Here, T_e is the electron temperature in energy units, e is the charge on the ions (the electron charge is $-e$), and N_0 is the unperturbed electron (and ion) density.

The mean free path of plasma particles is assumed to be much smaller than the characteristic dimensions of the problem.

The electron density N_e, the ion density N_i, and the electric potential φ are determined by the steady-state continuity equations and the Poisson equation:

$$\left.\begin{aligned} &\operatorname{div}\mathbf{j}_e=0,\quad \operatorname{div}\mathbf{j}_i=0,\\ &\Delta\varphi=-4\pi e(N_i-N_e). \end{aligned}\right\} \qquad (1)$$

Here, j_e and j_i are the electron and ion current densities, which are[4]

$$\mathbf{j}_e=-D_e\nabla N_e+\frac{\sigma_e}{e}\nabla\varphi,$$

$$\mathbf{j}_i=-D_i\nabla N_i-\frac{\sigma_i}{e}\nabla\varphi,$$

where D_e, D_i and σ_e, σ_i are respectively the diffusion and conductivity coefficients for electrons and ions. In the case of a weakly ionized plasma these are connected by the Einstein relations:

$$\sigma_e=\frac{e^2N_e}{T_e}D_e,\quad \sigma_i=\frac{e^2N_i}{T_i}D_i.$$

Here, T_i is the ion temperature in energy units.

We take into account the spherical symmetry of the problem and convert to the dimensionless variables

$$\xi=\frac{r}{R_0},\ n_e=\frac{N_e}{N_0},\ n_i=\frac{N_i}{N_0},\ \varphi^*=\frac{e\varphi}{T_e},$$
$$I_e^*=\frac{I_e}{I_{e0}},\ I_i^*=\frac{I_i}{I_{i0}};\ I_{e0}=4\pi R_0N_0D_e,\ I_{i0}=4\pi R_0N_0D_i,$$

where r is the distance from the center of the sphere, and I_e and I_i are the total electron and ion currents at the surface of the body.

After a single integration, Eq. (1) takes the form[5]

$$\left.\begin{aligned} &\frac{dn_e}{d\xi}-n_e\frac{d\varphi^*}{d\xi}=\frac{I_e^*}{\xi^2},\\ &\frac{dn_i}{d\xi}+\beta n_i\frac{d\varphi^*}{d\xi}=\frac{I_i^*}{\xi^2},\\ &\varepsilon\frac{1}{\xi^2}\frac{d}{d\xi}\left(\xi^2\frac{d\varphi^*}{d\xi}\right)=n_e-n_i;\ \beta=\frac{T_e}{T_i}=O(1),\ \ \varepsilon=\left(\frac{D}{R_0}\right)^2\ll 1, \end{aligned}\right\} \qquad (2)$$

where O is a symbol for order of magnitude. The boundary conditions are: $\varphi^*=\varphi_0^*$, $n_e=n_i=0$ for $\xi=1$, and $\varphi^*=0$, $n_e=n_i=1$ for $\xi\to\infty$.

We assume for definiteness that the body is charged positively ($\varphi_0^*>0$) so that the attracted particles are electrons and the repelled particles are ions.

NEUTRAL REGION

Setting $n_e(\xi)=n_i(\xi)=n_q(\xi)$, $\varphi^*(\xi)=\varphi_q^*(\xi)$, and solving Eqs. (2), we obtain for the neutral region

$$\left.\begin{aligned} &n_q(\xi)=1-\frac{A}{\xi},\\ &\varphi_q^*(\xi)=B\ln\left(1-\frac{A}{\xi}\right). \end{aligned}\right\} \qquad (3)$$

Here and in the following we have

$$A = \frac{\beta I_e^* + I_i^*}{1+\beta}, \quad B = -\frac{I_e^* - I_i^*}{\beta I_e^* + I_i^*}.$$

The boundary conditions at infinity are taken into account in Eqs. (3).

The neutral solution (3) is the zeroth approximation to the asymptotic expansion of the perturbation solution of the system (2) in the form of a series in powers of the perturbation parameter ε. More precisely, if we seek a solution of the system (2) in the form

$$n_e = n_e^{(0)} + \varepsilon n_e^{(1)} + \ldots, \tag{4}$$

etc., then $n_e^{(0)} = n_i^{(0)} = n_q$, $\varphi^{*(0)} = \varphi_q^*$.

Near the point $\xi = \xi_{cr} \equiv A$, the solution of system (2) in the form of a series in powers of ε can be represented in the following manner:

$$\left.\begin{aligned}
n_e &= \left(1 - \frac{A}{\xi}\right)\left[1 + \varepsilon \frac{Q_e}{(\xi - A)^3} + \cdots\right],\\
n_i &= \left(1 - \frac{A}{\xi}\right)\left[1 + \varepsilon \frac{Q_i}{(\xi - A)^3} + \cdots\right],\\
\varphi^* &= B \ln\left(1 - \frac{A}{\xi}\right)\left[1 + \varepsilon \frac{P}{(\xi - A)^3 \ln\left(1 - \frac{A}{\xi}\right)} + \cdots\right];\\
Q_e &= \frac{AB}{(1+\beta)}\left(-1 + \frac{\beta B}{2}\right), \quad Q_i = \frac{\beta AB}{(1+\beta)}\left(1 + \frac{B}{2}\right),\\
P &= \frac{A}{3(1+\beta)}\left[-2 - (1-\beta)B + 0.5\beta B^2\right].
\end{aligned}\right\} \tag{5}$$

The pertubation solution (5) has a singularity at the critical point $\xi_{cr} \equiv A$, where the assumption about the smallness of the perturbation breaks down and the solution loses meaning. The solution (5) has a singularity of the form ε/x^3, where x is the distance from the critical point. Consequently, the region in which Eq. (5) is invalid is a neighborhood of the point ξ_{cr} of the order of $\varepsilon^{1/3}$.

DOUBLE LAYER

We introduce new independent and dependent variables

$$x = \frac{\xi - A}{\varepsilon^{1/3}}, \quad H_e = \frac{n_e}{\varepsilon^{1/3}}, \quad H_i = \frac{n_i}{\varepsilon^{1/3}},$$

which are of the order of unity in a neighborhood of the point $\xi_{cr} \equiv A$ of the order[6] of $\varepsilon^{1/3}$.

In the new variables, the system (2) becomes

$$\left.\begin{aligned}
\frac{dH_e}{dx} - H_e \frac{d\varphi^*}{dx} &= \frac{I_e^*}{(A + \varepsilon^{1/3}x)^2},\\
\frac{dH_i}{dx} + \beta H_i \frac{d\varphi^*}{dx} &= \frac{I_i^*}{(A + \varepsilon^{1/3}x)^2},\\
\frac{d^2\varphi^*}{dx^2} + \frac{2\varepsilon^{1/3}}{A + \varepsilon^{1/3}x}\frac{d\varphi^*}{dx} &= H_e - H_i.
\end{aligned}\right\} \tag{6}$$

The form of the equation system (6) suggests the following form for the inner expansions:

$$H_e = H_e^{(0)} + \varepsilon^{1/3} H_e^{(1)} + \ldots, \text{ etc.}$$

We substitute these expressions in Eqs. (6). We then obtain a system of equations for the functions $H_e^{(0)}$, $H_i^{(0)}$, and $\varphi^{*(0)}$. For convenience, we transform to the variable $t = x + (A-1)/\varepsilon^{1/3} = (\xi - 1)/\varepsilon^{1/3}$. We then have

$$\left.\begin{aligned}
\frac{dH_e}{dt} - H_e \frac{d\varphi^*}{dt} &= \frac{I_e^*}{A^2},\\
\frac{dH_i}{dt} + \beta H_i \frac{d\varphi^*}{dt} &= \frac{I_i^*}{A^2},\\
\frac{d^2\varphi^*}{dt^2} &= H_e - H_i.
\end{aligned}\right\} \tag{7}$$

For brevity, we omit the index (0) here and in the following.

The inner boundary conditions for the system (7) remain as before ($\varphi^* = \varphi_0^*$, $H_e = H_i = 0$, when $t = 0$). As outer boundary conditions, we require that when $x = 1$ the solution of equation system (7) be equal to the leading terms of the inner expansion of the neutral solution. We than obtain $\varphi^* = \varphi_1^* \equiv B\ln(\varepsilon^{1/3}/A)$, $H_e = H_i = 1/A$ when $t = t_1 \equiv 1 + (A-1)/\varepsilon^{1/3}$.

Solutions for the first two equations in (7) including the boundary conditions when $t = t_1$ are

$$\left.\begin{aligned}
H_e(t) &= \frac{1}{A} e^{(\varphi^* - \varphi_1^*)} - \frac{I_e^*}{A^2} e^{\varphi^*} \int_t^{t_1} e^{-\varphi^*(t')} dt',\\
H_i(t) &= \frac{1}{A} e^{-\beta(\varphi^* - \varphi_1^*)} - \frac{I_i^*}{A^2} e^{-\beta\varphi^*} \int_t^{t_1} e^{\beta\varphi^*(t')} dt'.
\end{aligned}\right\} \tag{8}$$

Using the boundary conditions for the particle densities at the surface of the body, we obtain a system of two transcendental equations for the determination of I_e^* and I_i^*:

$$\left.\begin{aligned}
e^{-\varphi_1^*} - \frac{I_e^*}{A} \int_0^{t_1} e^{-\varphi^*(t)} dt &= 0,\\
e^{\beta\varphi_1^*} - \frac{I_i^*}{A} \int_0^{t_1} e^{\beta\varphi^*(t)} dt &= 0.
\end{aligned}\right\} \tag{9}$$

LOW AND HIGH POTENTIAL ON THE BODY

For low values of the potential on the body, $\varphi_0^* \ll 1$, the potential will also be low everywhere in its neighborhood, i.e., $\varphi^* \ll 1$. Then the exponentials in Eqs. (9) can be expanded in powers of φ^* and limited to linear terms; the electron current I_e^* and the ion current I_i^* then can be represented by

$$I_e^* = 1 + \delta, \quad I_i^* = 1 - \gamma,$$

where $\delta \ll 1$ and $\gamma \ll 1$. In the linear approximation relative to δ and γ we have

$$A = 1 + \frac{\beta\delta - \gamma}{1+\beta}, \quad \varphi_1^* = -\frac{\delta + \gamma}{1+\beta} \ln \varepsilon^{1/3}, \quad t_1 = 1 + \frac{\beta\delta - \gamma}{(1+\beta)\varepsilon^{1/3}}. \tag{10}$$

Substituting these expressions in Eqs. (9) and equating terms with $\varepsilon^{-1/3}$ and $\ln\varepsilon^{1/3}$ to zero, we obtain

$$\beta\delta = \gamma, \quad \varphi_1^* = \int_0^{t_1} \varphi^*(t)\, dt. \tag{11}$$

In this case, $A = t_1 = 1$. Remembering the monotonicity of the function φ^*, we have from the second of Eqs. (11)

$$\varphi_1^* = \varphi^*(t) = \varphi_0^* \tag{12}$$

for $0 \leq t \leq 1$.

Thus for φ_0^*, the field potential at the external boundary of the double layer is φ_0^*, i.e., in a linear approximation relative to φ^*, a double layer does not exist around a spherical absorbing body.

From the second equation in (10) and the first equations in (11) and (12), we obtain

$$I_e^* = 1 + \frac{\varphi_0^*}{\ln \frac{1}{\varepsilon^{1/3}}},\ , I_i^* = 1 - \frac{\beta\varphi_0^*}{\ln \frac{1}{\varepsilon^{1/3}}}.$$

For the neutral region $\xi \geq 1 + \varepsilon^{1/3}$, we have in accordance with Eqs. (3)

$$n_q = 1 - \frac{1}{\xi},\ \varphi_q^* = \frac{\varphi_0^*}{\ln \varepsilon^{1/3}} \ln\left(1 - \frac{1}{\xi}\right), \tag{13}$$

with the first expression for particle density valid for $\xi \geq 1$.

Note that the boundary conditions $n_i = n_e = 0$ for particle densities at the surface of the absorbing body indicate that the plasma in the neighborhood of such a body is stripped of charged particles, which is particularly apparent from the first equation in (13). This leads to an increase in the thickness of the double layer in comparison with the case of a low-density plasma. In fact, when $\varepsilon \to 0$, the thickness of the double layer is $l \sim \varepsilon^{1/3} \gg l_1 \sim \varepsilon^{1/2}$, where l_1 is the thickness of the double layer around a large body in a low-density plasma.[7]

For high potentials on the body, $\varphi_0^* \gg 1$, the ion current at the body is close to zero,

$$A = \frac{\beta}{1+\beta} I_e^*,\ B = -\frac{1}{\beta}.$$

The ion distribution in the double layer is described by the Boltzmann equation

$$H_i(t) = \frac{1}{A} e^{-\beta(\varphi^* - \varphi_1^*)},$$

which follows from the second equation in (8) when $I_i^* = 0$.

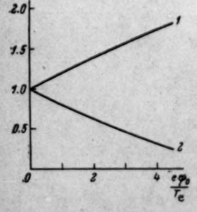

Fig. 1. Dependence of total electron current I_e^* (attracted particles) and total ion current I_i^* (repelled particles) on the potential of the body for $R_0/D = 100$ and $\beta = 1$. 1) I_e/I_{e_0}; 2) I_i/I_{i_0}.

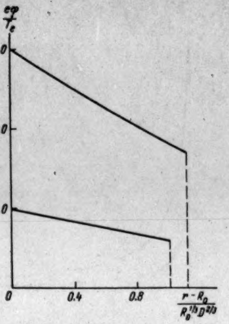

Fig. 2. Variation of the potential field in the double layer around the surface of a large body ($R_0/D = 100$) for $\beta = 1$ and various values φ_0^*.

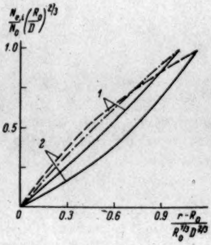

Fig. 3. Density of electrons (attracted particles) and of ions (repelled particles) in the double layer around the surface of a large body ($R_0/D = 100$) for $\beta = 1$ and various values of φ_0^*: 1) 1; 2) 3.

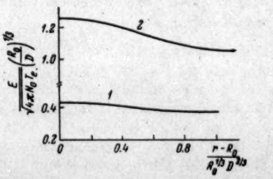

Fig. 4. Variation of electric field in the double layer around the surface of a large body ($R_0/D = 100$) for $\beta = 1$ and various values of φ_0^* φ_0^*: 1) 1; 2) 3.

We estimate the electron current at the body. For $\varphi_0^* \gg 1$, the potential of the field in the double layer is sharply reduced from the value φ_0^* at the surface of the body to some other value φ_1^*. Assuming that for $0 \leq t \leq t_1$

$$\varphi^*(t) = \varphi_0^* - \frac{\varphi_0^* - \varphi_1^*}{t_1} t,$$

and substituting this function in the first equation in (9), we obtain

$$I_e^* = \frac{1+\beta}{\beta} + O(\varepsilon^{1/3}\varphi_0^*).$$

Furthermore,

$$A = 1 + O(\varepsilon^{1/3}\varphi_0^*),\ \ \varphi_1^* = \frac{1}{\beta} \ln \frac{1}{\varepsilon^{1/3}},\ \ t_1 = O(\varphi_0^*).$$

It then follows that the thickness of the double layer, which is proportional to t_1, increases as φ_0^* increases.

Note that we assume here the thickness of the double layer is small in comparison with the dimension of the body, i.e., $l = \varepsilon^{1/3} t_1 \ll 1$. This is valid only when there is

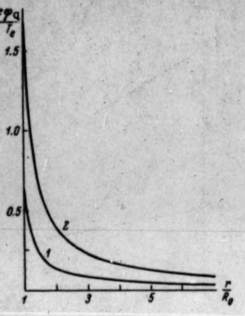

Fig. 5. Variation of potential in neutral region in the neighborhood of a body ($R_0/D = 100$) for $\beta = 1$ and various values of φ_0^*. φ_0^*: 1) 1; 2) 3.

a limit on the magnitude of the potential on the body:

$$\varphi_0^* \ll \frac{1}{\varepsilon^{1/3}} = \left(\frac{R_0}{D}\right)^{2/3}.$$

RESULTS OF CALCULATIONS

Equation (7), including the conditions (9), is solved numerically by linearization[8] for arbitrary values of the potential φ_0^* on the body. Results of the calculations for $R_0/D = 100$ and $\beta = T_e/T_i = 1$ are shown in Figs. 1-5.

Figure 1 shows the dependence of the electron currents I_e^* (attracted particles) and of the ion current I_i^* (repelled particles) on the potential $\varphi_0^* = e\varphi_0/T_e$ of the body. The curves in Fig. 1 are in good agreement with corresponding curves published previously.[1,3,9]

Using the resultant value of I_e^* and I_i^*, we find that the quantities $Q_e \ll 1$ and $|Q_i| \ll 1$ when $\varphi_0^* < 4$. Consequently, the second term in the square brackets in Eqs. (5) makes only a small correction to the neutral solution for these values of φ_0^* and for $\xi \geq A + \varepsilon^{1/3}$. Thus the neutral solution (3) is valid for $A + {}^{1/3} \leq \xi \leq \infty$, and for $1 \leq \xi \leq A + \varepsilon^{1/3}$ the double-layer solution, which is determined by the equation system (7), where the same assumption was made, is valid.

Figure 2 shows the behavior of the potential $\varphi^* = e\varphi/T_e$ in the double layer around the surface of the body for $\varphi_0^* = 1$ and 3.

The distribution of electron density $H_e = (N_e/N_0) \cdot (R_0/D)^{2/3}$ and of ion density $H_i = (N_i/N_0)(R_0/D)^{2/3}$ in the double layer is shown in Fig. 3 for various potentials on the body.

The variation of electric field $E^* = -d\varphi^*/dt = [E/(4\pi N_0 T_e)^{1/2}](R_0/D)^{1/3}$, where $E = -d\varphi/dr$ in the double layer as a function of distance from the surface of the body, is shown in Fig. 4 for $\varphi_0^* = 1$ and 3. For $\varphi_0^* \gg 1$, the electric field at the surface of the body itself is $E_0^* = 2$.

Using the values obtained for the electron current I_e^* and the ion current I_i^* at the surface of the body, we now determine from Eqs. (3) the particle distribution and the behavior of the electric potential in the neutral region. We finally find that for $\varphi_0^* = 1$ and 3 the curve for n_q practically merges with the curve for $\varphi_0^* = 0$, i.e., particle distribution in the neutral region is almost independent of the potential on the body.

Figure 5 shows the dependence of the electric potential $\varphi_q^* = e\varphi_q/T_e$ on distance for $\varphi_0^* = 1$ and 3.

We note in conclusion that this analysis is made under the assumption the mean free paths l_e for electrons and l_i for ions are much smaller than the thickness of the double layer around the surface of the body, i.e.,

$$l_e \ll R_0^{1/3} D^{2/3}, \quad l_i \ll R_0^{1/3} D^{2/3}.$$

The authors are grateful to A. V. Gurevich for discussion and to I. A. Zhulin for his interest.

Production of an ion beam by a magnetic system with opposed fields

V. B. Glasko, A. G. Sveshnikov, and N. N. Semashko

M. V. Lomonosov Moscow State University

(Submitted March 27, 1973; resubmitted August 20, 1973)
Zh. Tekh. Fiz., 44, 318-324 (February 1974)

The effect of variation of parameters of the magnetic system and injection parameters on the production of a beam is analyzed. The investigation is carried out for a system with opposed magnetic fields. The parameters are varied close to their values to ensure "optimum" beam-focusing conditions.

1. In many situations it is necessary to produce focused beams of intermediate-energy ions (10-100 keV) at high currents (tens of amperes). Gas-discharge ion sources with large ion-emitting surfaces are one method of obtaining such beams. The efficiency of this device is determined primarily by the magnetic system, which must provide an arc discharge with the required configuration (since the plasma serves as the ion emitter) and must focus the ion beam (large cross section).

The problem of designing magnetic systems to ensure focusing of a charged-particle beam is usually solved either empirically or by an approximate calculation of the motion of the paraxial beam.[1-4] In the general formulation the problem of determining the magnetic field that will produce a charged-particle beam with given properties is a typical synthesis problem, and is characterized by an instability of the solution against small variations of the "input information" (the given properties of the beam).

We have considered earlier[3] the problem of designing an axially symmetric magnetic field in the region $0 < z < z_{ex}$ and the conditions for injection of beam particles into the $z = 0$ plane, for which, at the exit from the system in the $z = z_{ex}$ plane, the charge-particle beam satisfies definite focusing requirements. We assume that the ion beam consists of separate noninteracting rays whose trajectories depend on the injection conditions. If the magnetic field and the injection conditions can be specified by a finite number of parameters $(p_1, \ldots, p_N)$, the problem of determining the magnetic field and the injection conditions for which the formulated beam has the required properties reduces to the problem of the "quasioptimization" of a certain positive functional $\Phi(p_1, \ldots, p_N)$, whose minimum corresponds to the "optimum" properties of the beam that is formed.

Besides determining the "optimum" conditions of beam focusing there is considerable interest in analyzing the effect on the production of a beam of the variation of parameters of the magnetic system and the injection conditions. This question is considered in the present work for the case of a system with opposed magnetic fields.

2. The magnetic field is produced by a system of four current-carrying coils (Fig. 1). The two central coils (I) with currents flowing in opposition form the principal field (H_I); the external current-carrying coils (II) are magnetic lenses (H_{II}).

This system is intended for a high-current ion source. Near the median surface of the field ($z = 0$) an arc discharge is ignited along radial lines of force, forming a plasma ring. The side surfaces of this ring serve as the ion emitter. Ions are extracted from the plasma across the magnetic lines of force by a strong electric field and are accelerated along the longitudinal (z) axis.

The magnetic field is determined by specifying the longitudinal component of the field H_z as a function of $F(z)$ for a certain value of radial coordinate $\bar{r}$:

$$H_z(r, z) \equiv F(z) = H_I(z) + \alpha H_{II}(z - z_{II}), \tag{1}$$

where the functions $H_I(z)$ and $H_{II}(z)$ approximate the given values of the longitudinal component H_z for the specified radius $\bar{r}$ of the actual magnetic system consisting of two pairs of coils.

The parameter α determines the ratio of the currents in the first and second pairs of coils, and z_{II} is the position of the coils (II) with respect to the $z = 0$ plane. Specifying the magnetic field in the form (I) enables us to represent the magnetic-field components H_z and H_r in the following form over the entire region of motion of the particles:

$$\left.\begin{aligned} H_z &= \sum_{n=1}^{N} d_n \frac{I_0(k_n r)}{I_0(k_n \bar{r})} \sin k_n z, \\ H_r &= -\sum_{n=1}^{N} d_n \frac{I_1(k_n r)}{I_0(k_n \bar{r})} \cos k_n z, \end{aligned}\right\} \tag{2}$$

where $k_n = (n\pi)/L$, d_n is the Fourier coefficient for the field $H_z(\bar{r}, z)$, and L is the period.

Because of the axial symmetry, the vector potential of the magnetic field has the form $\mathbf{A} = \{0, A_\varphi(r, z), 0\}$, and the generalized azimuthal momentum p_φ is a first integral of the equations of motion; $p_\varphi = rv_\varphi + rA_\varphi(r, z) = \text{const}$. Since the magnetic field satisfies the condition $A_\varphi(r, 0) = A_\varphi(r, z_{ex}) = 0$, the particles that emerge from the system (for $z > z_{ex}$) will not have an azimuthal velocity component: $v_\varphi(r, z_{ex}) = 0$ if the injection condition is satisfied: $v_\varphi(r, 0) = 0$. The latter condition is a constraint on the position of the ion-emitting surface in the magnetic field.

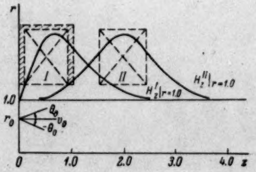

Fig. 1. Diagram of magnetic system. $H_z = 0$ for $z = 6$.

We consider a beam consisting of separate beams of charged particles of specified energy E_0 (total velocity v_0), which are formed under specified initial conditions in the median plane of the field ($z = 0$), radius r_0, and angular spread $\delta\theta_0$ in the (r, z) plane. Thus, the injection parameters $p_1 = r_0$, $p_2 = \theta_0$, $p_3 = v_0$.

The motion of charged particles in the field (2) is investigated by numerical integration of the exact equations of motion.[2] The system is solved in dimensionless (dl) quantities in terms of dimensional (d) quantities as follows:

$$r_{\mathrm{dl}} = \frac{r_{\mathrm{d}}}{R_0},\quad v_{\mathrm{dl}} = \frac{v_{\mathrm{d}}}{v_0},\quad h_{\mathrm{dl}} = \frac{H_{\mathrm{d}}}{H_0},\quad \tau = \omega_{H_0} t. \tag{3}$$

The dimensional constants are related by the condition

$$\frac{eH_0}{mc} = \frac{v_0}{R_0}, \tag{4}$$

i.e., the similitude parameter of the system

$$\chi = \frac{H_0 R_0}{A v_0} = 1.1 \cdot 10^4 \frac{1}{A}\ [\mathrm{G/cm}]. \tag{5}$$

Here, A is the atomic mass unit ($A = 1$ for H_1^+ ions).

Hence, taking R_0, a linear dimension of the system (e.g., the inner radius of the coil) as an independent parameter, we can analyze the system by variation of the parameters that characterize the magnetic field (H_0) and its geometry (K), for various initial conditions of the particle motion (r_0, θ_0). Variation of the parameter H_0 is equivalent to variation of the particle velocity v_0 ($H_0 \sim 1/v_0$) and variation of the parameter K is equivalent to variation of the geometry ($K \equiv \pi R_0/L$); L/R_0 is the ratio between the longitudinal and transverse dimensions of the system.

The particles are injected into the $z = 0$ plane and the trajectories are calculated up to $z_{ex} = 5.9$, where the field H_z is taken equal to zero. The limiting injection radius r_0 is determined by the construction of the ion source, and lies in the range $0.1 < r_0 < 0.8$. The initial velocity v_0 varies from 0.508 to 6.0. The initial ray angle θ_0 for each injection radius is varied in the (r, z) plane from −5° to + 5°; the central ray ($\theta_0 = 0$) is parallel to the z axis.

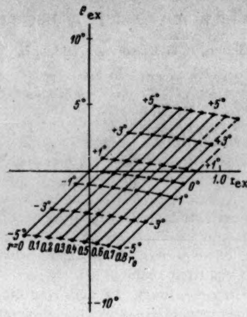

Fig. 2. Phase diagram of beam in exit plane of system ($z_{ex} = 5.9$). Initial conditions: $z = 0$; $0 \le r_{0i} \le 0.8$; $-5° \le \theta_0 \le +5°$; $v_0 = 6.0$.

Results of a numerical integration of the equations of motion are given in Figs. 2 and 5 in the form of phase diagrams of the beams, i.e., the coordinates and angles (r_{ex}, $dr/dz \sim \theta_{ex}$) of the rays in the exit plane ($z = z_{ex}$) are indicated as functions of the initial conditions r_0, θ_0, and v_0. Only the half of the total beam injected into the positive half-plane ($z = 0$, $r > 0$) is represented. Points on the r_{ex}, θ_{ex} diagram in the upper half-plane ($\theta_{ex} > 0$) correspond to diverging rays; those in the lower half-plane ($\theta_{ex} < 0$) correspond to rays that converge to the axis. Points located in the right half-space of the diagram ($r_{ex} > 0$) correspond to rays that do not intersect the z axis, and those in the left half-space ($r_{ex} < 0$) correspond to rays that intersect the z axis in the magnetic-field region ($z < z_{ex}$).

As an illustration Fig. 3 gives the behavior of the rays

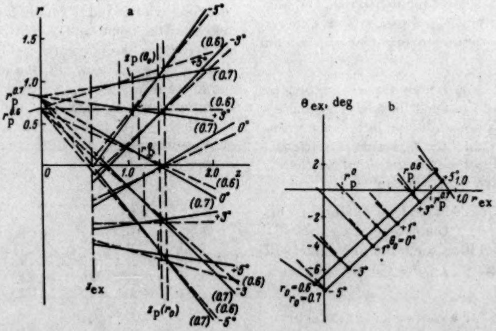

Fig. 3. Trajectories of rays of two beams outside the magnetic field (a) and the corresponding phase diagram in the exit plane $z_{ex} = 5.4$ (b). Initial conditions: $z = 0$, $r_0 = 0.6$ and 0.7, $-5° \le \theta_0 \le +5°$, $v_0 = 3.0$.

outside the magnetic field ($z > z_{ex} = 5.9$), for two beams injected with $z = 0$, $r_0 = 0.6$ and 0.7, $\theta_0 = \pm 5°$ and the corresponding phase diagram (r_{ex}, θ_{ex}) in the z_{ex} plane.

In the absence of beam aberrations the phase lines corresponding to the rays r_{0i} = const are rectilinear and parallel. In this case all the rays of the beam intersect in a single plane $z = z_p(r_{0i})$ at radii $r = r_p(r_{0i})$. The coordinate $r_p(r_{0i})$ is determined by the intersection point corresponding to a line on the phase plane with the abscissa axis. The value of $z_p(r_{0i})$ can be determined from the obvious relation

$$z_p = z_{ex} + (r_p - r_{ex}) \operatorname{ctg} \theta_{ex}. \tag{6}$$

Similarly, the coordinate $r_p(\theta_{0i})$ is determined from the intersection point of the corresponding phase line θ_{0i} = const with the abscissa axis, and the value of $z_p(\theta_{0i})$ from Eq. (6). The deflection of the phase lines r_{0i} = const confirms the existence of aberrations in the initially converging beam and blurring of the focal ring r_p, and violation of the parallelism of the lines characterizes the displacement of the focal plane $r_p(r_{0i})$. The deflection and nonparallelism of the phase lines θ_{0i} = const confirm the existence of aberrations in the initially parallel beam.

In the case being considered (a characteristic example is represented in Fig. 3) the phase lines r_{0i} = const are straight lines but are not parallel. This result indicates the intersection of the rays r_{0i} = const θ_0 = var at definite radii $r_p(r_{0i})$ with formation of a ring in different planes $z_p(r_{0i})$. The deflection and nonparallelism of the phase lines θ_0 = const, r_0 = var also indicate that the rays intersect at different radii $r_p(\theta_{0i})$ in the $z_p(\theta_{0i})$ planes, whose coordinates z_p increase in proportion to the decrease in the initial radius r_{0i}.

Along ray trajectories with specific initial parameters (r_0, θ_0) we can construct a beam distribution over the radius in transverse planes (z = const) under the following assumptions: In the $z = 0$ plane several tubular beams are injected, for which the radius r_0 is much greater than the initial width δr_0 (thus they can be compared with an element of a ribbon beam); the entire beam is confined within the initial angle $\theta_0 = \pm 5°$; the current density distribution as a function of the initial angle of divergence θ_0 is assumed linear. Summing the beams with different initial injection radii we can determine the configuration of the composite beam (Fig. 4).

3. From an analysis of the trajectories of the rays comprising the ion beam, we can draw certain conclusions.

a. For small initial particle velocities ($v_0 < 3$) the ray trajectories intersect the longitudinal z axis in the region of the magnetic field ($z < 5.9$). This corresponds to a short-focus magnetic system, and the initial conditions (r_0, θ_0) have a strong effect on the exit parameters (r_{ex}, θ_{ex}). It is not possible in practice to produce a beam of particles for further transport with a wide range of initial conditions r_0, θ_0.

b. In proportion to the increase of initial velocity v_0($v_0 > 3$) the beam from the refocused source becomes diverging (Fig. 5). Intersection of the central ray ($\theta_0 = 0$) with the z axis is eliminated with increasing v_0, thereby increasing the focal length of the system. A region of large values of v_0($v_0 \simeq 6$) is convenient for transport of the beam for large distances (scale of tens of transverse dimensions of the beam). The initial conditions do not strongly affect the beam configuration. In practice, beams with various injection radii r_0 are superimposed on each other, and their intensities are summed (Fig. 4). This allows us to use as an ion-emitting surface the entire central part of the median surface of the magnetic field ($z = 0$, $0 < r_0 < 0.8$).

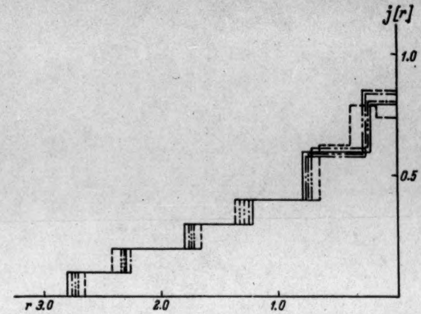

Fig. 4. Beam distribution over radius in $z = 30$ plane for emission of five beams. Initial conditions: $z = 0$; $r_0 = 0.3, 0.4, 0.5, 0.6, 0.7$; $-5° \leq \theta_0 \leq +5°$, $v_0 = 6.0$.

c. The configuration (divergence) of the beam proves to be, as expected, most strongly affected by the initial angular spread of the beam $\delta\theta_0$. A reduction in spread from $\theta_0 = \pm 5°$ to $\theta_0 = \pm 3°$ changes significantly the configuration of the ion beam and its transverse dimensions (Figs. 2, 3, and 5).

d. For production of hydrogen-ion beams containing the two components H_1^+ and H_2^+ there should be no noticeable separation of ions according to mass. This can be concluded from a comparison of the data, e.g., for $v_0 = 4.2$, corresponding to H_1^+ ions, and $v_0 = 6.0$, corresponding to H_2^+ ions.

e. A definite correction to the exit parameters of the beams can be made using a single magnetic lens (the coils

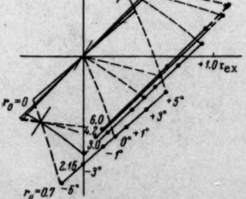

Fig. 5. Phase diagram of beam in exit plane ($z_{ex} = 5.9$) for various velocities. v_0: 2.15, 3.0, 4.2, 6.0 Initial conditions: $z = 0$, $0 \leq r_0 \leq 0.7$, $-5° \leq \theta_0 \leq +5°$.

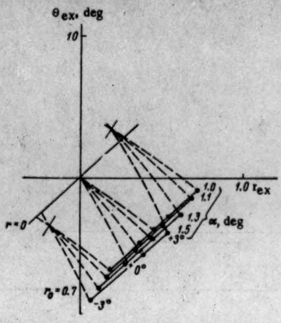

Fig. 6. Phase diagram of beam in exit plane $z_{ex} = 5.9$ with variation of parameter α (current in lens II). The position of the lens $z_l = 2$. Only the phase lines corresponding to rays $r_0 = 0.7$ are plotted.

II). As is to be expected in favorable cases, when $v_0 > 3$ for lens fields comparable in magnitude with the principal fields the exit beam can be finely adjusted without varying the principal field (Fig. 6). This is convenient since it does not lead to a change in the operation regime of the ion source. The position of the lens with respect to the median surface (z_l) does not play a significant role in the production of the beam (Fig. 7) and can be compensated by the magnitude of the lens field.

f. Analysis of the r_{ex}, θ_{ex} phase diagrams shows that the effect of a variation of parameters of the magnetic system on the production of the exit beam can be estimated approximately using elementary relations of geometrical optics. Actually, the beam aberrations are small and do not play a decisive role in the production of the beam. Only an insignificant nonparallelism is observed in the phase lines r_{0i} = const and the observed deflection in the lines θ_{0i} = const is small (Fig. 2). This indicates that the radius of the focal ring (r_f) and the position of the focal plane (z_f) are functions of the initial radius r_0 (Fig. 3).

4. The effect of the second parameter of the system $k = \pi/(L/R_0)$ characterizing the distance between the coils (or the maxima of the field on the z axis) is investigated in a model magnetic field, which is expressed by a single harmonic of the field (2):

$$\left.\begin{aligned} h_r &= I_1(kr)\cos kz,\\ h_z &= -I_0(kr)\sin kz.\end{aligned}\right\} \qquad (7)$$

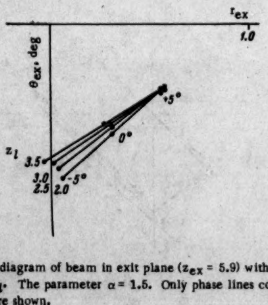

Fig. 7. Phase diagram of beam in exit plane ($z_{ex} = 5.9$) with variation of lens position z_l. The parameter $\alpha = 1.5$. Only phase lines corresponding to rays $r_0 = 0.7$ are shown.

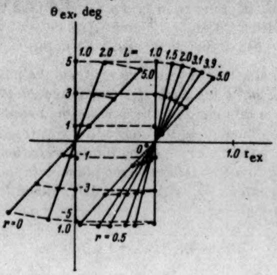

Fig. 8. Phase diagram of beam in exit plane ($z_{ex} = L$) for variation of geometrical parameter of system L/R_0.

This allows us to analyze comparatively simply the relative effect of the geometrical parameter of the system on the configuration of the exit particle beam for various injection conditions (r_0, θ_0) and initial velocities v_0.

In the field model that we have assumed the distance between the coils, where $h_z|_{r=0} = 1$, proves to be equal to L/R_0 (in dimensionless units). The exit plane, in which the coordinates and angles r_{ex}, θ_{ex} are calculated, is found at a distance L/R_0 from the median surface $z_{ex} = L$. The equations of motion are integrated for $0 < z < L$, $0 < r < R_0$. The injection parameters remain as previously. The geometrical parameter L/R_0 varies from 1 to 5: from a system "compressed" along the z axis to a "stretched" system. For comparison we note that in the first case the magnetic system corresponds approximately to the parameter $L/R_0 \approx 2$.

The calculated results are represented in Fig. 8 in the form of a phase diagram in the position of the exit points (r_{ex}, θ_{ex}) in the "exit" plane ($z_{ex} = L/R_0$) as a function of the initial conditions (r_0, θ_0) for initial velocity $v_0 = 0.508$. Calculations have also been carried out for other values of the velocity v_0. The qualitative picture remains unchanged.

Analysis of the phase diagrams of the beam shows that for variation of parameter L/R_0 there is a definite change in the optical force of the magnetic system. In proportion to the increase in parameter L/R_0 (expansion of the system) the optical force increases somewhat (the focal length decreases). In the large this fact leads to the fact that for expansion of the system with the other parameters remaining fixed, we require a decrease in the magnetic field H_0 (or velocity v_0) to obtain a similar beam configuration. A change in the geometrical factor within certain limits does not change the qualitative nature of the production of an ion beam.

(Submitted April 10, 1973; resubmitted August 16, 1973)
Zh. Tekh. Fiz., 44, 325-332 (February 1974)

Perturbations caused by a spherical body with a high potential in weakly ionized plasma are discussed. The cases in which the body is much larger and much smaller than the Debye radius of the unperturbed plasma are analyzed in detail. The distributions of electric potential, electron density, and ion density near the body have been determined. Total particle fluxes to the body surface are calculated.

FORMULATION OF THE PROBLEM

Large body. Consider a spherical body in a weakly ionized plasma. Assume that the body is totally absorbing, i.e., all electrons are absorbed and ions neutralized on reaching the body surface. Let the surface of the body be at the potential φ_0.

The mean free path of the plasma particles is assumed to be much smaller than the characteristic dimensions of the problem.

The electron density N_e, the ion density N_i, and the electric potential φ are described by the steady-state macroscopic equations of continuity and by the Poisson equation:

$$\left.\begin{aligned} &\operatorname{div}\mathbf{j}_e=0, \quad \operatorname{div}\mathbf{j}_i=0,\\ &\Delta\varphi=-4\pi e(N_i-N_e). \end{aligned}\right\} \tag{1}$$

Here e is the ion charge (the electron charge is $-e$), and $\mathbf{j}_e$ and $\mathbf{j}_i$ are the electron and ion flux densities, given by[1]

$$\mathbf{j}_e=-D_e\nabla N_e+\frac{\sigma_e}{e}\nabla\varphi,$$

$$\mathbf{j}_i=-D_i\nabla N_i-\frac{\sigma_i}{e}\nabla\varphi,$$

where D_e, D_i and σ_e, σ_i are respectively the diffusion and conductivity for electrons and ions. In case of a weakly ionized plasma these are related by the Einstein equation:

$$\sigma_e=\frac{e^2N_e}{T_e}D_e, \quad \sigma_i=\frac{e^2N_i}{T_i}D_i.$$

Here T_e and T_i are the electron and ion temperature in energy units.

To be definite, assume that the body is positively charged ($\varphi_0 > 0$) so that electrons are attracted and ions repulsed.

Let us first consider a large body, i.e., a body whose radius R_0 is much greater than the Debye radius of the unperturbed plasma D:

$$R_0\gg D, \quad D=\left(\frac{T_e}{4\pi e^2N_0}\right)^{1/2},$$

where N_0 is the unperturbed electron (and ion) density.

In a former work[2] the present authors proved that for

$$\varphi_0\ll\frac{T_e}{e}\left(\frac{R_0}{D}\right)^{3/2}$$

the charge of the body is screened in a thin double layer near its surface. The layer thickness is $\sim R_0^{1/3}D^{2/3}$. The thickness of this layer increases with the body potential.

Consider now the case of very high body potentials, when

$$\varphi_0\gg\frac{T_e}{e}\left(\frac{R_0}{D}\right)^{3/2}.$$

With such potentials, the perturbed domain near the body consists of region of neutrality, the double layer, the space charge region, and a diffusion layer. The variation of the relative electron density N_e/N_0 and ion density N_i/N_0 is shown in Fig. 1, in which r denotes the distance from the sphere center.

In the equations of neutrality and the double layer, the absorbing layer is a sphere of radius R_c, where R_c is the radius of the space charge region. We introduce the dimensionless variables

$$\xi=\frac{r}{R_c}, \quad n_e=\frac{N_e}{N_0}, \quad n_i=\frac{N_i}{N_0}, \quad \varphi^*=\frac{e\varphi}{T_e};$$

$$I_{ee}^*=\frac{I_e}{I_{e0}}\xi_0, \quad I_{e0}=4\pi R_0N_0D_e, \quad \xi_0=\frac{R_0}{R_c},$$

where I_e is the total electron flux to the surface of the body.

After one integration, (1) becomes

$$\left.\begin{aligned} &\frac{dn_e}{d\xi}-n_e\frac{d\varphi^*}{d\xi}=\frac{I_{ee}^*}{\xi^2},\\ &\frac{dn_i}{d\xi}+\beta n_i\frac{d\varphi^*}{d\xi}=0,\\ &\varepsilon\Delta\varphi^*=n_e-n_i; \quad \varepsilon=\left(\frac{D}{R_c}\right)^2\ll1, \quad \beta=\frac{T_e}{T_i}=O(1). \end{aligned}\right\} \tag{2}$$

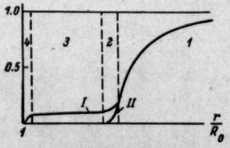

Fig. 1. Variation of the density of electrons (attracted particles) N_e and ions (repulsed particles) N_i in the vicinity of a highly charged body. 1) Neutral domain; 2) double layer; 3) space-charge region; 4) diffusion layer; I) N_e/N_0; II) N_i/N_0.

This takes account of the fact that at high positive potentials of the body, the ion flux to the surface $I_i = 0$. The boundary conditions are $\varphi^* = \varphi_0$, $n_e = n_i = 0$ for $\xi = \xi_0$, and $\varphi^* = 0$, $n_e = n_i = 1$ for $\xi \to \infty$.

Following ref. 2, let us consider the neutral region and the double layer.

Neutral region. In this region ($A + \varepsilon^{1/3} \le \xi < \infty$) we have

$$n_2(\xi) = 1 - \frac{A}{\xi}, \quad \varphi_2^*(\xi) = B \ln\left(1 - \frac{A}{\xi}\right),$$

where

$$A = \frac{\beta}{1+\beta} I_{ec}^*, \quad B = -\frac{1}{\beta}.$$

The particle density and the electric field potential obey the Boltzmann equation

$$n_2(\xi) = \exp\left[-\beta\varphi_2^*(\xi)\right],$$

as follows from the second equation in the system (2).

Double layer ($1 \le \xi \le A + \varepsilon^{1/3}$). Let us introduce the new independent and dependent variables

$$x = \frac{\xi - A}{\varepsilon^{1/3}}, \quad H_e = \frac{n_e}{\varepsilon^{1/3}}, \quad H_i = \frac{n_i}{\varepsilon^{1/3}},$$

which in the neighborhood of the critical point $\xi_{cr} = A$ of the order $\varepsilon^{1/3}$ have the order of unity.

To within terms of the order $\varepsilon^{1/3}$ and using the new variables, (2) becomes

$$\left.\begin{aligned} &\frac{dH_e}{dx} - H_e \frac{d\varphi^*}{dx} = \frac{I_{ec}^*}{A^2}, \\ &\frac{dH_i}{dx} + \beta H_i \frac{d\varphi^*}{dx} = 0, \\ &\frac{d^2\varphi^*}{dx^2} = H_e - H_i. \end{aligned}\right\} \qquad (3)$$

For the sake of convenience, let us put $t = x + (A - 1)/\varepsilon^{1/3} = (\xi - 1)/\varepsilon^{1/3}$. Then, in place of (3) we have

$$\left.\begin{aligned} &\frac{dH_e}{dt} - H_e \frac{d\varphi^*}{dt} = \frac{I_{ec}^*}{A^2}, \\ &\frac{dH_i}{dt} + \beta H_i \frac{d\varphi^*}{dt} = 0, \\ &\frac{d^2\varphi^*}{dt^2} = H_e - H_i. \end{aligned}\right\} \qquad (3a)$$

The boundary conditions for (3a) are

$$\varphi^* = \varphi_1^* \equiv B \ln(\varepsilon^{1/3}/A), \; H_e = H_i = 1/A \; \text{for} \; t = t_1 \equiv 1 + (A-1)/\varepsilon^{1/3};$$

$$\varphi^* = \varphi_2^* \gg 1 \; \text{for} \; t = 0.$$

Here φ_2^* is the potential at the inner boundary of the double layer. The case $\varphi_2^* \gg 1$ has been discussed in detail in ref. 2. In particular, the expression derived for I_{ec}^* is

$$I_{ec}^* = \frac{1+\beta}{\beta}.$$

Note that this result derives essentially from the condition A = 1.

As before, the ion distribution in the double layer is described by the Boltzmann equation

$$H_i(t) = \frac{1}{A} e^{-\beta(\varphi^* - \varphi_1^*)}.$$

When $\varphi_2^* \gg 1$, the electric field $E_0^* = -d\varphi^*/dt(0)$ is equal to

$$E_0^* = -C,$$

where C is a constant of the order of unity. If $\beta = 1$ and $R_0/D = 100$, the constant C = 2 (see ref. 2).

Space-charge region ($\xi \le 1$). In the space-charge region we have to solve the system (2). Also, if $\xi < 1$, the field potential φ^* is of the order of φ_0^* and thus $\varphi^* \gg 1$. The density of ions (repulsed particles) n_i at $\varphi^* \gg 1$ is exponentially small and can be neglected. The electron density n_e in the double layer is of the order $\varepsilon^{1/3}$ and decreases in the space-charge region.

Thus, in the space-charge region the system (2) becomes

$$\left.\begin{aligned} &\varepsilon^{1/3} \frac{dH_e}{d\xi} - \varepsilon^{1/3} H_e \frac{d\varphi^*}{d\xi} = \frac{I_{ec}^*}{\xi^2}, \\ &\varepsilon^{2/3} \Delta\varphi^* = H_e. \end{aligned}\right\} \qquad (4)$$

By introducing the new variable

$$\Phi = \varepsilon^{1/3}\varphi^* = \frac{e\varphi}{T_e}\left(\frac{D}{R_0}\right)^{1/3},$$

the system (4) is changed to

$$\left.\begin{aligned} &\varepsilon^{1/3} \frac{dH_e}{d\xi} - H_e \frac{d\Phi}{d\xi} = \frac{I_{ec}^*}{\xi^2}, \\ &\varepsilon^{1/3} \Delta\Phi = H_e. \end{aligned}\right\} \qquad (4a)$$

In the first equation a small parameter stands in front of a higher derivative. Thus, except for a thin diffusion layer near the body surface, the system (4a) is everywhere equal to

$$\begin{aligned} &-H_e \frac{d\Phi}{d\xi} = \frac{I_{ec}^*}{\xi^2}, \\ &\varepsilon^{1/3} \Delta\Phi = H_e. \end{aligned} \qquad (5)$$

For $\xi = \xi_0$ the field potential on the surface of the body is φ_0, i.e.,

$$\Phi(\xi_0) = \Phi_0 \equiv \frac{e\varphi_0}{T_e}\left(\frac{D}{R_0}\right)^{1/3}. \qquad (6a)$$

On the exterior boundary of the space-charge region at $\xi = 1$, the field potential is of the order T_e/e, so that

$$\Phi|_{\xi \to 1} \to 0. \qquad (6b)$$

Equating the derivatives of the field potential on the exterior boundary of the space-charge region and on the interior boundary of the double layer, we have

$$\frac{d\Phi}{d\xi}(1) = -C. \qquad (6c)$$

The boundary conditions (6a)-(6c) completely describe the solution of the system (5) and the radius of the space-charge region.

The system (5) can be solved as follows. H_e is found from the first equation and substituted into the second. After changing the variables $\xi = 1/\eta$, we have

$$\Phi(\xi) = \left(\frac{2}{3}\frac{I^*_{ee}}{\varepsilon^{1/3}}\right)^{1/3} F_1(\xi),\ F_1(\xi) = \int\limits_{\xi}^{1} \frac{dt}{t^2}\sqrt{1+g-t^3},\ g = \frac{3\varepsilon^{1/3}C^2}{2I^*_{ee}}. \qquad (7)$$

Expression (7) has been derived taking account of the boundary conditions (6b) and (6c). The boundary condition (6a)

$$\Phi(\xi_0) = \Phi_0$$

determines ξ_0, i.e., the radius of the space-charge region:

$$R_c = \frac{R_0}{\xi_0}.$$

The function $F_1(\xi)$ can be expressed in terms of elliptic integrals. However, in calculating the asymptotics for $\xi \ll 1$ or $\xi \to 1$, and in tabulating the function $F_1(\xi)$, it is more convenient to represent the function as an integral (see ref. 7).

If $\xi \ll 1$ we have

$$F_1(\xi) = \frac{1}{\xi}, \quad \Phi(\xi) = \left(\frac{2}{3}\frac{I^*_{ee}}{\varepsilon^{1/3}}\right)^{1/3}\frac{1}{\xi}.$$

Thus, for very large R_c/r ratios, i.e., for very high body potentials when $\varphi_0^{1/2} \gg (T_e/e^{1/2})(R_0/D)^{1/2}$, the space charge near the body does not play a significant role and decreases according to the Coulomb law

$$\varphi = \varphi_0 \frac{R_0}{r}.$$

In this case we have

$$R_c = 1.10 R_0 \left(\frac{\beta}{1+\beta}\right)^{1/2} \left(\frac{e\varphi_0}{T_e}\frac{D}{R_0}\right)^{1/2}. \qquad (8)$$

Thus, for very high body potentials the radius of the space-charge region increases with φ_0 in proportion to $\varphi_0^{1/2}$.

If $\xi \to 1$, we have

$$F_1(\xi) = \sqrt{g}\,(1-\xi), \quad \Phi(\xi) = C(1-\xi).$$

Whence, for relatively low body potentials

$$\varphi_0^* \equiv \frac{e\varphi_0}{T_e}\left(\frac{D}{R_0}\right)^{2/3} \ll 1,$$

the thickness of the space-charge region is small in comparison with the radius of the body. In this case the space-charge region forms a thin charged layer near the surface of the body; this case has been discussed in ref. 2. The dependence of the radius R_c on the body potential φ_0 for $\beta = 1$ and $R_0/D = 100$ is shown in Table 1.

TABLE 1

0.60	1.17	5.0	1.70	25	2.83	100	4.95	900	13.54

Figure 2 shows the variation of the potential in the space-charge region, as given by expressions (7), for $\beta = 1$, $R_0/D = 100$, and for different values of φ_0^*.

Let us substitute expression (7) for the potential $\Phi(\xi)$ into the first equation of the system (5). Thus,

$$H_e(\xi) = \sqrt{\frac{3I^*_{ee}\varepsilon^{1/3}}{2}}\frac{1}{\sqrt{1+g-\xi^3}}.$$

Considering this expression, we have for $r = R_c$

$$\frac{N_e}{N_0} = \frac{1+\beta}{\beta C}\frac{R_0}{R_c}\left(\frac{D}{R_0}\right)^{1/3}.$$

If $\varphi_0^{1/2} \gg (T_e/e)^{1/2}(R_0/D)^{1/2}$, then near the body (at the exterior boundary of the diffusion layer) we obtain

$$\frac{N_e}{N_0} = 1.10\left(\frac{1+\beta}{\beta}\right)^{3/2}\left(\frac{DT_e}{R_0 e\varphi_0}\right)^{1/2}.$$

The variation of electron density in the space-charge region is shown in Fig. 2 for $\beta = 1$, $R_0/D = 100$, and for different values of φ_0^*.

Diffusion layer. In the diffusion layer the electron density is given by the first equation of the system (4a). This equation can be replaced by the approximate expression of ref. 3:

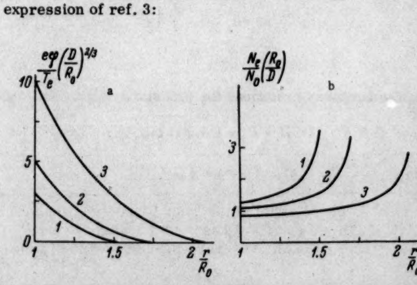

Fig. 2. Variation of the potential (a) and electron (attracted particles) density (b) in the space-charge region for R/D = 100, β = 1, and different φ_0^*: 1) 3; 2) 5; 3) 10.

$$\varepsilon^{1/3}\frac{dH_e}{d\xi}-H_e\frac{d\Phi}{d\xi}(\xi_0)=\frac{\Gamma^*_{ee}}{\xi_0^2}. \tag{9}$$

The corresponding internal variable is $z=(\xi-\xi_0)/\varepsilon^{1/3}$, and Eq. (9) can be reduced to

$$\frac{dH_e}{dz}+H_e\left|\frac{d\Phi}{d\xi}(\xi_0)\right|=\frac{\Gamma^*_{ee}}{\xi_0^2}.$$

The solution of this equation which satisfies the boundary condition $H_e(z=0)=0$ is

$$H_e(z)=\frac{\Gamma^*_{ee}}{\xi_0^2}\left|\frac{d\Phi}{d\xi}(\xi_0)\right|^{-1}\left[1-\exp\left\{-\left|\frac{d\Phi}{d\xi}(\xi_0)\right|z\right\}\right].$$

The uniformly valid ($\xi_0 \le \xi \le 1$) first-order approximation has the form

$$H_e(\xi)=\frac{\Gamma^*_{ee}}{\xi^2}\left|\frac{d\Phi}{d\xi}(\xi)\right|^{-1}-\frac{\Gamma^*_{ee}}{\xi_0^2}\left|\frac{d\Phi}{d\xi}(\xi_0)\right|^{-1}$$
$$\times\exp\left\{-\left|\frac{d\Phi}{d\xi}(\xi_0)\right|\frac{(\xi-\xi_0)}{\varepsilon^{1/3}}\right\}+o(1). \tag{10}$$

From (10) it follows that the diffusion layer thickness l_d is

$$l_d=R_e\varepsilon^{1/3}\left|\frac{d\Phi}{d\xi}(\xi_0)\right|^{-1}.$$

Whence, for $e\varphi_0/T_e \ll (R_0/D)^{2/3}$, we have $l_d \sim R_0^{1/3}D^{2/3}$, as expected. For $(e\varphi_0/T_e)^{1/2} \gg (R_0/D)^{1/2}$, when the field near the body is a Coulomb field, $l_d = R_0(T_e/e\varphi_0)$. In this case the thickness of the diffusion layer is much smaller the Debye radius D.

Particle flux. The total flux of particles to the surface of the body is given by

$$I_e=\Gamma^*_{ee}I_{e0}\frac{1}{\xi_0}=\frac{1+\beta}{\beta}4\pi R_e N_0 D_e. \tag{11}$$

If $\varphi_0^*(D/R_0)^{2/3} \to 0$, the ratio $R_c/R_0 \to 1$, and the flux I_e is equal to $[(1+\beta)/\beta]I_{e0}$, as should be. As is obvious from (8) and (11), at very high body potentials $(e\varphi_0/T_e)^{1/2} \gg (R_0/D)^{1/2}$, we have

$$I_e=1.10I_{e0}\left(\frac{1+\beta}{\beta}\right)^{3/4}\left(\frac{e\varphi_0}{T_e}\frac{D}{R_0}\right)^{1/2}. \tag{12}$$

Thus, when $\varphi_0 \to \infty$, the particle flux increases in proportion to $\varphi_0^{1/2}$.

The variation of the flux I_e/I_{e0} with $\varphi_0^*(D/R_0)^{2/3}$ is shown in Fig. 3 for $\beta = 1$ and $R_0/D = 100$.

Small body ($R_0 \ll D$). For very high body potentials φ_0 the dimensions of the highly perturbed domain (the space-charge region) are much greater than the Debye radius. It can be thus expected that the variation of the field is similar to the case of a large body. The space-charge region (8) is then given by

$$R_c=1.10D\left(\frac{\beta}{1+\beta}\right)^{1/4}\left(\frac{e\varphi_0}{T_e}\frac{R_0}{D}\right)^{1/2}.$$

The condition $R_c \gg D$ is satisfied when

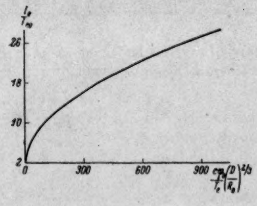

Fig. 3. Total flux of electrons (attracted particles) as a function of body potential φ_0 for $R_0/D = 100$ and $\beta = 1$.

$$\left(\frac{e\varphi_0}{T_e}\right)^{1/2} \gg \left(\frac{D}{R_0}\right)^{1/2}. \tag{13}$$

The electron flux I_e is in this case described by expression (12).

If

$$\frac{e\varphi_0}{T_e} \ll \frac{D}{R_0}, \tag{14}$$

but since as before $e\varphi_0/T_e \gg 1$, the electron flux is[4]

$$\frac{I_e}{I_{e0}}=\frac{e\varphi_0}{T_e}. \tag{15}$$

The dependence of the flux I_e on the potential of a small body is shown in Fig. 4 for $\beta = 1$. Obviously, for very high potentials $e\varphi_0/T_e \sim D/R_0$, only the asymptotic behavior of the function I_e/I_{e0} is known exactly under the conditions (14) and (13). However, the expressions (15) and (12) fit together so that the complete curve can be plotted approximately.

It should be noted in conclusion that throughout this work the mean free paths of the electrons and ions have been assumed to be much smaller than any of the characteristic dimensions of the problem. As the structure of the perturbed domain in the neighborhood of a highly charged body is almost unaffected by the diffusion layer, the above considerations concerning a large body (excepting perhaps the diffusion layer) are valid when the mean free paths of the electrons l_e and ions l_i are much smaller than the thickness of the double layer, the smallest of the remaining dimensions. Thus, as in ref. 2, the analysis has been carried out under the assumption that

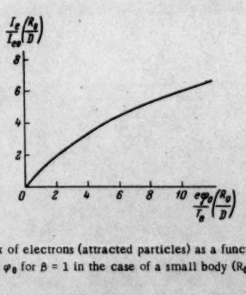

Fig. 4. Total flux of electrons (attracted particles) as a function of body potential φ_0 for $\beta = 1$ in the case of a small body ($R_0 \ll D$).

$$l_e \ll R_0^{1/2} D^{1/2}, \quad l_i \ll R_0^{1/2} D^{1/2}.$$

In the case of a small body, the mean free paths have been assumed negligible in comparison with the dimension of the body.

The authors thank A. V. Gurevich for discussion and I. A. Zhulin for his interest.

The electron energy distribution function in the afterglow is usually assumed to be a Maxwellian. However, one might expect a considerable departure from this distribution for fast electrons. In the present paper we describe a method for the experimental determination of the electron energy distribution and the densities of charged particles and metastable atoms in the afterglow. The results of measurements in helium carried out in a tube 2.7 in diameter at pressures of 1 and 2 torr and currents of 0.45 and 1.8 A are presented. The high-energy part of the distribution function exhibits effects due to metastables.

1. During the last few years a number of papers have reported investigations of the afterglow in the positive column. Investigations of the afterglow yield information on the deionization time, which is of practical importance. In addition, it is possible, under afterglow conditions, to study reactions in which heavy particles (ion and metastable atoms) participate.

The estimate of the decay of electron excitation and ionization in these papers is usually made starting from traditional considerations, using the idea of an electron temperature T_e and a Maxwellian electron energy distribution. However, under afterglow conditions we might expect a considerable departure of the distribution from a Maxwellian for the fast electrons. We consider the processes in a decaying plasma in more detail. For values of the gas pressure p and the tube radius R which are reasonably large ($pR \gg 1$ torr · cm) the plasma deionization process can be divided into two stages. During the first stage there is a rapid cooling of the electrons to a temperature of the order of the temperature of the atoms T_a. The cooling process takes place in a time of the order of $\tau_a \simeq 1/(\delta \nu_a)$, where δ is the fractional energy dissipated in collisions, and ν_a is the electron–atom collision frequency. During the time τ_a the density of the electrons and metastable atoms does not change to any great extent. During the second stage recombination of the charged particles and excitation of the metastable atoms occur. These processes take a much longer time than τ_a. During this stage most of the electrons lie in the energy range from zero to several tens of electron volts. Since electron–electron interactions for electrons with these energies are strong, a Maxwellian distribution is established in this energy range with a certain temperature T_e. The value of T_e may be much greater than T_a, since a number of processes take place in the plasma which lead to the appearance of fast electrons and, as a consequence, to heating of the electron gas. The number of Maxwellian electrons with energies $\varepsilon \gg kT_e$ is very small, so the presence of sources of fast electrons in this energy range can lead to a considerable departure of the distribution function from a Maxwellian; the number of electrons in this range may be much larger than for a Maxwellian distribution characterized by the temperature of the slow electrons T_e.

Processes which give rise to fast electrons include the following.

1. Collisions of the second kind between electrons and metastable atoms.

2. Collisional–radiative recombination.

3. The formation of an atomic ion when two metastable atoms collide.

4. The formation of a molecular ion when two metastable atoms collide.

The role of these processes has been discussed in ref. 1.

The fast electrons which arise in the plasma can dissipate their energy in several ways: a) by interaction with slow plasma electrons; b) by collisions with gas atoms and ions; c) by recombination at the walls of the tube and in the volume. Competition between a, b, and c leads to a situation in which ε_{eff}, the effective energy introduced by the fast electrons into the electron system, is not equal to the initial energy ε; depending on the conditions this quantity can assume any value from zero to the initial energy. The quantity ε_{eff} determines the degree of heating of the slow electrons. To calculate it, it is necessary to know the distribution function of the fast electrons, that is, the distribution function for $\varepsilon \gg kT$. The distribution of the fast electrons is also of independent interest, for example, for estimating the contribution of excitation processes by electron collisions in the afterglow.

A problem similar to that being considered here is considered in ref. 1. However, no measurements were made of the distribution function of the fast electrons, and the theoretical discussion contains errors which make the results obtained in a number of cases not only quantitatively but also qualitatively incorrect. Hence, the problem in this investigation is to measure and calculate the form of the distribution function under afterglow conditions.

2. The measurements are carried out in the afterglow of a periodic discharge in helium at pressures of 1 and 2 torr and currents of 0.45 and 1.8 A. A block diagram of the experimental apparatus is shown in Fig. 1. Voltage pulses with $\tau_1 = 20$ μsec and repetition frequency 2 kHz are applied to the electrodes of the discharge tube. We use a tube 35 cm long with internal diameter of 2.7 cm with cooled electrodes; at the axis, in the central part, there are two cylindrical probes with the following dimensions: length $l_1 = 1.4$; $l_2 = 1.5$ cm, radius $r_1 = 5 \cdot 10^{-3}$, and $r_2 = 3 \cdot 10^{-3}$ cm. The grounded anode of the discharge tube is used as the reference electrode in the probe measurements.

The following afterglow parameters are determined experimentally: the electron energy distribution function, the charged-particle density, and the density of metastable atoms in the 2^3S_1 state. We consider the measurements in detail below.

In our previous paper[2] we have described a pulsed method of measuring the distribution function in a plasma with periodically varying parameters. The measurements in the afterglow use an arrangement based on the switching of the probe current. The basic idea of the method is as follows. An alternating signal of the form

$$\Delta V = A(1 + \cos\omega_1 t)\sin\omega_2 t \tag{1}$$

is introduced into the probe circuit together with a constant bias.

In our investigation $f_1 = \omega_1/2\pi = 400$ Hz, $f_2 = \omega_2/2\pi = 100$ kHz. The probe circuit is opened and closed only during the measurement time. Then, the amplitude of the signal of frequency ω_1, to which the selective circuit is tuned, will contain as the main term a quantity proportional to the second derivative of the probe current with respect to the probe potential at the time t:

$$i_{\omega_1} = \frac{\tau}{T}\left[\frac{A^2}{2}i''(V, t_0) + \frac{7}{64}A^4 i^{\mathrm{IV}}(V, t_0) + \ldots\right]\cos\omega_1 t, \tag{2}$$

where τ is the time at which the switch circuit is closed. The switching frequency of the circuit is $f = 1/T$, where T is the period between discharge current pulses. By varying V for fixed t_0, we can find i″ as a function of V and t_0 for given t_0. By making measurements for different t_0, we obtain i″ (V, t_0) at different afterglow times. The electron energy distribution function is related to i″ (V, t_0) by the well-known Dryuvesteyn relation.[3]

To obtain the absolute values of the distribution function we calibrate the measuring circuit.[4] For the shape of differentiating signal mentioned above the relation between the distribution function and the quantities measured in the experiment is as follows:

$$nf(\varepsilon) = 8.42 \cdot 10^{11}\frac{\sqrt{V}}{A^2 S}\frac{x}{x_k} i_{\omega_1 k}. \tag{3}$$

Here, $nf(\varepsilon)$ is the electron energy distribution function in $\mathrm{eV^{-1}\,cm^{-3}}$, V is the retarding potential of the probe in volts, A is half the peak value of the modulating voltage in volts, S is the area of the probe in $\mathrm{cm^2}$, $i_{\omega 1k}$ is the amplitude of the calibrating current in amperes, x_k is the deflection of the automatic recorder when the calibrating current flows through the probe circuit, and x is the deflection of the recorder in the measurements. The number of particles in the energy range of interest is found by graphical integration of Eq. (3) in the appropriate energy range.

Obtaining the distribution function in the afterglow is known to be a difficult problem. Since the main group of electrons in the decaying plasma has a Maxwellian distribution with mean energy ≈ 0.1 eV, the small oscillations of the space potential (0.1 V) present in our experiments do not enable us to determine the true behavior of the second derivative of the probe current over the range of plasma potentials. Consequently, we cannot measure the space potential from the position of the characteristic points on the curve i″ (V, t_0) or obtain the electron density by integrating the experimental curve of i″ (V, t_0). For this reason we use the following method to determine the charged-particle density. At the afterglow time of interest we find the saturation ion current on an oscilloscope. The temperature of the distribution (in °K) is found from the retarding potentials of the probe, equal to 0.4-0.6 V, from the equation

$$T_e = \frac{11600}{\frac{d\ln i''(V, t_0)}{dV}}. \tag{4}$$

For these electron energies the distribution function is a Maxwellian due to the large part played by Coulomb interactions, while the curve of i″(V) in this region is not distorted by oscillations of the space potential. In the measurement of T_e the value of A is 0.05 V.

From the known temperature T_e and the measured ion saturation current density j, we can find the electron density n from the equation

$$n(T_e + T_a) = 2 \cdot 10^{12}\frac{r}{\lambda_+}\sqrt{MT_a}\, j \ln\frac{l}{r x_0}, \tag{5}$$

where T_a is the temperature of the atoms (in °K), λ_+ is the mean free path of the ions (in cm), M is the atomic weight, j is the ion saturation current density (in mA/cm^2), and l is the probe length.

The quantity $x_0 = (1 + u)(1 + 0.05\,u)$, where

$$u = 2.3\cdot 10^{-2}\left(\frac{V_1^3\lambda_+}{j^2M}\right)^{1/3}\frac{1}{r}.$$

Here, V is the probe potential with respect to the plasma potential. Equation (5) differs from that given in ref. 5 in that the atomic temperature is taken into account on the left side. This is necessary in the afterglow, since the temperatures T_e and T_a are quantities of the same order. The use of probe theory at medium pressures to determine the electron density is due to the fact that the mean free path of the ions for charge exchange is several times smaller than the dimensions of the probe sheath. In calculations using Eqs. (3) and (5) it is necessary to know the space potential V_s. This quantity is found from the potential of a floating probe V_f using the following equation:[4]

$$V_s - V_f = \frac{T_e}{11600}\ln\left(0.7\sqrt{\frac{M}{m}}\,\frac{S}{S_1}\right), \tag{6}$$

where m is the electron mass, M is the mass of the atom, S is the probe area, S_1 is the area on the layer, and T_e is the electron temperature (in °K).

The use of Eq. (6) is justified, since the sheath radius is small at these potentials. Since the mean energy in the afterglow is low, the value of $V_f - V_s$ in helium can be calculated with an accuracy better than 0.2 V from the equation

$$V_f - V_s = 3.5\cdot 10^{-4}T_e. \tag{7}$$

3. To measure the density of metastable atoms in the 2^3S_1 state in the afterglow, we use the radiation absorption method employing two tubes (Fig. 1). Using this method we measure the intensity of the radiation from tube 1 which passes through the absorbing tube 2. This quantity, however, may be considerably smaller than the intensity of the radiation of tube 2. Hence, in measurements of this type it is important for the recording system to record only the signal from tube 1. To solve this problem we use an alternating-current recording circuit employing synchronous detection. A characteristic of this circuit is the fact that it enables measurements to be made at any instant of time of interest under periodically recurrent discharge conditions. The principle of operation of the circuit is illustrated in Figs. 1 and 2.

In tube 1, of radius 1 cm and containing helium at a pressure of 1 torr, a dc discharge is ignited (i = 150 mA). The radiation from this tube passes successively through the modulator 3 and the tube 2, and together with the natural radiation of tube 2 is incident on the entrance slit of the monochromator 4. The time behavior of this flux is shown in Fig. 2c. The signal from the output of the photomultiplier 5 is fed to an emitter follower 6, and then to an electronic switch 7. The electronic switch is opened at a frequency equal to the frequency at which the tube 2 strikes. The length of the opening pulse τ_3 and its delay τ_2 with respect to the discharge pulse are controlled. The value of the delay is determined by the phase of the afterglow in which the measurements are made. The form of the signal at the output of the electronic switch is shown in Fig. 2d. This signal is applied to a narrow-band amplifier 8 and then to the synchronous detector 9. The narrow-band amplifier is tuned to the modulation frequency of the light flux of tube 1, and is equal to 600 Hz. The reference voltage of the synchronous detector of the same frequency operates the unit 11, consisting of a photodiode and an amplifier. In the signal applied to the input of the narrow-band amplifier the amplitude of the harmonic at the modulation frequency is proportional to the light flux of tube 1 only. Consequently, the measuring voltmeter 10 records the light flux from tube 1 at the chosen instant of afterglow.

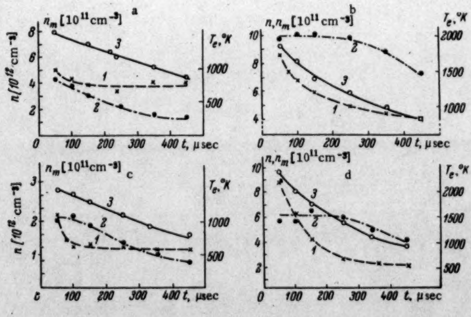

Fig. 3. Variation of electron temperature (1), electron density (2), and density of metastable atoms in the 2^3S_1 state (3) in the afterglow. a) Pulse current 1.8 A, pressure torr; b) current pulse 0.45 A, pressure 2 torr; c) pulse current 1.8 A, pressure 1 torr; d) pulse current 0.45 A, pressure 1 torr.

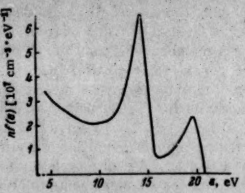

Fig. 4. Typical form of the electron energy distribution function in the afterglow. Helium pressure 1.5 torr, pulse current 0.45 A. The measurement is made 50 μsec after the discharge pulse ceases.

We measure the relative absorption of the 3889 Å triplet line of helium. At the pressures and currents which we use the radiation and absorption profiles of each of the triplet lines can be assumed to be of Doppler form,[6] and the absorption in tube 1 is not taken into account. The temperature of the atoms of the radiating and absorbing tube is taken to be 400°K. It can be shown that a change in the atom temperature of 100°K leads to an error in determining the density of the metastable atoms of less than 10%.

The results obtained for the electron temperature, the charged-particle density, and the density of the metastable atoms are shown in Fig. 3. A typical experimental distribution function in the afterglow is shown in Fig. 4. Note the maxima in the region of 15 and 20 eV. These characteristics are due, respectively, to reactions in which two metastable atoms participate, and collisions of the second kind between electrons and metastable atoms.

The results of systematic measurements of the distribution function, a discussion of the experimental material, and theoretical calculations of the distribution function are given in the second part of this paper.

Electron energy distribution in the afterglow. II

A. B. Blagoev, Yu. M. Kagan, N. B. Kolokolov and R. I. Lyagushchenko

A. A. Zhdanov Leningrad State University

(Submitted July 2, 1973)
Zh. Tekh. Fiz., 44, 339-347 (February 1974)

The results of probe measurements on the distribution function in the afterglow of a helium plasma at pressures of 1 and 2 torr and currents of 0.45 and 1.8 A are presented. The distribution function in the energy range 4-20 eV has a complex nonmonotonic form. The number of electrons in this energy range is many orders of magnitude greater than in a Maxwellian distribution with the temperature of the slow electrons T_e. These characteristics are due to the production of fast electrons in reactions in which metastable atoms participate. The results of the experiment are compared with theoretical calculations of the distribution function in the afterglow. The agreement is satisfactory. Absolute measurements of the distribution function of the fast electrons and a comparison with theoretical calculation enable us to determine the constants and cross sections of the elementary processes. The following values are obtained: the cross section $\sigma_1 \approx 0.6 \cdot 10^{-16}$ cm^2 for collisions of the second kind $He(2^3S_1) + e \rightarrow He(1^1S_0) + e$, the constant $\beta_2 \approx 10^{-9}$ cm$^3 \cdot$ sec^{-1} for the reaction $He(2^3S_1) + He(2^3S_1) \rightarrow He_2^+ + e$, and the constant $\beta_3 \approx 2 \cdot 10^{-9}$ cm$^3 \cdot$ sec^{-1} for the reaction $He(2^3S_1) + He(2^3S_1) \rightarrow He^+ + He + e$.

1. In the preceding paper[1] we describe a method of investigating the electron energy distribution in the afterglow of the positive column and give results of measurements in a helium plasma at pressures of 1 and 2 torr and currents of 0.45 and 1.8 A.

Systematic measurements of the distribution function in absolute units for different stages of the afterglow are shown in Figs. 1 and 2. Figure 3 shows the change in the number of electrons with time for different energy ranges. It can be seen from Fig. 1 that the distribution function in the energy range 4-20 eV has a complex nonmonotonic form. The number of electrons in this energy range is many orders of magnitude greater than in a Maxwellian distribution at the temperature of the slow electrons T_e, and the decrease with time of the number of fast electrons is comparatively slow. These characteristics can be explained by assuming that fast electrons are produced as a result of a number of reactions in which metastable atoms participate. Thus, the presence of a maximum in the energy range around 20 eV can be due to the reaction

$$He(2^3S_1) + e \rightarrow He(1^1S_0) + e. \qquad (1)$$

In this reaction electrons are created in an energy range of the order of several kT_e in the region of 19.8 eV. The maximum in the energy range around 15 eV can be due to the reaction

$$He(2^3S_1) + He(2^3S_1) \rightarrow He_2^+ + e. \qquad (2)$$

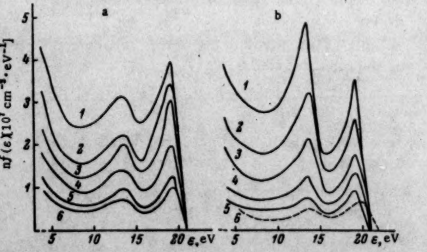

Fig. 1. Form of the distribution function in the afterglow. t, μsec: 1) 50; 2) 100; 3) 150; 4) 250; 5) 350; 6) 450; p = 2 torr, i, A: a) 1.8; b) 0.45.

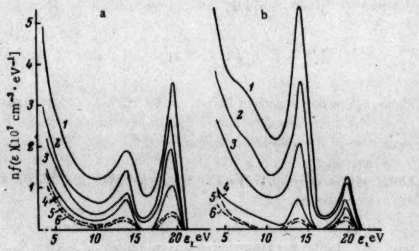

Fig. 2. Form of the distribution function in the afterglow. The notation is the same as in Fig. 1; p = 1 torr.

In this reaction electrons are produced[2] with energies of about 15 eV. The continuous energy spectrum in the range 4-12 eV occurs as a result of the reaction

$$He(2^3S_1) + He(2^3S_1) \rightarrow He^+ + He + e. \qquad (3)$$

From the data in ref. 2, in this reaction electrons may be produced over a wide energy range from zero to 14.5 eV.

In collisional–radiative recombination the mean increment in energy of the electron is about 0.35 eV, so the effect of recombination on the shape of the distribution in the energy range 4-20 eV should not be very great. However, this process can lead to heating of the slow electrons.

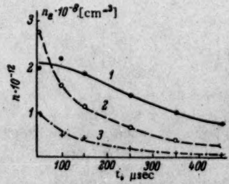

Fig. 3. The variation of the number of electrons with time for different energy ranges. 1) Total number of electrons n; 2) number of electrons n_ε with energies ε = 16 eV, i = 1.8 A, p = 1 torr.

All these reactions also occur in a steady discharge, but their effect is masked by the high electron flux in the high energy range of velocity space due to heating of the electrons in the electric field. These reactions can play a role in the region outside the steady discharge where there is no electric field. Such conditions obtain in the experiment described in ref. 3.

2. We now give a theoretical analysis of the electron energy distribution in the afterglow. The distribution function of the fast electrons $f_0(\varepsilon)$ can be obtained from the following considerations. If the characteristic times of variation of electron and metastable atom densities is much greater than the relaxation time of the electron energy, the problem can be regarded as quasistationary, and we can omit the derivative with respect to time in the kinetic equation. Then, if fast-electron sources are present, the kinetic equation for the distribution function $f_0(\varepsilon)$ in the energy range $\varepsilon \gg kT_e$ can be written in the form

$$\sqrt{\frac{2m}{\varepsilon}}\frac{d}{d\varepsilon}\varepsilon j_\varepsilon+\left(\frac{1}{\tau}+\nu^*\right)f_0-R(\varepsilon)=0. \qquad (4)$$

Here, j_ε is the electron flux density through the surface of energy ε in velocity space due to elastic collisions with atoms and interelectron interaction, τ is the lifetime of the electrons with ε, ν^* is the frequency of inelastic collisions with atoms, and $R(\varepsilon)$ is the density of the sources of fast electrons.

Using the usual expressions for the electron–electron and electron–atom collision operators,[4] we obtain the following expression for j_ε:

$$j_\varepsilon=-\sqrt{\frac{\varepsilon}{2m}}\left[\nu_e(\varepsilon)\left(kT_e\frac{df_0}{d\varepsilon}+f_0\right)\delta\nu_a(\varepsilon)\left(kT_a\frac{df_0}{d\varepsilon}+f_0\right)\right]. \qquad (5)$$

Here, $\nu_e(\varepsilon) = 2\sqrt{2}\pi e^4 Ln/\sqrt{m}\varepsilon^{3/2}$ is the electron–electron collision frequency, L is the Coulomb logarithm, $\nu_a(\varepsilon)$ is the frequency of elastic collision with atoms, and $\delta = 2m/M$ is the fractional energy dissipated per collision.

In problems of the relaxation of fast electrons with $\varepsilon \gg kT_e$, kT_a, terms with $(df_0)/(d\varepsilon)$ in Eq. (5) can be neglected.[5] The physical meaning of this approximation is that the fast electrons which arise due to the action of sources are mainly slowed down by collisions with slow electrons and atoms.

Using Eq. (5) we write Eq. (4) in the form

$$\frac{1}{\sqrt{\varepsilon}}\frac{d}{d\varepsilon}\left[\varepsilon^{\frac{3}{2}}(\nu_e+\delta\nu_a)f_0\right]-\left(\frac{1}{\tau}+\nu^*\right)f_0+R=0. \qquad (6)$$

The solution of Eq. (6) is the function

$$f_0=\frac{1}{\varepsilon^{3/2}(\nu_e+\delta\nu_a)}\int_\varepsilon^\infty R(\varepsilon')\exp\left[-\int_\varepsilon^{\varepsilon'}\frac{(1+\nu^*\tau)\,d\varepsilon}{\varepsilon\tau(\nu_e+\delta\nu_a)}\right]\sqrt{\varepsilon'}\,d\varepsilon'. \qquad (7)$$

The form of function (7) depends on the value of the parameter $(1 + \nu^*\tau)/[(\nu_e + \delta\nu_a)\tau]$ for a given value of the energy ε. When this parameter is much smaller than unity, i.e., the "absorption" time of a fast electron $\tau/(1 + \nu^*\tau)$ is much greater than the "retardation" time $1/(\nu_e + \delta\nu_a)$,

$$f_0\simeq\frac{1}{\varepsilon^{3/2}(\nu_e+\delta\nu_a)}\int_\varepsilon^\infty R(\varepsilon')\sqrt{\varepsilon'}\,d\varepsilon'. \qquad (8)$$

For a single-energy source $R = I\delta(\varepsilon - \varepsilon_0)$ in this case we obtain a step distribution

$$f_0=\begin{cases}\dfrac{I}{\varepsilon^{3/2}(\nu_e+\delta\nu_a)} & \text{for } \varepsilon<\varepsilon_0,\\ 0 & \text{for } \varepsilon>\varepsilon_0.\end{cases} \qquad (9)$$

In the opposite limiting case $(1 + \nu^*\tau)/[(\nu_e + \delta\nu_a)\tau] \gg 1$ the exponent in Eq. (7) has a sharp maximum when $\varepsilon' = \varepsilon$, so that $R(\varepsilon')\sqrt{\varepsilon'}$ can be removed from under the integral when $\varepsilon' = \varepsilon$ and

$$\int_\varepsilon^{\varepsilon'}\frac{(1+\nu^*\tau)}{\varepsilon\tau(\nu_e+\delta\nu_a)}\frac{d\varepsilon}{\varepsilon}\simeq\frac{1+\nu^*\tau}{\varepsilon\tau(\nu_e+\delta\nu_a)}(\varepsilon'-\varepsilon),$$

when

$$f_0\simeq\frac{R(\varepsilon)\tau(\varepsilon)}{1+\nu^*\tau}. \qquad (10)$$

The form of the distribution in this case is determined to a large extent by the form of the source. For a single-energy source a single-energy distribution is obtained.

It follows from the results obtained in ref. 2 that the distribution has a form similar to (10) for any value of the parameter $(1+\nu^*\tau)/[(\nu_e+\delta\nu_a)\tau \gg 1$. This is due to the fact that the differential operators of electron–electron collisions and of elastic collisions of electrons with atoms are written in the relaxation time approximation, which is inadmissible.

The electron lifetime τ is determined by recombinations in the volume, and diffusion to the walls of the tube. The potential difference between the walls and the center of the tube, which arises when there is ambipolar diffusion of the slow electron, has a value of the order of several $(kT_e)/e$. For this reason we assume that the electrons with energies $\varepsilon \gg kT$ drift to the walls under free diffusion conditions. If we assume that the reflection coefficient of the fast electrons at the walls is zero, the diffusion time $\tau_D = r^2/[5.8D(\varepsilon)]$, where r is the radius of the tube, and $D(\varepsilon) = 2\varepsilon/(3m\nu_a)$ is the free diffusion coefficient. For the inert gases the value of τ_D for $pr \leqslant 10$ torr · cm turns out to be very much smaller than the volume recombination time, so that we assume below that $\tau = \tau_D$.

In the case of helium the source density can be represented in the form

$$R(\varepsilon)=R_1(\varepsilon)+R_2(\varepsilon)+R_3(\varepsilon),$$

where R_1, R_2, and R_3 are the source densities due to processes (1), (2), and (3). For process (1) we have

$$R_1(\varepsilon)=\frac{g_a}{g_m}\frac{nn_m}{n_a}\nu^*(\varepsilon)\left(\frac{m}{2\pi kT_e}\right)^{3/2}\exp\left(-\frac{\varepsilon-\varepsilon_1}{kT_e}\right), \qquad (11)$$

where n_m and n_a are the densities of metastable and normal atoms, ε_1 is the excitation energy of the metastable atoms, and g_a and g_m are statistical weights. In writing Eq. (11) we assume that the slow electrons have a Maxwellian distribution, and we use the relation between the cross sections of collisions of the first and second kinds. For R_2 and R_3 we use the expression given in ref. 2,

$$R_2 = \frac{\beta_2 n_m^2}{g(\varepsilon_2)} \delta(\varepsilon - \varepsilon_2), \qquad (12)$$

$$R_3 = \frac{(2m)^{3/2} \beta_3 n_m^2}{\pi^2 \varepsilon_3^3} (\varepsilon_3 - \varepsilon)^{3/2} \Theta(\varepsilon_3 - \varepsilon), \qquad (13)$$

where $\varepsilon_2 = 15$ eV, $\varepsilon_3 = 14.5$ eV, β_2 and β_3 are the rate constants of the reactions (2) and (3), $\Theta(x) = 1$ (for $x \geq 0$) and 0 (for $x < 0$), and $g(\varepsilon) = 4\pi\sqrt{2\varepsilon}/m^{3/2}$ is the density of states of an electron with energy ε.

The collision frequency ν_a in the energy region $\varepsilon \geq 4$ eV for helium can be assumed constant, and is given by[6]

$$\nu_a = 2.3 \cdot 10^9 p. \qquad (14)$$

Substituting Eqs. (11), (12), (13), and (14) in Eq. (7) we can obtain the final form of the distribution for helium. Expression (11) for $\varepsilon - \varepsilon_1 \gg kT_e$ is exponentially small, so that the distribution function turns out to be practically zero everywhere for $\varepsilon > \varepsilon_1$, with the exception of a small region of the order of kT_e. Since $\nu^*(\varepsilon) = 0$ for $\varepsilon \leq \varepsilon_1$, the quantity $R_1(\varepsilon)$ has a sharp maximum in the region $\varepsilon - \varepsilon_1 \approx kT_e$. Hence, the contribution of inelastic collisions to the exponent can be estimated by means of the parameter

$$a^2 = \frac{\nu^*(\varepsilon_1 + kT_e)}{\nu_e(\varepsilon_1) + \delta\nu_a(\varepsilon_1)} \frac{kT_e}{\varepsilon_1}.$$

The factor $(kT_e)/\varepsilon_1$ has the physical meaning of the fractional energy an electron of energy $\varepsilon \simeq \varepsilon_1 + kT_e$ must lose to leave the inelastic collision region. For helium with $kT_e \lessdot 0.2$ eV, $a^2 \leq 10^{-2}$, so that in all the subsequent equations we assume $\nu^* = 0$.

Taking these factors into account, we can write the following expression for the electron energy distribution in the helium plasma:

$$\begin{aligned} nf(\varepsilon) = g(\varepsilon) f_0 = {} & \frac{16}{\pi} \left(\frac{\varepsilon_1}{\varepsilon_3}\right)^3 \frac{\beta_3 n_m^2}{\varepsilon_3 \nu_e(\varepsilon_1)} \frac{\sqrt{x}}{1 + \gamma x^{3/2}} \\ & \times \int_x^{x_3} (x_3 - x')^{3/2} \exp\left(-k^2 \int_x^{x'} \frac{x^{3/2} dx}{1 + \gamma x^{3/2}}\right) \sqrt{x'} dx' \\ & + \frac{\beta_2 n_m^2 \Theta(x_2 - x)}{\nu_e(\varepsilon_1) \varepsilon_1} \frac{\sqrt{x}}{1 + \gamma x^{3/2}} \exp\left(-k^2 \int_x^{x_2} \frac{x^{3/2} dx}{1 + \gamma x^{3/2}}\right) \\ & + \frac{\beta_1 n n_m}{\nu_e(\varepsilon_1) \varepsilon_1} \frac{\Theta(1 - x) \cdot \sqrt{x}}{1 + \gamma x^{3/2}} \exp\left(-k^2 \int_x^1 \frac{x^{3/2} dx}{1 + \gamma x^{3/2}}\right). \end{aligned} \qquad (15)$$

Here,

$$x = \frac{\varepsilon}{\varepsilon_1}, \; x_2 = \frac{\varepsilon_2}{\varepsilon_1}, \; x_3 = \frac{\varepsilon_3}{\varepsilon_1}, \; k^2 = \frac{5.8 \cdot D(\varepsilon_1)}{r^2 \cdot \nu_e(\varepsilon_1)}, \; \gamma = \frac{\delta\nu_a}{\nu_e(\varepsilon_1)},$$

and β_1, β_2, β_3 are the rate constants of the processes (1), (2), and (3).

All of the above considerations pertain to electrons with $\varepsilon \gg kT_e$. The electron distribution function ($\varepsilon \lessdot kT$) will be a Maxwellian with temperature T_e, which in general will not be equal to the temperature of the atoms T_a. The Maxwell distribution for slow electrons will be established due to interelectron interaction, which is very strong for energies $\varepsilon \simeq 0.01$-0.1 eV.

The temperature of the slow electrons T_e is determined by the following energy balance equations:

$$euEn + E_{\mathrm{eff}} - H = 0. \qquad (16)$$

Here, H is the reduction in the energy of the electron gas in unit volume and in unit time due to collisions between slow electrons and atoms, and E_{eff} is the similar increment in energy due to the production of fast electrons; the term euEn takes account of the possible heating of the electrons by the residual electric field. The quantity H is given by the usual expression

$$H = \delta\nu_{\mathrm{eff}}(T_e) \frac{3}{2} k (T_e - T_a) n. \qquad (17)$$

For helium, the transport cross section is independent of the energy in the low-energy range. In this case we have

$$\nu_{\mathrm{eff}}(T_e) = \frac{4}{3} \sqrt{\frac{8kT_e}{\pi m}} \frac{1}{\lambda}, \quad u = \frac{8eE\lambda}{3\pi m} \left(\frac{8kT_e}{\pi m}\right)^{-1/2},$$

and $\lambda = 1/17p$ is the mean free path of an electron.[7]

The quantity E_{eff} is equal to the energy transferred by the fast electrons to the slow electrons. The value of E_{eff}, due to processes (1), (2), and (3), is

$$E_{\mathrm{eff}} = \int_0^\infty \varepsilon S_e(f_0) g(\varepsilon) d\varepsilon. \qquad (18)$$

Here,

$$S_e(f_0) = -\sqrt{\frac{2m}{\varepsilon}} \frac{d}{d\varepsilon} \left(\nu_e \sqrt{\frac{\varepsilon^3}{2m}} f_0\right) \qquad (19)$$

is the interelectron collision operator for $\varepsilon \gg kT_e$, and f_0 is the distribution function of the fast electrons given by Eq. (7). Since $kT_e \ll \varepsilon_1, \varepsilon_2, \varepsilon_3$, the lower limit of integration in Eq. (18) is zero. Substituting Eqs. (7) and (19) in Eq. (18), integrating by parts, and changing the order of integration, we obtain the following general expression for E_{eff}:

$$E_{\mathrm{eff}} = \int_0^\infty d\varepsilon' R(\varepsilon') g(\varepsilon') \int_0^{\varepsilon'} \frac{\nu_e}{\nu_e + \delta\nu_a} \exp\left[-\int_\varepsilon^{\varepsilon'} \frac{d\varepsilon}{\varepsilon(\nu_e + \delta\nu_a)\tau}\right]. \qquad (20)$$

It is easy to understand the physical meaning of Eq. (20) by noting that the quantity

$$\varepsilon_{\mathrm{eff}}(\varepsilon') = \int_0^{\varepsilon'} \frac{\nu_e}{\nu_e + \delta\nu_a} \exp\left[-\int_\varepsilon^{\varepsilon'} \frac{d\varepsilon}{\varepsilon(\nu_e + \delta\nu_a)\tau}\right] d\varepsilon \qquad (21)$$

can be interpreted as an effective energy introduced by the fast electrons with initial energies ε' into the system of slow electrons. For $(\nu_e + \delta\nu_a)\tau \gg 1$, we have

$$\varepsilon_{\text{eff}} = \int_0^{\varepsilon'} \frac{\nu_e}{\nu_e + \delta\nu_a}\, d\varepsilon. \qquad (22)$$

If $\nu_e\tau \gg 1$, $\nu_e \gg \delta\nu_a$ we have

$$\varepsilon_{\text{eff}} \simeq \varepsilon'. \qquad (23)$$

For $(\nu_e + \delta\nu_a)\tau \ll 1$ the exponential in Eq. (21) has a sharp peak for $\varepsilon = \varepsilon'$, which enabled us to carry out the integration in general form. In this case we obtain

$$\varepsilon_{\text{eff}} \simeq \nu_e\tau\varepsilon'. \qquad (24)$$

The physical meaning of Eqs. (22)-(24) is obvious.

If we substitute in Eq. (20) the expression for $R(\varepsilon)$ in the form of the sum $R = R_1 + R_2 + R_3$, where R_1, R_2, and R_3 are defined by Eqs. (11), (12) and (13), then E_{eff} splits into three terms $E_{\text{eff}}(1)$, $E_{\text{eff}}(2)$, and $E_{\text{eff}}(3)$. We will confine ourselves to writing expressions for these quantities for the case in which

$$\frac{k^2}{1+\gamma} = \frac{1}{(\nu_e + \delta\nu_a)\tau}\bigg|_{\varepsilon=\varepsilon_1} \gg 1,$$

since it is this situation which occurs under the experimental conditions. Taking Eqs. (24), (11), and (12) into account we obtain

$$E_{\text{eff}}(1) = \frac{\varepsilon_1\beta_1 n n_m}{k^2}, \qquad (25)$$

$$E_{\text{eff}}(2) = \frac{\varepsilon_2\beta_2 n_m^2}{k^2 x_2^{5/4}}. \qquad (26)$$

In the expression

$$E_{\text{eff}}(3) = \int_0^{\varepsilon_3} R_3(\varepsilon')\, g(\varepsilon')\, \varepsilon_{\text{eff}}(\varepsilon')\, d\varepsilon' \qquad (27)$$

one must not substitute ε_{eff} from Eq. (24) since the conditions under which Eq. (24) can be used may not apply when ε' is only several times less than ε_3, because $\nu_e\tau \sim 1/\varepsilon'^{5/2}$. For an approximate estimate of $E_{\text{eff}}(3)$ we divide the region of integration into two regions $0 < \varepsilon' \le \varepsilon_0$ and $\varepsilon_0 < \varepsilon' < \varepsilon_3$, where ε_0 is defined by the condition $\nu_e(\varepsilon_0)\tau(\varepsilon_0) = 1$. When $\varepsilon' < \varepsilon_0$ we put $\varepsilon_{\text{eff}} \simeq \varepsilon'$, and the contribution to the integral from the region $\varepsilon' > \varepsilon_0$, where ε_{eff} falls sharply, can be neglected. We then obtain from Eq. (27)

$$E_{\text{eff}}(3) = \beta_3 n_m^2 \frac{32}{\pi}\varepsilon_3 \int_0^{\sqrt{\frac{\varepsilon_0}{\varepsilon_3}}} t^4(1-t^2)^{3/2}\, dt \equiv \beta_3 n_m^2 \Delta\varepsilon_3. \qquad (28)$$

An expression for the integral in Eq. (28) is derived, for example, in ref. 8. The quantity $\Delta\varepsilon_3$ has the meaning of the mean energy introduced by an electron produced by process (3) into the system of slow electrons.

In expression (16) it is also necessary to take account of the contribution of the collisional–radiative recombination process. The fast electron produced in the collisional–radiative recombination process[9] has a mean energy $\varepsilon = 0.35$ eV. For these energies $\nu_e \gg \delta\nu_a$, $\nu_e\tau \gg 1$, and, consequently, we can assume that the energy ε_4 is completely transferred to the slow electrons. Then we have

$$E_{\text{eff}}(4) = \varepsilon_4\beta_4(n)\, n^2, \qquad (29)$$

where $\beta_4(n)$ is the recombination rate constant. Substituting Eqs. (17), (25), (26), (28), and (29) in Eq. (16) we obtain an expression which gives the value of the electron temperature:

$$\delta\nu_{\text{eff}}(T_e)\frac{3}{2}k(T_e - T_a) = \frac{\Delta\varepsilon_3\beta_3 n_m^2}{n} + \frac{\varepsilon_2\beta_2 n_m^2}{k^2 x_2^{5/4} n} + \frac{\varepsilon_1\beta_1 n_m}{k^2} + \varepsilon_4\beta_4 n. \qquad (30)$$

Heating of the slow electrons in the afterglow has been discussed previously.[2,10,11] Expression (13) differs from the corresponding expressions in refs. 10 and 11 in that it takes account of the fact that not all the energy of the fast electrons which originate in the plasma is transferred to the slow electrons. For example, for processes (1) and (2) the fraction of the energy transferred to the slow electrons under our experimental conditions is small. As regards ref. 2, our expression (13) for $E_{\text{eff}}(2)$ is close to the expression obtained in ref. 2, but the expressions for $E_{\text{eff}}(1)$ and $E_{\text{eff}}(3)$ differ considerably. It should be noted that process (3) makes a considerable contribution to the heating.

3. We now discuss the results. As can be seen from Eq. (15), the nature of the distribution function in the region of fast electrons depends on the rate constants β_1, β_2, β_3 of the reactions (1), (2), and (3). The values of these constants cannot be regarded as well established. For example, for the constant β_1 the data given in the literature differ by an order of magnitude.[12-14] There is as yet no single opinion as regards which of the reactions in which two metastable atoms participate – (2) or (3) – takes preference in the plasma of the afterglow, and in the experiments which we made we measured the overall coefficient $\beta_2 + \beta_3$ of these reactions.

It is possible, by comparing results of the calculations of the distribution function with the experimental curves, to obtain values of these constants. Thus, the number of electrons in the energy range 16-20 eV is determined by reaction (1). Substituting in expression (15) the experimentally obtained values of the overall electron density and the density of the metastable atoms, and integrating it over this energy range, we obtain a quantity which depends only on the coefficient β_1. Comparing this number of fast electrons with the experimental value, we find the value of β_1. The value of β_1 found in this way varies from $1.9 \cdot 10^{-9}$ to $0.6 \cdot 10^{-9}$ cm$^3 \cdot$ sec^{-1}, depending on the conditions.

Taking into account the change in electron temperature we obtain a value $\sigma_1 = 0.6 \cdot 10^{-16}$ cm^2 for the cross section for collisions of the second kind, which is constant to within 20%. This result is in good agreement with the results obtained in ref. 13.

To determine the constant β_2 we can use the following considerations. As can be seen from Eq. (10) for small values of the parameter $(\nu_e + \delta\nu_a)\tau$ the distribution func-

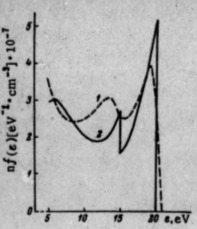

Fig. 4. Comparison between the experimental distribution function (1) and the theoretical distribution function (2). i = 1.8 A, p = 2 torr, t = 50 μsec.

tion is proportional to the source density R(ε). Hence, when the parameter $(\nu_e + \delta\nu_a)\tau/_{\varepsilon=\varepsilon_2} \simeq 0.01$, we can assume that the number of electrons in the energy range 10–16 eV is due to the process (2), since the source density of the process (3) is small for these energies. By choosing the appropriate experimental conditions we find $\beta_2 \simeq 10^{-9}\ \mathrm{cm}^3 \cdot \mathrm{sec}^{-1}$.

By proceeding in the same way we can find the value of the constant β_3. Its value is found to be $2 \cdot 10^{-9}\ \mathrm{cm}^3 \cdot \mathrm{sec}^{-1}$. The overall value $\beta_2 + \beta_3 \simeq 3 \cdot 10^{-9}\ \mathrm{cm}^3 \cdot \mathrm{sec}^{-1}$ is in fairly good agreement with the value of $2 \cdot 10^{-9}\ \mathrm{cm}^3 \cdot \mathrm{sec}^{-1}$ given in the literature.[15]

Figure 4 shows the distribution functions calculated theoretically and measured experimentally. In the calculations we use values of the electron density and the density of metastable atoms used in the first part of this paper,[1] and also the values of the rate constants of reactions (1), (2), and (3) which we obtain. As can be seen, the theoretical and experimental curves agree satisfactorily. The slight differences may be due to the comparatively large amplitude of the differentiating signal when measuring the distribution function. The part played by this effect in distorting the shape of the experimental curve can be seen from Fig. 2. Curves 1–4 are obtained with an amplitude of the differentiating signal A = 0.7 V, while curves 5–6 are obtained with an amplitude A = 1 V. The broadening of the curves as A is increased is very noticeable. In Fig. 1 all the curves are obtained with A = 0.7 V. An exception is curve 6 of Fig. 1b, for which A = 1 V. We carry out control measurements with different amplitudes of differentiating signals A = 0.5–1.1 V. As the amplitude is increased the shape of the curve changes somewhat, but the electron density determined in the energy range 5 eV from the different curves differs by no more than 10%. Hence, to obtain β_1, β_2, β_3 we use integration of the distribution function in this energy range.

TABLE 1. Comparison of the Values of the Electron Temperature (°K) Calculated from Eq. (30), with the Measured Values

p, torr	i = 1.8 A				i = 0.46 A			
	t = 50 μsec		t = 450 μsec		t = 50 μsec		t = 450 μsec	
	theory	experiment	theory	experiment	theory	experiment	theory	experiment
1	900	1100	740	570	1810	2150	530	530
2	880	1000	770	750	1750	1750	740	850

We now analyze the results obtained from the measurements of electron temperature. Table 1 compares values of T_e, °K, calculated from Eq. (30), with the measured values. Taking into account the possible experimental error, which is about 15%, and the approximate nature of the calculations, the agreement is quite satisfactory. The calculation shows that for large values of the parameter k^2 it is process (3) of processes (1)–(4) which makes the main contribution to the heating of the electrons. The comparatively high values of the electron temperature in the initial stages of the afterglow for i = 0.45 A is due to the presence of a residual electric field $E/p \simeq 0.07\ \mathrm{V/cm \cdot torr}$.

The following main conclusions can be drawn.

1. The number of fast electrons in the afterglow is relatively large (about 10^8–$10^9\ \mathrm{cm}^{-3}$), and many orders of magnitude greater than for a Maxwell distribution with temperature $T_e \simeq 300$–2000°K. It is necessary to bear this fact in mind when estimating the excitation processes in the afterglow.

2. Absolute measurements of the distribution function of the fast electrons are a convenient method of determining the constants of elementary processes. In particular, this method enables the constants of processes (2) and (3) to be found separately.

It should be emphasized that when determining the constants β_2 and β_3 separately, we used the data from ref. 2 on the spectrum of electrons formed in these reactions. The form of this spectrum has not yet been finally established. If it changes, the values of the constants β_2 and β_3 may also change. On the other hand, the value of $\beta_2 + \beta_3$ which we have found depends only slightly on the shape of this spectrum.

Radiation energy of a magnetoplasma compressor

V. I. Berkov and A. I. Morozov

(Submitted April 17, 1973)
Zh. Tekh. Fiz., 44, 348-353 (February 1974)

The spectral and spatial energy densities of a magnetoplasma compressor are studied. Most of the radiated energy is in the vacuum-UV region. The radiation energy is a strong function of the voltage to which the bank is charged and the gas pressure.

One of the most important considerations in plasma experiments is the energy balance. The energy balance established for an actual system can be used to evaluate the operating efficiency of the system and to monitor the accuracy of measurements. In a magnetoplasma compressor,[1-3] the energy stored in the capacitor bank is converted into the kinetic energy of the particles, radiated energy, energy evolved at the electrodes, and energy liberated as a result of Joule heating in the supply cables.

We report here on a bolometer study of the radiated energy in the discharge volume of a magnetoplasma compressor.

THE MK-10 MAGNETOPLASMA COMPRESSOR

The experiments are carried out on the apparatus whose electrode unit is shown in Fig. 1. This unit consists of a conical cathode, 12 anode rods, an insulator, and eight thermal valves. The electrodes are made of copper, and the insulator is alundum. Gas is injected from the eight thermal valves for 250 μsec. The anode rods are arranged in a circle 220 mm in diameter. The cathode is 120 mm in diameter. The schematic circuit of the compressor consists of the capacitor bank for the discharge, the valve bank, the dc power supplies which charge the band, the system which produces the ignition pulse, and the blocking system. The apparatus is fed from a capacitor bank with C = 2400 μF and U = 5 kV. The discharge current and voltage are functions of the pressure and nature of the working gas (hydrogen or air). At low pressures (P ≤ 0.3 torr) the discharge is aperiodic. For hydrogen the current is aperiodic even at moderate pressures (P ~ 1 torr). The maximum discharge current for operation in air is 350 kA, and that in hydrogen is 250 kA. The half-period of the discharge is 65 μsec. The total circuit inductance is 200 cm. The experiments are carried our under various operating conditions of the MK-10 (during injection of the working gas from the valves and with a preliminary filling of the vacuum chamber, and at various bank voltages). Various filters (gaseous, quartz, and glass) are used to study the spectral distribution of the energy.

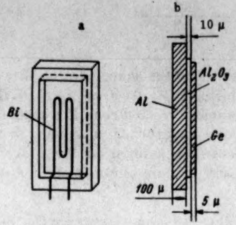

Fig. 2. The bolometer detectors.

BOLOMETER DESIGN AND MEASUREMENT CIRCUIT

The bismuth bolometer is made of aluminum foil d = 35 μ thick with an oxide layer d_2 = 5 μ thick. The thermistor on the surface of the oxide film of the bismuth bolometer consists of an alloy of 99.4% Bi and 0.6% Pb. As a control, some of the measurements are made with a germanium bolometer with a uniformly deposited germanium film. Figure 2 shows the construction of the bolometer detectors. The schematic circuits for the measurements with the bolometers are shown in Figs. 3 and 4; these circuits are dc voltage dividers. Here R_A is an auxiliary resistance used to detect the voltage across the bolometer. The circuit parameters must satisfy the relation $\Delta R_b/(R_b + R_A) \ll 1$. When there is a constant current through the bolometer, the energy fed to the plate is related to quantities which can be measured directly by

$$W = mc\frac{\Delta V_b}{a V_b}\frac{1}{\kappa}, \tag{1}$$

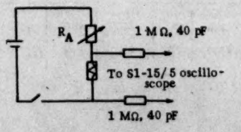

Fig. 3. Power circuit for the bismuth bolometer.

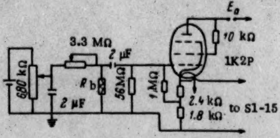

Fig. 4. Circuit of the power supply and cathode follower for the germanium bolometer.

where W is the energy, m is the mass of the aluminum substrate, c is the heat capacity of Al, α is the temperature coefficient, ΔV_b is the detected change in the bolometer voltage, V_b is the bias voltage, and $\varkappa$ is the absorptance. To detect small changes ΔV_b corresponding to emission in the visible part of the spectrum, we use an S1-15/5 oscilloscope with a differential input. The noise level is considerably reduced when a voltage is applied to the bolometer. The bolometer and oscilloscope are at a floating potential; experience has shown that this arrangement reduces the interference in comparison with the arrangement in which the bolometer and oscilloscope are connected to the discharge chamber (to ground, or to a terminal of the discharge circuit).

Figure 5 shows a typical bolometer signal.

ABSORPTANCE OF THE BOLOMETER AND ITS CALIBRATION

As shown below, the radiative loss in a magnetoplasma compressor is due primarily to radiation in the vacuum-UV part of the spectrum. The absorptance for this radiation for various materials, including aluminum, is high.[4,5] Accordingly, the absorptance is essentially the same for blackened and unblackened bolometers. However, the question of the absorptance of an unblackened bolometer becomes important for energy measurements in the visible or near-UV region. All the measurements reported here are carried out with a blackened bolometer. The bismuth bolometer is blackened by sputtering a thin platinum wire in vacuum. The operation of the blackened bolometer is checked by comparing known signals, produced during the detection of the radiative energy from a flash bulb before and after blackening.

Since the detecting surface of the high-resistance germanium bolometer is thick (100 μ), it turns out to be sufficient to blacken the bolometer with ordinary lampblack. The blackening increases the bolometer signal corresponding to the flashbulb by a factor of 6.8, indicating an absorptance of 15% for the unblackened bolometer. The blackening does not affect the bolometer characteristics, since the blackening process itself is monitored by measuring the energy radiated by the flashbulb.

The absolute calibration of the bolometer is carried out on an IKT-1M apparatus, designed for measuring pulsed light energy. As a result of all the measurements, we find a sensitivity of 6.1 V/J · cm² for a germanium bolometer 1 cm in diameter. The error in the calibration of the bolometer is less than 15%; it consists of the error in the operation of the IKT-1M (10%) and the errors in reading the signals. Repeated measurement of the radiative energy of the compressor under the same conditions reveals a scatter in the values of this energy from discharge to discharge; in certain cases this scatter reaches 40%, but it is generally within 20%. These measurements therefore have errors less than 35%.

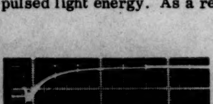

Fig. 5. Typical bolometer signal.

INSERTION OF THE BOLOMETER INTO THE VACUUM CHAMBER

Figure 6 gives a general idea of the layout of the measurement circuit. The vertical grooves in the flange of the MK-10 make photography possible at five points along the radius above the compressor axis and at five points below the axis. The collimating tube, with a special adapter for the vacuum gasket, is moved along the radius in 1 cm steps. In a qualitative experimental test to ensure that there is no significant absorption of radiation from the focal region by the residual gas in the vacuum chamber, we carry out special measurements along the longitudinal axis of the compressor, through a diverter in the cathode while injecting hydrogen from eight thermal valves. During the injection of the working gas (hydrogen) from the valves, the residual pressure in the chamber is 10^{-5} torr. At this pressure the radiation is not absorbed over 60 cm, especially since most of the energy is carried by ionized impurity atoms. A preliminary filling of the discharge region with hydrogen from the distributing ring of valves also has no effect on the absorption.

Although there is a time of 250 μsec between ignition pulses in the discharge circuit of the valve bank and the discharge circuit of the main bank, so gas can fill the interelectrode region, the gas cannot reach the cathode cavity through which the observation is carried out, since the distributing ring is behind the diverter (the aperture in the cathode) and there are no reflecting surfaces in front on it. However, during the discharge some of the ions are deflected from the cathode region to the diverter because of the high pressure at the focus of the discharge. Since the cathode aperture and the bolometer are quite far apart (60 cm), most of these ions recombine at the cathode and

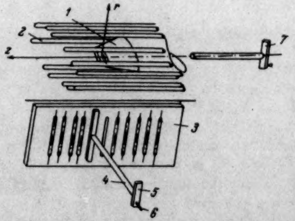

Fig. 6. Experimental arrangement. 1) Cathode; 2) anode rods; 3) flange; 4) collimator; 5) vacuum-sealed bolometer holder; 6) leadout plug (to oscilloscope); 7) bolometer position for observation along the longitudinal axis.

return to the cavity as neutrals. In this case the absorption is not resonant and is even weaker. It is primarily heavy impurity ions which are drawn from the cathode film into the diverter.

Since the plasma jet in the MK-10 has a strongly expressed directed velocity, the detection direction is chosen either along the flow direction or perpendicular to it to prevent charged and neutral particles from reaching the bolometer. In addition, we use a magnetic filter with a field of H = 80 Oe to prevent the return of the ions.

The level of radiated energy corresponding to the admission of H_2 is compared with that corresponding to a preliminary H_2 pressure in the vacuum chamber of 0.2 torr. The oscillograms of the current and voltage under these circumstances are most similar. This comparison shows that the bolometer detects 22% more energy in the case of hydrogen admission than in the case of a preliminary filling. This result is indirect evidence that the residual H_2 in the path to the bolometer absorbs some of the radiation. We do not observe an effect of the magnetic filter beyong the scatter in values for the individual discharges. In view of the detection directions selected, the existence of the gas filter, and the removal of the bolometer to a remote point we can conclude that the bolometer detects the energy of the electromagnetic radiation.

MEASUREMENTS OF THE ENERGY OF THE ELECTROMAGNETIC RADIATION

Both the MK-10 itself and the discharge occurring in it are cylindrically symmetric, so when a suitable arrangement is used for inserting the bolometer into the vacuum chamber, measurements can be carried out at various cross sections and at various radial positions. Then, after an Abel inversion, we find results showing how much electromagnetic energy $W_1(r, z)$ is evolved at a given radius from 1 cm^3 in various cross sections. In the Abel inversion it is assumed that no radiation is absorbed in the plasma. For the central zone of the discharge for operation with either air or hydrogen, this condition is not satisfied completely, so the height of the peak in the resulting $W_1(r, z)$ distributions can be slightly low. However, we expect that this difference is not very pronounced, since a large part of the energy from the central zone is due to doubly charged OIII and NIII ions and triply charged OIV and NIV ions, for which the absorption is slighter than for OII and NII ions because of the small dimensions of the zone (D ≤ 1 cm).

In preliminary measurements through glass and quartz filters it is found that most of the radiated energy is evolved in the vacuum-UV part of the spectrum. For the compression zone we construct functional dependences of the radiated energy W_c on the voltage to which the discharge bank is charged, under the assumption of a point source. The radiation is detected from a zone D = 3 cm in diameter through a tube 2 cm in diameter at the position r = 0, z = 3 (Fig. 6). These functional dependences are shown in Fig. 7 for working-gas (air) pressures of $P_1 = 0.2$, $P_2 = 1$, and $P_3 = 3$ torr and for a hydrogen pressure of P = 0.2 torr. The rapid increase in W_c with increasing bank voltage is interesting. In a discharge with P = 1 torr (air), a 1-kV increase in the bank voltage increases the radiated energy by a factor of 2.4. This result shows that the function $W_c(U)$ increases more rapidly than the third power of the voltage but more slowly than the fourth power. An analogous increase in the energy of the short-wave radiation is detected through foils in measurements with a photomultiplier. The radiated energy from the compression zone can be described as a cubic function of the bank voltage for working-gas (air) pressures of P = 0.2 and 3 torr:

$$W_c = 10U^3,$$

where W_c is in joules and U is in kilovolts.

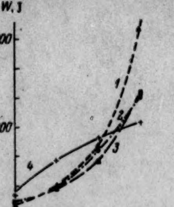

Fig. 7. Energy radiated from the compression zone as a function of the bank voltage. P_{air}, torr: 1) 0.2; 2) 1; 3) 3. p_{H_2} = 0.2 torr.

Figure 8 shows the total radiated energy of the pressure as a function of the voltage for working-gas (air) pressures of $P_1 = 0.2$ (curve 1), $P_2 = 1$ (2), and $P_3 = 5$ torr (3). The total radiated energy is detected by a bolometer mounted on an observation window of the compressor in such a manner that radiation from the entire discharge volume can strike it. The total radiated energy increases rapidly with increasing bank voltage and with decreasing hydrogen pressure; the same is true of the radiated energy of an air plasma. For working gases of air and hydrogen at P = 0.1 torr, the function $W_0(u)$ can be described by

$$W_0^{air} \approx 240U^3,$$

$$W_0^{hyd} \approx 390U^3.$$

At P = 1 torr for both gases the total radiated energy is a cubic function of the bank voltage:

$$W_0 \simeq 34U^3.$$

The radiated energy for a hydrogen plasma is higher than that in the case of an air plasma at low pressures because of the impurities in the hydrogen plasma and its higher temperature.

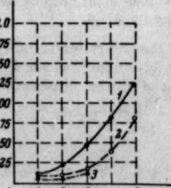

Fig. 8. Total energy radiated by the compressor as a function of the bank voltage. P_{air}, torr: 1) 0.2; 2) 1; 3) 5.

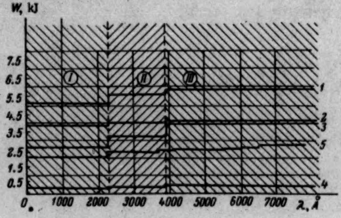

Fig. 9. Total radiated energy in various spectral ranges: I) W_{vac}; II) $W_{vac} + W_{nr-UV}$; III) $W_{vac} + W_{nr-UV} + W_{vis}$. For III, the values of U(kV) and P (torr), respectively, are: 1) 5, 0.1; 2) 5, 1; 3) 4, 0.1; 4) 1, 0.1; 5) 3, 0.1.

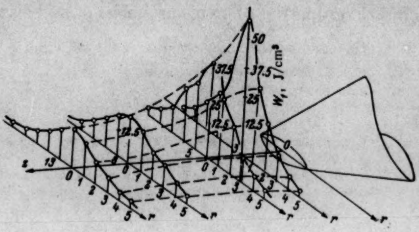

Fig. 10. Distribution of the radiated-energy density for the case of pulsed injection of hydrogen.

We also carry out bolometer measurements of the radiated energy integrated over the volume of the MK-10 in the visible and near-UV parts of the spectrum. The visible region is singled out by a glass filter, while the visible and near-UV are singled out by a quartz filter. The filters are placed in front of the bolometer, at its vacuum connection to the discharge chamber. Detection of the spectral lines on a DFS-13 apparatus shows that the quartz filter which we use transmits radiation up to 2300 Å. The radiative energies of the air plasma for three spectral regions ($\lambda \approx$ 0-2300, 2300-3800, and 3800-7000 Å) and for various operating conditions of the compressor are shown by the stepped lines in Fig. 9. The ratio W_{vis}/W_0 varied from 2% to 27% over the various operating conditions of the compressor in both air and hydrogen. Lower values of this ratio are found for lower working pressures in the range studied (0.1-5 torr).

We turn now to the spatial distribution of the density of the total radiated energy W_1 (joules per cubic centimeter) along the longitudinal axis and along the radius for the case of pulsed injection of hydrogen (U = 5 kV). In this case the discharge has the best spectral purity. The hydrogen pressure in the interelectrode gap before the beginning of the discharge, with an injection time of $\tau = 250$ μsec, is $\leqslant 1$ torr. The residual pressure in the chamber is $5 \cdot 10^{-5}$ torr. Under these conditions, according to spectral studies with a DFS-6 spectrograph (the vacuum region), the emission lines of ions from the compression zone (MK-10) correspond to the ions CIV, CIII, OIII, SiIV, SiIII, etc. All these elements are impurities, and the plasma is optically thin for the emission lines of these ions. Figure 10 shows the $W_1(r, z)$ distribution obtained by an Abel inversion of the experimental data. The density of the radiated energy at the maximum is $W_1(r = 0, z = 3) = 58$ J/cm³. The half-width of the $W_1(r)$ distribution for z = 3 cm is 2.5 cm. Summation of the energy over the discharge zone ($0 \leq z \leq 13$ cm) yields 8200 J, or about 50% of the energy supplied to the discharge. Local measurements of the radiated energy are also carried out for other conditions. We find that the height of the peaks in the $W_1(r)$ distributions decreases while the half-widths increase with increasing working-gas pressure.

All our measurements of the energy of the electromagnetic radiation, both in the vacuum region and in the visible and near-UV regions, show that W is a strong function of the voltage on the discharge bank and of the working-gas pressure. The total energy radiated by the plasma in the MK-10 compressor (for a bank energy of 30 kJ) is 30%-50% of the energy supplied to the discharge, $\int iudt$, depending on the discharge conditions.

In conclusion the authors thank P. E. Kovrov, Yu. S. Maksimov, L. G. Tokarev, and D. A. Shcheglov for assistance in this work.

(Submitted January 11, 1973)
Zh. Tekh. Fiz., 44, 355-363 (February 1974)

An experimental study has been made of an electrodeless discharge excited by a sinusoidal 50-kHz voltage in a plane glass cell filled with argon, neon, xenon, or a mixture of these gases at a pressures 1-50 torr. The potentials at which this discharge is ignited and quenched have been measured. The charge transferred to the external circuit over a half-period of the supply voltage has been measured. The results are used in an analysis of the bistable nature of this discharge which is of interest in connection with the development of ac plasma display devices. The description of the bistable nature of the discharge on the basis of the deposited charge is not complete; in particular, this description does not explain the change in the discharge diameter which is observed experimentally in the bistable region.

INTRODUCTION

An intense effort is currently being devoted to the development of ac plasma display devices[1-7] whose parameters are governed by the physical properties of an electrodeless pulsating discharge. According to ref. 8 a discharge of this type is an ac discharge, whose basic parameters change considerably over a half-period of the supply voltage. In the limiting case, the pulsed discharge can be thought of as a periodic train of short pulsed discharges.

A property of pulsed electrodeless discharges which is important for use in plasma display devices is the bistable nature of the operation. By definition, a pulsed discharge is bistable over a certain range of the applied alternating voltage (the bistable range) if it is capable of maintaining one of two different initial states for an infinitely long time in this range; in one state there is a discharge, while in the other there is not.

Several workers[1-7] believe that the bistable nature of this discharge results from an additional electric field which is produced in the gas by charges deposited on the dielectric walls during the breakdown. This opinion is based on the results of a study of a low-frequency electrodeless discharge.[9-11]

However, the results of refs. 9-11 may not be applicable to plasma display devices because of the qualitative difference between low-frequency discharges and the discharge in a display device, which occurs at a frequency of ~ 150 kHz. The difference results from the fact that the characteristic time for the deposition of charge on the dielectric walls is equal roughly to the transit time of the ions through the gas-filled gap (~ 10^{-4} sec), which is much longer than the time interval between two successive discharges in plasma display devices. In low-frequency discharges, we find the opposite situation. Since this time interval is short, the plasma produced during a brief pulsed discharge in a plasma display device may not have vanished completely by the beginning of the succeeding pulsed discharge. Accordingly, ionized, excited, and metastable atoms can exist in the gas-filled volume of the display device before the succeeding breakdown; these atoms would facilitate this succeeding breakdown and thereby influence the bistable nature of the discharge.

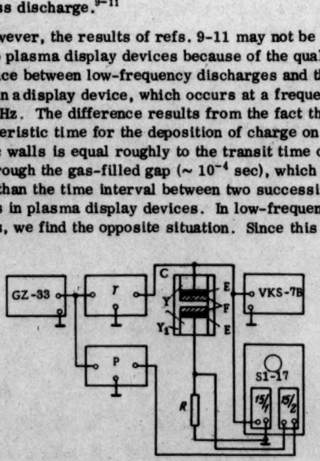

Fig. 1. Block diagram of the experimental apparatus.

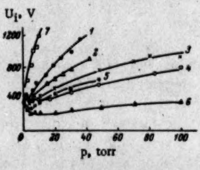

Fig. 2. Potential at which the discharge is ignited in a cell without the additional glass pieces, U_i, as a function of the gas pressure p. 1) Xe; 2) 50% Ne + 50% Xe; 3) 85% Ne + 15% Xe; 4) 95% Ne + 5% Xe; 5) Ar; 6) Ne; 7) air.

Accordingly, several mechanisms leading to a bistable nature can operate in plasma display devices. To determine the relative importance of these mechanisms it is necessary to study the physical properties of pulsating electrodeless discharges at high frequencies. The basic purpose of the work described below is to determine the role of deposited electric charge in the mechanism responsible for the bistable nature of such a discharge.

EXPERIMENTAL PROCEDURE

The experiments are carried out on the apparatus shown in Fig. 1. The electrodeless pulsed discharge is excited in cell C, which consists of two glass cylinders Y with flat ends F (50 mm in diameter), sealed in a third cylinder Y_1 in such a way that the flat ends F are parallel. Each of the flat glass pieces F is 5 mm thick, and they are 5 mm apart. Circular metal electrodes E, with diameter slightly less than 50 mm, are pressed tightly against the outside of glass pieces F. In several of the experiments additional glass pieces 5 mm thick with diameter equal to that of electrode E are inserted between electrodes E and pieces F. The cell is processed by standard vacuum techniques; after it is evacuated to ~ 10^{-5} torr it is filled with the appropriate gas. In these experiments we use argon, neon, "pure" xenon, and mixtures of these gases. The gas pressure in the cell is varied over the range 1-50 torr, so that the parameters of the experimental cell are equivalent to those of the cell of a plasma display device as follows from the appropriate similarity law.

The experiments are carried out with a sinusoidal voltage at a frequency of 50 kHz. The regulated voltage source is a standard GZ-33 generator; the output voltage is fed through step-up resonance autotransformer T (with an output resistance of ~ 100 kΩ) and through a small resistance of R ~ 300 Ω to electrodes E. The voltage beyond the autotransformer is measured by a VKS-7B voltmeter and the shape is monitored on an S1-17 oscilloscope.

The ignition potential U_i and the quenching potential U_q are measured for the electrodeless pulsed discharge in the cell; the current pulses produced in the external circuit of cell C during the breakdown are also measured. The ignition and quenching of the discharge are determined visually on the basis of the associated glow and are also determined from the appearance and vanishing of the current pulses. In several of the experiments we measure the ignition potentials between nickel electrodes directly in the gas; these electrodes are 5 mm apart. Significantly, no appreciable shape distortion of the supply voltage is observed during breakdown in any of the cases studied. The current pulses flowing in the external circuit of the cell are inferred from the voltage pulses across a resistance of R = 300 Ω. These voltage pulses are fed to one input of an S1-15/2 differential amplifier in the S1-17 oscilloscope. A sinusoidal voltage is fed through phase shifter P to the other input of this amplifier and used to balance the sinusoidal voltage produced across resistance R by the capacitive current.

EXPERIMENTAL RESULTS

Figure 2 shows the ignition potential of the electrodeless discharge, U_i, as a function of the gas pressure p for various conditions. These functional relations are obtained in cell C without the additional glass pieces, under conditions such that the discharge glow covers nearly the entire inner surface of flat glass pieces F during breakdown (Fig. 1). The functional relations between the quenching potential U_q and p are similar.

We see from Fig. 2 that the functional dependence of U_i on p display minima characteristic of Paschen curves.

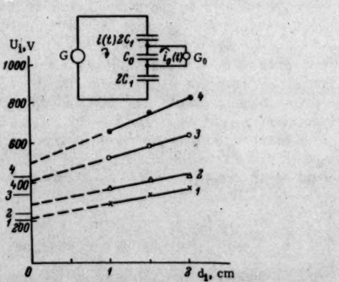

Fig. 3. Ignition potential of a discharge in argon, U_i, as a function of the thickness of the glass plates d_1 for various pressures. p, torr: 1) 5; 2) 10; 3) 30; 4) 50. The equivalent circuit of the discharge cell is shown at the top.

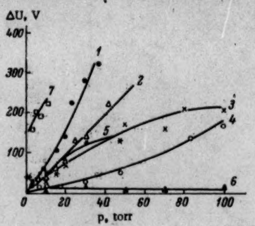

Fig. 4. Bistable range of the discharge ΔU, as a function of the gas pressure p. The notation is the same as in Fig. 2.

However, it should be noted that the quantities U_i and U_q are functions not only of the nature and pressure of the gas filling the cell, but also of the total thickness d_1 of the glass pieces F, since part of the sinusoidal voltage applied across electrodes E is applied across these glass pieces. That this is true can be seen from Fig. 3, which shows illustrative functional dependences of U_i on d_1 for various argon pressures. Similar functional relations are obtained for the other gases. We see from Fig. 3 that the functional dependence of U_i on d_1 is described by straight lines; extrapolation of these lines to the ordinate axis yields the "true" ignition potentials of the electrodeless discharge, $U_{i.0}$. In similar fashion we can determine the "true" quenching potentials for the discharge.

The markers on the ordinate axis in this figure show the ignition potentials for discharges in argon between nickel electrodes measured under the conditions corresponding to lines 1-4. We see from Fig. 3 that these potentials differ negligibly from the "true" ignition potentials $U_{i.0}$; furthermore, they are essentially equal to the breakdown potentials for argon in a homogeneous, fixed electric field, as reported in, e.g., ref. 12.

From the measured values of U_i and U_q we calculate the bistable range $\Delta U = U_i - U_q$. Figure 4 shows the resulting functional dependence of ΔU on the gas pressure. Comparison of Figs. 4 and 2 shows that there is a correlation between ΔU and U_i: As U_i increases, so does ΔU. We see from Fig. 4 that the maximum value of ΔU is found in Xe (curve 1), while the discharge in Ne has essentially no bistable range (curve 6).

The current pulses in the external circuit of the cell during the breakdown are approximately triangular with a half-width of about 3 μsec, much shorter than the half-period of the supply voltage, i.e., this discharge is a pulsating discharge. We should add that when the cell is filled with neon current pulses cannot be detected.

Numerical integration of the current pulses reveals the charge transferred in the external circuit of the cell during a single breakdown, ΔQ. We find ΔQ as a function of various parameters. Figure 4 shows ΔQ as a function of the sinusoidal voltage U applied to electrodes E, for argon with three thicknesses d_1 of the flat glass pieces F. The arrows on the abscissa in Fig. 5a show the quenching potentials for this discharge; the corresponding breakdown potentials for the discharge are shown by arrows near the lines. The "true" ignition potentials and quenching potentials for the discharge ($U_{i.0}$ and $U_{q.0}$), determined from the functional dependence of U_i and U_q on d_1, are 400

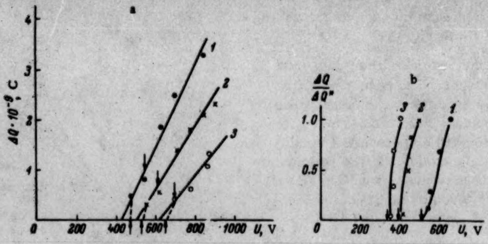

Fig. 5. a: Charge transferred in the external circuit during a single pulse, ΔQ, as a function of the amplitude of the applied voltage, U, for various thicknesses of the flat glass pieces d_1. Argon, 30 torr. d_1, cm: 1) 1; 2) 1.5; 3) 2.0. b: Behavior of the quantity ΔQ/ΔQ* in the bistable region of the discharge. Argon. p, torr: 1) 50; 2) 30; 3) 10.

and 300 V, respectively, for the conditions of Fig. 5a.

We see from Fig. 5a that the functional dependence of ΔQ on U is described by a straight line; the slopes of lines 1-3 are 11.4, 7.7, and 4.3 pF, respectively.

The functional dependences of ΔQ on U are measured at various argon pressures over the range 1-50 torr in the cell; the results are essentially the same as those in Fig. 5a over the entire range of the applied sinusoidal voltage, except in the bistable region.

Figure 5b shows examples of the behavior of ΔQ, in relative units, in the bistable region; we see that as U decreases in this region there is a sharp decrease in ΔQ (ΔQ* is the amount of charge transferred in the external circuit at the ignition potential). We also note a simultaneous decrease in the cross-sectional area of the discharge: The discharge contracts toward its center. We also note that near the ignition potentials shown by arrows in Fig. 5b the values of ΔQ are much smaller than ΔQ*.

It is interesting to examine the relation between the length of the bistable range ΔU and the charge ΔQ*; functional dependences of ΔQ* on ΔU are shown in Fig. 6 for the same cell without the additional glass pieces (d_1 = 1 cm). There is no information for neon in this figure because the corresponding values of ΔQ and ΔQ* are extremely small.

Figure 7 shows the functional dependence of ΔQ* on ΔU obtained in an argon-filled cell at various values of d_1. We see from Figs. 6 and 7 that the functional dependences of ΔQ* on ΔU are described by straight lines, whose slopes are functions of d_1 and of the nature of the gas filling the cell. Table 1 shows the slopes of the lines, $d\Delta Q^*/(d\Delta U)$, calculated from the data in Figs. 6 and 7. The changes in ΔU (and thus ΔQ*) along the lines in Figs. 6 and 7 were caused by changing the pressure p of the gas filling the cell (Fig. 4).

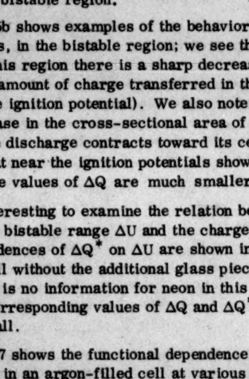

Fig. 6. Charge transferred in the external circuit of the cell during a single pulse at the ignition potential, ΔQ*, as a function of the length of the bistable range ΔU. The notation is the same as in Fig. 2.

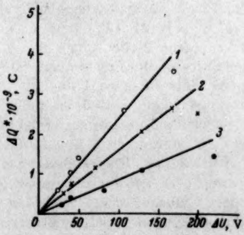

Fig. 7. Functional dependence of ΔQ* on ΔU in an argon filled cell for various glass thicknesses. d_1, cm: 1) 1.0; 2) 1.5; 3) 2.0.

DISCUSSION OF RESULTS

The equivalent circuit of the electrodeless discharge according to refs. 5 and 9 is shown at the top in Fig. 3, where C_0 is the capacitance of the capacitor corresponding to the gas-filled gap of the cell of width d_0; $2C_1$ is the capacitance of the capacitor formed by the inner surface of the glass and electrode E; G is an ideal supply-voltage generator; and G_0 is the generator representing the charging of the inner glass surfaces by the discharge current. Special measurements show that under these experimental conditions $C_0 = 4.25$ pF and $C_1 = 17.2/n$ pF, where n is the total number of glass pieces of thickness d_1 separating electrodes E from the discharge gap. According to the equivalent circuit, we have

$$U_0=\frac{C_1}{C_1+C_0}U=\frac{1}{1+\frac{d_1}{\varepsilon d_0}}U, \qquad (1)$$

where U and U_0 are the alternating voltages applied to electrodes E and to the gas-filled gap, respectively.

A discharge occurs in the cell when U_0 reaches $U_{i.0}$; according to (1), U_i is described as a function of d_1 by

TABLE 1

Ar	4.5	10.0	0.45	Line *3*, Fig. 8

$$U_i = U_{i,0} + \frac{d_1}{\varepsilon d_0} U_{i,0}. \tag{2}$$

The data in Fig. 3 satisfy Eq. (2). The values of ε calculated from the slopes of lines 1-4 in this figure are 5.8, 6.8, 6.6, and 6.2, respectively, close to the value obtained from a comparison of C_0 and C_1: $\varepsilon \sim 4$. On the basis of this result and the circumstance that there is no distortion of the applied voltage during the breakdown we conclude that the equivalent circuit in Fig. 3 is applicable under the present experimental conditions.

Since the functional dependence of U_i on the gas pressure p is described by Paschen curves, and since the values of $U_{i.0}$ are approximately equal to the breakdown potentials in a homogeneous, fixed electric field, we can assume that the mechanism for the gas breakdown in this discharge is approximately the same as that in a fixed electric field. Accordingly, in choosing gases or mixtures thereof for achieving a desired ignition potential for a pulsating electrodeless discharge we can, in a first approximation, use the results found in a study of breakdown in fixed electric fields.

Using the equivalent circuit in Fig. 3 we can write the following equations for the behavior of the voltage drop across the dielectric layers of the cell (ΔU_1) and across the gas-filled cavity (ΔU_0) during the time τ as currents $i_0(t)$ and $i(t)$ flow:

$$\Delta U_1(\tau) = \frac{1}{C_1}\int_0^\tau i(t)\,dt, \tag{3}$$

$$\Delta U_0(\tau) = \frac{1}{C_0}\int_0^\tau i(t)\,dt - \frac{1}{C_0}\int_0^\tau i_0(t)\,dt. \tag{4}$$

Since generator G is ideal, we can write, for any τ,

(5)

then using (4) we find

$$-\Delta U_0(\tau) = \frac{1}{C_1}\int_0^\tau i(t)\,dt. \tag{6}$$

On the other hand, if the charging of the inner glass surfaces is responsible for the bistable nature of the discharge, we can write, by analogy with refs. 3 and 4,

$$-\Delta U_0\left(\frac{T}{2}\right) = 2(U_0 - U_{q,0}), \tag{7}$$

where U_0 is the maximum (over a half-period) value of the external voltage applied to the inner gas-filled cavity of the cell, $U_{q.0}$ is the "true" quenching potential of the discharge in the inner cavity of the cell, and $\Delta U_0(T/2)$ is the change in the voltage drop in the gas-filled cell over the half-period of the supply voltage, T/2, which results from the charging. For a sinusoidal applied voltage, U_0 would be the peak value.

From Eqs. (1), (6), and (7) we find the charge transferred in the external circuit of the cell during half-period T/2, ΔQ, as a function of the peak value U of the sinusoidal voltage applied to electrodes E:

$$\Delta Q\left(\frac{T}{2}\right) = \int_0^{\frac{T}{2}} i(t)\,dt = \frac{2C_1^2}{C_1+C_0}U - 2C_1U_{q.0}. \tag{8}$$

Graphically, Eq. (8) is a straight line intersecting the U axis at a value U^* related to the "true" quenching potential $U_{q.0}$ by

$$U_{q.0} = \frac{C_1}{C_1+C_0}U^*. \tag{9}$$

The slope of line (8) is governed by the cell parameters, and its intersection with the abscissa, according to (9), is a function of both the cell parameters and the properties of the gas filling the inner cavity of the cell.

Table 2 shows the parameters $[\partial\Delta Q/(\partial U), U^*]$ for the lines in Fig. 5, the values of $U_{q.0}$ calculated from Eq. (9), and the values of the parameter $2C_1^2/(C_1 + C_0)$ for these experimental conditions. We see from this table that the slope of the lines in Fig. 5 is described well by Eq. (8) and that the values of $u_{q.0}$ calculated for various d_1 are essentially equal to the "true" quenching potential determined previously, equal to 300 V in this case. On the basis of this correspondence we can claim that at sufficiently high values of the applied voltage the discharge is cut off in each half-period by the deposited electric charge.

The deviation from the linear function (8) found in the bistable region (Fig. 5) means that the diameter of the discharge in this region (and thus the value of C_1) is not constant. This change in the discharge diameter probably occurs for the same reasons as that in a normal glow discharge.[13]

We turn now to data on the length of the range over which the discharge is bistable, ΔU, shown in Figs. 6 and 7. If the factor governing the bistable nature is the electric field of the deposited charge,[1-7] the discharge will be bistable if the voltage drop across the inner cavity of the cell, U_0, satisfies

$$U_{i,0} - \frac{1}{2}\Delta U_0 \leqslant U_0 \leqslant U_{i,0}, \tag{10}$$

TABLE 2

d_1, cm	$\frac{\partial\Delta Q}{\partial U}$, pF	$\frac{2C_1^2}{C_1+C_0}$, pF	U^*, V	U_{q0}, V
1.0	11.4	11.5	430	290
1.5	7.7	6.8	510	310
2.0	4.3	4.5	630	320

where ΔU_0 is the change in U_0 resulting from the deposition of charge ΔQ_0 over a single half-period at a voltage approximately equal to the quenching potential. From (1), (10), (7), and (8) we find an equation for ΔU:

$$\Delta U = \frac{1}{2}\frac{C_1 + C_0}{C_1}\Delta U_0 = \frac{C_1 + C_0}{2C_1^2}\int_0^{\frac{T}{2}} i(t)\,dt = \frac{C_1 + C_0}{2C_1^2}\Delta Q_0\left(\frac{T}{2}\right). \quad (11)$$

However, we can assume that ΔQ_0 and ΔQ^* are related by $\Delta Q_0 = k\Delta Q^*$, where k is an arbitrary number. Then Eq. (11) becomes

$$\Delta U = \frac{C_1 + C_0}{2C_1^2} k\Delta Q^*\left(\frac{T}{2}\right). \quad (12)$$

It follows from these arguments that confirmation of Eq. (11) or (12) could be taken as evidence that the discharge is bistable because of the electric field of the deposited charge.

Under the present experimental conditions it is more convenient to test Eq. (12), because of the change in the discharge diameter in the bistable region. As mentioned above, the functional dependence of ΔQ^* on ΔU is linear (Figs. 6 and 7). Accordingly, the discharge studied here obeys Eq. (12), and the value of k in this equation is constant for each gas or for each mixture. Further confirmation of Eq. (12) comes from the circumstance that the discharge in a cell filled with pure neon is not bistable and that there is extremely little deposited charge.

The values of k and of all the other parameters required to calculate k are shown in Table 2. We see from this table that $k > 1$ in several cases; when this is so, the charge deposited per unit area of the glass surface near the quenching potential must be larger by a factor of k than the corresponding amount of charge deposited at the ignition potential in order to explain the observed range of bistable behavior. However, according to ref. 5 a stable pulsating discharge cannot exist under this condition if the role of the current pulses is simply one of forming the deposited charge.

Accordingly, the description of the bistable behavior of the discharge on the basis of deposited charge is not complete. In particular, this description does not explain the change in the discharge diameter in the bistable region. Further research is required to determine the complete picture of the phenomena occurring in a pulsating electrodeless discharge at a high frequency.

CONCLUSION

This experimental study of a pulsating electrodeless discharge resulting from the application of a sinusoidal supply voltage at 50 kHz to a glass cell filled with argon, neon, xenon, or a mixture of these gases has revealed the following behavior.

1. The discharge occurs in the cell at levels of the sinusoidal voltage approximately equal to the breakdown potential in a homogeneous, fixed electric field. We can therefore assume that the mechanism for the gas breakdown in this discharge is approximately that for breakdown in a fixed electric field.

2. When the discharge is in the bistable region and the applied voltage is changed, a significant change occurs in the discharge diameter.

3. The description of the properties of the discharge in the bistable region on the basis of the effect of the electric field of the deposited charge is not complete.

In conclusion the authors thank N. D. Morgulis for his interest in this work, and Yu. N. Posypaiko and S. I. Demidenko for assistance in the experiments.

Narrow-band decimeter radiation from lightning

E. L. Kosarev and Yu. G. Serezhkin

Institute of Physical Problems,
Academy of Sciences of the USSR, Moscow

(Submitted May 28, 1973)
Zh. Tekh. Fiz., 44, 364-371 (February 1974)

Observations of narrow-band decimeter radiation from lightning are reported. The radiation power can reach 10^{-9}-10^{-8} W at the input of a spectrum analyzer and this corresponds to a spectral flux density of more than 10^{-12}-10^{-11} W/m^2 · Hz at a distance of 1 km from the lightning. In the range of time intervals 30-200 msec, the number of cases in which the radiation lasts longer than a time T is proportional to $1/T^2$. The maximum observed duration is 0.17 sec. The narrow-band radiation always occurs after streak lightning and the average delay time is 0.25 sec; the most probable delay time is 0.15 sec. The possible sources of the radiation and the connection between this radiation and ball lightning are discussed.

INTRODUCTION

In 1967 the present authors started a number of experiments designed to test the Kapitsa hypothesis regarding the electromagnetic nature of ball lightning[1] and showed[2-4] that streak lightning gives rise to microwave radiation with a continuous spectrum. The power is almost independent of frequency in the range $300 < f < 3000$ MHz and is of the order of 10^{-14} W/m^2, at a distance of the order of 1 km from the lightning.

The spectrum differs from the $1/f^2$ law, which holds for the longer wavelengths and which is obtained as a result of the spectral decomposition of the field produced by a lightning current pulse of the order of 10^{-4}-10^{-3} sec. This difference, and the presence of extended pulses of microwave radiation (up to 10^2 sec) even after the main phase of the discharge, indicate that the radiation is caused by plasma processes in an ionized discharge channel of streak lightning with a lifetime[5] of 0.1-1 sec.

The spectral measurements in refs. 2-4 were made by means of microwave receivers tuned to separate discrete frequencies and therefore the results really refer to the continuous radiation spectrum, which has the character of noise. However, it was found when the radiation was recorded simultaneously on various frequencies that the microwave radiation was sometimes different from noise (which is characterized by an identical time variation on the different frequencies).

From the point of view of the Kapitsa hypothesis it is particularly interesting to observe the coherent narrow-band radiation. For this purpose we have used decimeter range spectrum analyzers with a sweep time of less than 10^{-3} sec to record all the microwave radiation independently of its time of appearance. These instruments were in fact employed in the 1967 measurements. However, their low sensitivity ($\sim 10^{-9}$ W at the input) and their poor recording system (visual observation from a CRO screen) mean that the narrow-band radiation could not be observed reliably and so no discussion of this aspect of the work was given in the published papers.[2-4] A detailed study of the narrow-band structure became possible only after considerable improvement of the apparatus.

APPARATUS AND EXPERIMENTAL METHOD

A block diagram of the present experimental apparatus is given in Fig. 1. In order to increase the sensitivity of the spectrum analyzer, the input stage uses a traveling-wave tube with a gain of 25 dB and a noise figure of 10 dB. The I.F. amplifier is a U2-5 unit with bandwidth of 5 MHz at 100 MHz.

The spectrum analyzer works in the central part of the decimeter region. The choice of this range is dictated by the fact that the 1967 observations show that the narrow-band radiation is concentrated in this region. The sensitivity of the analyzer is better than 10^{-12} W for long monochromatic signals and 10^{-11} W for signals with length of the order of 10^{-5} sec. The sensitivity is determined by means of signals from radar units and by a standard generator technique involving comparison with a P5 measuring receiver and a D4 attenuator.

The heterodyne stage uses a backward wave tube, which is frequency-modulated by a 4 kHz sine wave. The same sinsusoidal voltage is employed as the line sweep on the television-type display. The received signals modulate the brightness on the screen. Thus the horizontal motion on the screen corresponds to the frequency sweep of the analyzer. The total sweep time is 125 μsec. Both the forward and reverse sweep of the spot across the screen are used for display.

There are no filters in the input to the analyzer to distinguish between the upper and lower sidebands of the received signal. The ambiguity is eliminated as follows. Monochromatic radiation in the 200 MHz band would, under the modulation conditions described here, be observed at two places on the screen and the frequency f could be determined uniquely. If a signal appears at only one place on the screen, it is possible to determine the sign in the

equation $f = f_h + f_{if}$ (f_h is the heterodyne frequency). However, it is not possible to reliably identify short signals (T ≲ 1 msec) in different parts of the screen and so the ambiguity cannot be completely eliminated.

The signals on the screen are recorded by an automatic RFK-5 camera in the following way. The camera operates with a normally open shutter. The brightness on the screen is adjusted so that in the absence of signals the film is not fogged in a time of the order of 1 min. The time scan of the received signals during this period is achieved by means of a continuous frame sweep 20 msec long corresponding to a velocity of 65 cm/sec on the film.

During a lightning discharge, the low-frequency electromagnetic radiation (2-60 kHz) is received on the loop antenna and after a delay of about 20 msec switches on the film movement mechanism. In order to get more or less constant film speed and to ensure continuous exposure, the grab mechanism, which usually controls the start–stop motion of the film, and the sectoral shutter, which periodically cuts off the light, are removed from the camera. The vertical film movement at 30 cm/sec is achieved by means of a toothed traction wheel. The radiation is recorded for about 1 sec after each lightning discharge.

In this way, two time sweeps are used simultaneously: a fast sweep (frame sweep on the television indicator) and a slow sweep (mechanical movement of the film). This double system permits time resolution of the short pulses of radiation and recording of the long-duration radiation over an extended period. However, there is one basic disadvantage: an uncertainty in the measurement of the pulse length over the range 0-30 msec. For pulses of longer duration, in which we are mainly interested, the uncertainty can be neglected.

The lightning signals were recorded during the summer of 1972 in the Lenin Hills, Moscow. The method is as follows. When a storm approaches to within a distance of 10-15 km the system is switched on automatically or manually. In addition to the spectrum analyzer and recorder, the system also includes a 100 MHz receiver for recording the storm intensity on a pen chart and a tape recorder for the thunder so that the distance to the lightning can be determined. The various recordings are aligned by means of time marks. The spectrum analyzer uses the same disk–cone antenna as in the previous experiments;[2-4] this is designed to detect radiation with the electric field polarized vertically. The operation and sensitivity of the analyzer are monitored before and during the storms by means of signals from radar installations.

The maximum time for continuous automatic recording is 1.5 hours. If another storm approaches the station, the system is again switched on automatically or manually and the measurements continue until the storm is ended.

OBSERVATIONAL RESULTS

Measurements with the total system have been carried out during eight storms from July 8 to September 26, 1972. The best signals were recorded during the storm of the night 24-25 August; this was the first storm after a heat wave which lasted almost two months in Moscow.

Figure 2 shows an example of a recording of the lightning on August 24 at 23^{h}54'32" (the distance to the lightning is 6-8 km). The radiation pulse is about 10 msec long and has a continuous spectrum over the given range with a maximum at the higher frequencies. The two vertical lines to the left at the bottom, formed by a succession of dots, are the radar signals. The lines on the right are the same signals observed at the image frequency. Continuous-spectrum radiation similar to that shown in Fig. 2 has been studied in detail in our previous papers.[2-4]

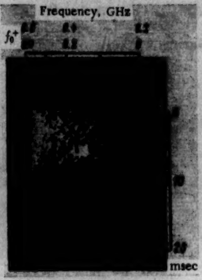

Fig. 2. A pulse of wide-band radiation from lightning. Discharge August 24, 1972, 23^{h}54'32". The three vertical lines formed by a series of dots are radar signals.

At the peak of this storm, from 21^{h}30' to 22^h, radiation with a discrete spectrum is observed clearly during the initial stages. An example of this non-noise radiation is given in Fig. 3 (21^{h}57'58", distance about 5 km). The same radar signals as in Fig. 2 can be seen in the upper part of the picture (which is obtained by exposure on a stationary film). The narrow-band radiation, which is clearly seen in the middle of the picture, appears some 40 msec after the lightning discharge.

This radiation consists of two intense pulses, each about 5 msec long,$^{1)}$ followed by a series of weaker pulses 20-30 msec long, which cannot be seen on the print but are discernible on the film. It is clear from the photograph that the radiation differs from normal radar signals both in length and in frequency.

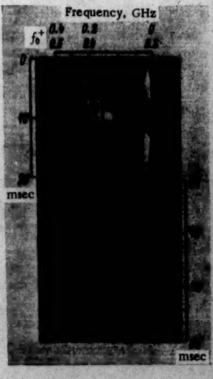

Fig. 3. Narrow-band radiation from lightning. Discharge August 24, 1972. 21^{h}57'58".

The observed discrete-spectrum radiation is not a result of direct low-frequency induction in the measuring apparatus, since such induced signals could not have a frequency exactly equal to the line-sweep frequency of the display unit. The connection between the observed radiation and lightning is further proved by the fact that no case of such radiation has been observed during control measurements in the autumn after the end of the storm season.[2)] Thus the narrow-band microwave pulses are in fact emitted during discharges of streak lightning.

Discrete-spectrum radiation has been observed 39 times during the storm of August 24, 1972. The results of a statistical analysis of the radiation parameters are given below. A rough estimate of the power is made by comparison with the radar signals and the continuous-spectrum radiation and gives a value of 10^{-9}-10^{-8} W. In order to determine the spectral density of the radiation it is necessary to know the bandwith. The actual value of this bandwidth was not measured but it seems to be considerably narrower than that of the radar signals. Thus, only the lower limit of the spectral density for the discrete-spectrum radiation can be given; it is 10^{-12}-10^{-11} W/m^2 · Hz at a distance of 1 km from the lightning. This value is at least two orders of magnitude greater than the density for the continuous-spectrum radiation as measured in our earlier work.[2-4]

The frequencies of all the discrete-frequency radiation are different from the radar frequencies f_1 and f_2. Figure 4 shows the frequency distribution averaged over each 10 MHz interval. Owing to the comparatively small number of observations (N = 39) and to the possible errors in the measurement of the short-duration radiation, Fig. 4 conveys only the important feature of the distribution, which is the presence of two groups: a more intense one on the left and a less intense one on the right.

The observed frequency distribution is in qualitative agreement with the results of preliminary measurements made in Armenia during 1967 with apparatus having a smaller resolving power. Since the observing conditions and the apparatus were quite different in 1967 and 1972, the similarity of the observed frequency distribution is strong evidence that the narrow-band radiation is in fact connected with lightning and not with induced voltages or equipment effects.

We now turn to the time characteristics of the narrow-band radiation. Figure 5 gives the accumulative distribution of the number of cases n when the radiation lasts for a time $\Delta t > T$ and the corresponding probability P = n/N. The observed distribution is closely approximated by the expression

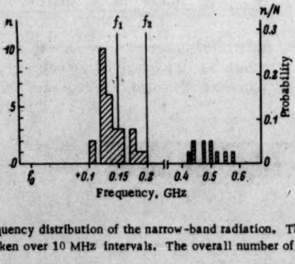

Fig. 4. Frequency distribution of the narrow-band radiation. The average has been taken over 10 MHz intervals. The overall number of observations is 39.

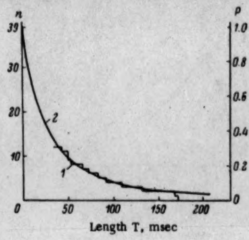

Fig. 5. Distribution in duration of the narrow-band radiation. The abscissa shows the duration T and the ordinate gives the number of pulses with a duration greater than T. 1) Observed distribution; 2) approximating expression (1) with τ = 50 msec.

$$P(\Delta t > T) = \frac{2}{\tau}\int_{T}^{\infty}\frac{d(\Delta t)}{\left(1+\frac{\Delta t}{\tau}\right)^{3}} = \frac{1}{\left(1+\frac{T}{\tau}\right)^{2}}, \qquad (1)$$

in which the parameter τ is equal to the average duration of the narrow-band radiation pulses:

$$\langle\Delta t\rangle = \frac{2}{\tau}\int_{0}^{\infty}\frac{\Delta t\, d(dt)}{\left(1+\frac{\Delta t}{\tau}\right)^{3}} = \tau.$$

The best agreement with the observations is obtained with τ = 50 msec. We may point out that the maximum length of the observed narrow-band radiation is 170 msec and this is an order of magnitude greater than the corresponding figure for the wide-band radiation observed in refs. 3 and 4 (10 msec).

Another characteristic of the narrow-band radiation is that it occurs with a considerable delay after the beginning of the streak lightning discharge. Figure 6 gives the cumulative distribution of the number of pulses n with a time of appearance $t > t_0$. The observed distribution of n = NP can be well approximated by a gamma distribution, for which

$$P(t > t_0) = \frac{\frac{\alpha}{\Gamma(\alpha)}}{\tau_0}\int_{t_0}^{\infty}\left(\frac{\alpha t}{\tau_0}\right)^{\alpha-1}\exp\left(-\frac{\alpha t}{\tau_0}\right)dt. \qquad (2)$$

The parameter τ_0 in this expression, equal to the average delay of the narrow-band radiation

$$\langle t\rangle = \frac{\frac{\alpha}{\Gamma(\alpha)}}{\tau_0}\int_{0}^{\infty} t\left(\frac{\alpha t}{\tau_0}\right)^{\alpha-1}\exp\left(-\frac{\alpha t}{\tau_0}\right)dt = \tau_0,$$

and the parameter α are determined by making the best fit between (2) and the observed results; these parameters turn out to be given by τ_0 = 0.25 sec and α = 2.56. Figure 6 also gives the density corresponding to the gamma dis-

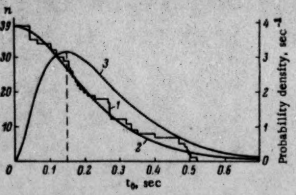

Fig. 6. Distribution of the time delay of the narrow-band radiation after the beginning of the streak lightning discharge. 1) Observed distribution of the number of pulses with a time of appearance greater than t; 2) gamma distribution approximation (2) with $\tau_0 = 0.25$ sec and $\alpha = 2.56$; 3) density of the approximating gamma distribution.

tribution (curve 3). It can be seen that the most probable delay is equal to about 0.15 sec. The maximum observed delay is 0.52 sec.

The most interesting feature of the narrow-band radiation is that it is subjected to a periodic amplitude modulation with a period of 2-5 msec. Figure 7 shows a recording of radiation lasting for 170 msec. This is the longest case of narrow-band radiation that we have observed. The periodic amplitude modulation is quite clear, especially in the central part of the recording. It should be noted that such obvious modulation is not observed on all occasions but only with the long-duration radiation. In the majority of cases, only a few pulses are seen (Fig. 3, for example).

POSSIBLE SOURCES OF THE NARROW-BAND RADIATION

Since the narrow-band radiation lasts for quite a long time (50 msec on average, with not less than 5% of cases having length greater than 150 msec), and appears with a considerable time delay after the start of the streak lightning discharge (average 0.25 sec, most probable value 0.15 sec), we can draw the following definite conclusion: The source of the radiation is the ionized channel of the streak lightning. The times in fact correspond to the lifetime of the channel as determined both by optical measurements of the overall duration of the lightning flash and by electrical measurements of the interpulse currents. The relevant data are given in Uman.[5]

For the less intense group of narrow-band radiation in the upper part of the range (Fig. 4) we can define a more definite source. It seems that about half the signals in this group arise as a result of scattering of the continuous radiation from a broadcast station by the ionized channel. In the absence of any storm, no signals are observed in this range. But sometimes (independently of any storm), we observe an intense broadcast signal which is continuous in time and has a frequency which corresponds to that of the narrow-band signals of the lightning radiation in this range.

The amplitude of the scattered field depends on both the parameters of the lightning channel (that is, mainly on the maximum electron density and the variation of density with radius) and on the relative positions of the transmitter, channel, and receiver. In view of the approximate nature of our power measurements, we cannot compare our observations with even the simplest theory of microwave scattering by a lightning channel.[6] If the accuracy of the measurements is increased, this observation of scattered radiation could become an effective method of studying lightning channels.

As regards the more intense group of radiation in Fig. 4, it is very probable that the primary source of radiation is the streak lightning channel itself since in this region we do not observe any signals which are not related to the lightning. A comparison of the narrow-band radiation spectra obtained in 1967 and 1972 leads to the same conclusion.

If this conclusion is accepted, we can propose the following mechanism for the generation of the radiation. A ionized discharge channel from streak lightning with a diameter of the order of 10 cm, an electron density of 10^{16}-10^{18} cm^{-3}, and a temperature of 10,000-30,000° can be represented as a waveguide for all waves up to plasma wavelength (which here corresponds to the submillimeter zone). Since strong electric fields (up to 10,000-20,000 V/m) are observed during storms and also high directive electron fluxes, the electron distribution function is doubtless very far from an equilibrium one. Under these conditions, amplifications of the magnetic bremsstrahlung and Cerenkov radiation of the discharge electrons are possible in the magnetic field of the lightning at wavelengths corresponding to transverse plasma resonances; such effects have been observed with radiowave scattering at meteor trails and in experiments with a laboratory plasma.[7,8] The amplitude modulation could arise as a result of mode competition as in lasers and through interference of the coherent radiation from different parts of the diffusion expanding channel.

CONCLUSION

We have discovered a hitherto unknown long-duration narrow-band microwave radiation from lightning. The maximum observed length is 0.17 sec. The radiation appears some 0.1-0.4 sec after the leader stage of the lightning discharge and is emitted by the ionized discharge channel.

The data are insufficient to be able to state definitely that this radiation is the cause of the ball lightning discussed by Kapitsa. Although the frequency and length of

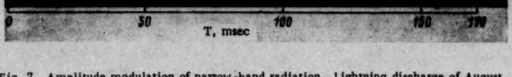

Fig. 7. Amplitude modulation of narrow-band radiation. Lightning discharge of August 24, 1972, $21^h54'42"$; length of the radiation pulse is 170 msec.

the radiation pulse correspond to the value in Kapitsa's hypothesis, the intensity is inadequate to support the prolonged existence of ball lightning. It is possible that the narrow-band radiation has a higher intensity in the direct vicinity of its point of origin, i.e., the ionized channel.

It would therefore be of particular interest to measure the radiation close to the lightning itself. Such measurements could be made by the stimulated lightning method developed by Newman.[9]

The effect that we have observed – discrete lines in the microwave spectrum of lightning – is of interest not only in the electromagnetic hypothesis of ball lightning but also from the point of view of plasma physics. It is desirable that it should be studied by other laboratories.

The authors thank P. L. Kapitsa for his continuous interest in this work and for his support, and L. A. Vainshtein and Yu. N. Khlopov for valuable discussions.

---

1) Because of the uncertainty in measuring the length of short pulses it is possible that the length here is determined by the fast scale and is therefore equal to 2 msec.

2) One pulse similar to that shown in Fig. 3 was recorded during the control measurements on October 12, 1972 but its frequency is identical with that of the radar station f_1.

General

Properties of underexpanded and overexpanded supersonic gas jets

A. V. Antsupov

(Submitted April 9, 1973)
Zh. Tekh. Fiz., 44, 372-379 (February 1974)

An experimental study is made of the conditions governing the regular reflection of a shock in underexpanded and overexpanded supersonic gas jets. Simple empirical equations are proposed for several structural properties of the flow of a single supersonic jet and of the jet emerging from a four-nozzle arrangement. The empirical behavior is used to develop a simple engineering method for calculating the jet structure.

Axisymmetric supersonic jets have an extremely wide variety of practical applications in various fields of modern technology. The recent intensification of interest in problems associated with the use of supersonic jets has stimulated several papers on jet flows and related questions (see, e.g., refs. 1-4). Despite the important progress which has been achieved, certain questions have received little study. There are serious difficulties involved in working out a method to calculate the properties over the entire flow field of a supersonic jet because the flow is generally three-dimensional, with regions of supersonic and subsonic velocities and shocks. The theoretical solutions available (found by the method of net points and characteristics) can be used in calculations for supersonic jets in the absence of subsonic internal regions;[5,6] when such subsonic internal regions exist the calculations can be carried out only in the initial gas-dynamic region (the first "barrel").[7,8] In practice, however, most jets have subsonic internal regions. Furthermore, since the viscosity is neglected, the range of validity of the numerical calculations based on the idealized model is not clear. The experiments which have been reported do not explain the structure of the jet in several ranges of the governing parameters which are of industrial interest. The flow immediately beyond the nozzle exit has been studied in detail, but several problems of practical interest require knowledge of the properties farther downstream along the jet. We report here an experimental study of the physical picture of the flow and of the properties describing the structure of the entire flow field of a single underexpanded or overexpanded supersonic jet and of a jet from a four-nozzle arrangement. The experiments were carried out with jets from nozzles having the properties shown in Table 1, for various ratios of the static pressure at the nozzle exit, p_a, to the pressure in the surrounding medium, p_s (i.e., for various values of index giving the deviation from the "nominal pressure conditions," $n = p_a/p_s$) from the value corresponding to separated flow in the nozzle to 15.

The Reynolds number, determined from properties at the nozzle exit and the diameter of the nozzle exit, d_a, is $(1-5) \cdot 10^6$.

Notation. p) Pressure; M) Mach number; $\varkappa$) polytropic index; n) index giving the deviation from "nominal pressure conditions;" θ) the vertex half-angle of the conical nozzle; i) number of nozzles in the arrangement. Subscripts: 0) Drag; a) exit cross section of the nozzle; s) surrounding medium; m) axis of the jet; bo) boundary of the jet; so) cross-section farthest downstream at which the sound velocity is reached at the jet axis. Linear dimensions are expressed in diameters of the nozzle exit and are written with an overhead bar. Here $\bar{p}'_0 = (p'_0 - p_s)/p_s$ is the relative overpressure. A prime denotes the value of a parameter behind the normal shock in the supersonic flow. The values of the parameters in the supersonic flow are determined from the indications of a Pitot tube and from shadow photographs of the supersonic jet. On the basis of the changes in the basic gas-dynamic parameters (the total and static pressures and the velocity), the flow field is arbitrarily divided into three regions in this study of the supersonic jet: the gas-dynamic, transition, and basic regions.[9] Figure 1 shows the flow scheme of the supersonic jet along with the basic geometric characteristics, from which we can determine the positions of the basic parts of the jet, construct its approximate contour, and determine the periodicity of the changes in the parameters in the gas-dynamic region. In this region, which begins at the nozzle exit, the gas-dynamic parameters vary over the transverse cross sections of the jet and vary periodically along the jet axis. The total pressure behind the normal shock at the minima increases with distance from the nozzle exit (Fig. 1). The maximum of the total-pressure (velocity) profile in the transverse cross section of the jet moves periodically along the radius with distance from the nozzle exit (from the periphery of the jet toward its axis and back). We can assume by convention that the gas-dynamic region is bounded by the cross

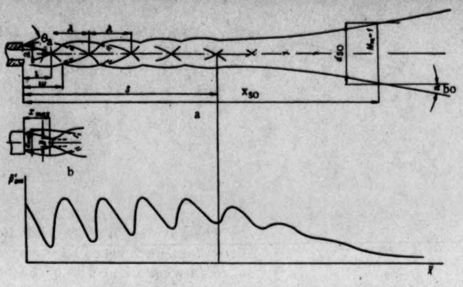

Fig. 1. Flow scheme of a single supersonic jet with regular (a) and irregular (b) reflection of the shock. Here D is the diameter of the central shock; d_{max} is the maximum diameter of the first "barrel" of the jet; S is the gas-dynamic region of the jet; x_{so} is the supersonic core of the jet.

section in which the pressure at a minimum of the jet axis, $\bar{p}_{0m}$, reaches a maximum (Fig. 1). The position of this cross section with respect to the end of the nozzle is given by the empirical equation

$$S = l + 4\lambda.$$

The periodic changes in the gas-dynamic parameters are caused by the shocks in this region. In the transition region the variations in the gas-dynamic parameters along the axis and radius become small; there is no clearly defined periodic structure, and the static pressure becomes equal to the atmospheric pressure, but supersonic flow is maintained in the central region. In the basic region the turbulent mixing of the jet and the surrounding medium reaches the axis; the velocity profile has a maximum at the jet axis and becomes approximately the same as that of self-similar flow. Three regimes of flow from the nozzle at supercritical pressure drops can be distinguished on the basis of the ratio p_a to p_s: the overexpanded regime ($n < 1$), the "nominal regime" ($n = 1$) and the underexpanded regime ($n > 1$). The qualitative differences between the jets corresponding to these three regimes are evident near the nozzle exit in the "initial gas-dynamic region," sometimes called the "first barrel." In this region the shocks develop fully. In all three regimes there can be a regular reflection of the incident shock (Fig. 1). In the case of irregular reflection, the incident shock is reflected from the axis, and a central shock (Mach disk) is formed; behind this disk the flow is subsonic, separated from the supersonic flow by a contact surface (Fig. 1b). In a jet emerging from a profiled nozzle with a uniform velocity field at the nozzle exit, there is a range of values of n near $n = 1$ in the "nominal" regime for all nozzles with $M_a \geq 1$ in which there is flow with regular reflection of an incident shock. In jets from conical nozzles the range n in which there is flow with regular reflection increases with increasing M_a and decreases with increasing vertex half-angle of the nozzle. Figure 2 shows our experimental results and those from refs. 1 and 10 on the range of n over which there can be regular reflection in an air jet (the internal region); here n is plotted as a function of the vertex half-angle of the nozzle θ_a and M_a. It follows from these results that for each value of M_a and for constant $\varkappa_a$ there is a limiting vertex half-angle θ_*, above which there is no regular reflection of the shock in the jet. On the basis of experimental results for an air jet from a conical nozzle, the following equation is proposed for the limiting vertex half-angle of the nozzle as a function of M_a:

$$\theta_* = \operatorname{arc\,tg}(0.22\sqrt{M_a - 1}).$$

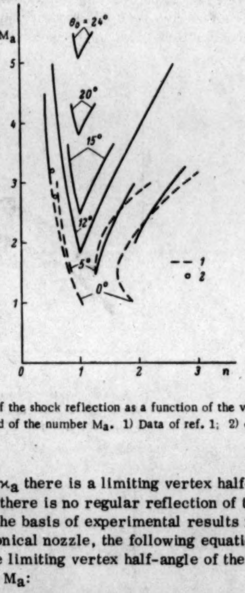

Fig. 2. Nature of the shock reflection as a function of the vertex half-angle of the nozzle and of the number M_a. 1) Data of ref. 1; 2) data of ref. 10 for $\theta_a = 0°$.

This functional dependence is shown in Fig. 3. In air jets from convergent nozzles ($M_a = 1$) with a subsonic region calculated from the Vitoshinskii equation, there is regular shock reflection up to $n = 1.94$.

The gas-dynamic region can be characterized by the following geometric parameters: l, the position of the point at which the incident shock is reflected; w, the length of the initial gas-dynamic region (the first barrel); λ, the wavelength of the periodic structure (the distance between

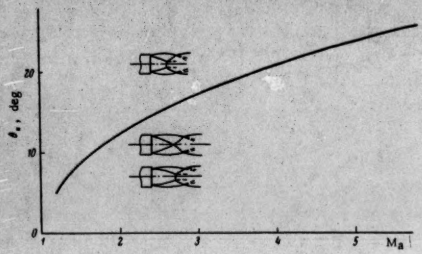

Fig. 3. Limiting vertex half-angle of the nozzle as a function of M_a for $\varkappa_a = 1.4$.

adjacent shock-reflection points); and the position and radius of the maximum cross section in the first barrel. The values of l, w, and λ for jets from conical nozzles with vertex half-angles $\theta_a < \theta_*$ and with $M_a \geq 1.5$ are essentially not functions of θ_a in the underexpanded regime and are self-similar in terms of the composite quantity $[\varkappa_a(M_a^2 - 1)]^{1/2}$. The quantities $\bar{l}/[\varkappa_a(M_a^2-1)]^{1/2}$ and $\bar{w}/[\varkappa_a(M_a^2-1)]^{1/2}$ are piecewise-linear functions of n in this underexpansion regime ($n \geq 1$):

$$\tilde{l} = \frac{\bar{l}}{\sqrt{\varkappa_a(M_a^2-1)}} = \frac{n}{1.20+0.30n},$$

$$\tilde{w} = \frac{\bar{w}}{\sqrt{\varkappa_a(M_a^2-1)}} = \frac{n}{0.80+0.25n}.$$

The wavelength of the periodic structure corresponds to the distance between adjacent maxima or minima of the curve showing the profile of the total pressure behind the normal shock, $\bar{p}'_{0m}$, along the jet axis (Fig. 1). The quantity $\bar{\lambda}/[\varkappa_a(M_a^2-1)]^{1/2}$ can be described by the following empirical equation as a function of n for regimes in which the periodic structure is observed:

$$\tilde{\lambda} = \frac{\bar{\lambda}}{\sqrt{\varkappa_a(M_a^2-1)}} = 1.05\sqrt{n} - 0.1.$$

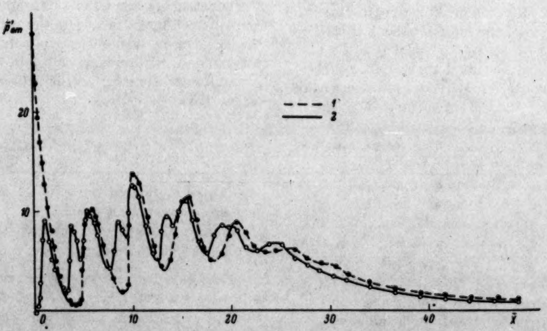

Fig. 5. Change in the relative total pressure behind the normal shock p'_{0m}, along the jet axis ($M_a = 2.65$, $n = 3$, $\varkappa_a = 1.4$). 1) Single jet; 2) composite jet.

The coefficients in the equations for the parameters l, w, and λ are determined by the method of least squares. Figure 4 shows the proposed functional dependences along with experimental data. This figure shows points corresponding to a hot-gas jet (alcohol–oxygen) with $\varkappa_a = 1.14$, found by Blagosklonov. In addition to studying a single supersonic jet, we studied the parameters of a composite air jet from a four-nozzle arrangement. Analysis of the photographs of the composite jet and of the pressure measurements by the Pitot tube along the axis of the composite jet shows that beyond the initial gas-dynamic region the composite jet has a repeating structure of shocks similar to the structure of a single jet of equivalent flow rate, having the same parameter values as the composite jet at the nozzle exit. The experimental values of l, w, and λ for the composite air jet from a four-nozzle arrangement are also shown in Fig. 4. In analyzing the experimental results we determine the diameter of the equivalent nozzle from

$$d_a^{\text{equ}} = \sqrt{i d_a}.$$

Comparison of the experimental results for single and composite jets shows that the values of l, w, and λ of the composite jet are described by equations which hold for the single jet which is equivalent in terms of flow rate.

Figure 5 compares the profiles of the relative total overpressure behind a normal shock along the axis of a single jet and along that of the equivalent composite jet. It follows from Fig. 5 that the pressure varies periodically along the axis of the composite jet over a distance of λ. There are surges in the pressure $\bar{p}'_{0m}$ for the composite jet not found in the single equivalent jet; these surges are also repeated at the same wavelength as that of the periodic structure. These surges result from the interaction of the additional shocks in the composite jet; in turn, the additional shocks result from the interference of the shocks of the composite jets in the initial gas-dynamic region. The structure of the initial gas-dynamic region of a composite jet is described in ref. 11. The basic maxima of the profile of the pressure $\bar{p}'_{0m}$ along the axis of the composite jet agree in magnitude and position with those in the equivalent single jet. The maximum pressures $\bar{p}'_{0m}$ at these additional peaks correspond to the positions of the minima of the pressure profile along the axis of the equivalent single jet. The numerical values of the minima of the $\bar{p}'_{0m}$ profile along the axis in a single jet are much smaller than those in the case of the composite jet, so that the amplitude of the variations in the pressure $\bar{p}'_{0m}$ at the axis of the single jet is higher than that in the composite jet. It follows from measurements of the pressure field in various meridional planes in the gas-dynamic region of the composite jet that the composite jet is cross-shaped in the gas-dynamic region in cross sections normal to the jet axis; correspondingly, there is an important difference between the profile of the gas-dynamic parameters in different planes.

In jets from nozzles with $\theta_a > \theta_*$, the values of the parameters l and w decrease with increasing θ_a, and the periodic wave structure is disrupted, so that the value of λ cannot be determined. This result is based on shadow and Töpler photographs of the jets and the measurements of the pressure by the Pitot tube along the jet axis. We propose the following empirical equations for l and w for $\theta_a > \theta_*$:

$$l = \frac{n}{1.20 + 0.30n}[1 - \operatorname{tg}(\theta_a - \theta_*)]\sqrt{\varkappa_a(M_a^2 - 1)},$$

$$\bar{w} = \frac{n}{0.80 + 0.25n}[1 - 1.2\operatorname{tg}(\theta_a - \theta_*)]\sqrt{\varkappa_a(M_a^2 - 1)}.$$

The diameter of the maximum cross section of the jet in the initial gas-dynamic region increases with increasing θ_a but is really not a function of M_a. We propose the following empirical equation for the diameter of the maximum cross section in a jet of cold air:

$$d_{\max} = (1 + 0.57\theta_a)n^{0.6}.$$

This functional dependence has been checked experimentally up to n = 40. As $\varkappa_a$ is reduced, the jet diameter increases.

The distance from the nozzle exit to a given maximum cross section of the jet is (0.8–1)l. In the case of irregular shock reflection there is an additional characteristic: the central shock. The diameter of the central shock is a strong function of the vertex half-angle of the nozzle and of n. Figure 6 shows the diameter of the central shock as a function of n for various values of the parameter θ_a. For jets from conical nozzles with θ_a = 12° in the underex-

Fig. 6. Diameter of the central shock as a function of n; the parameter is θ_a. M_a = 2, $\varkappa_a$ = 1.4, θ_a, deg: 1) 24; 2) 0; 3) 18; 4) 6; 5) 12.

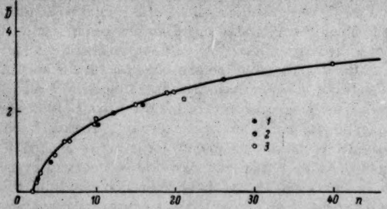

Fig. 7. Diameter of the central shock as a function of n for an air jet ($\varkappa_a$ = 1.4) from a convergent nozzle. 1) Experimental data of ref. 13; 2) of ref. 1; 3) M_a = 1. $\varkappa_a$ = 1.4, i = 1.

panded regime we propose the following empirical equation for the diameter of the central shock:

$$\bar{D}=\frac{0.65}{M_a}(n-0.55M_a)^{0.62}.$$

This equation is determined from studies of a cold air jet ($\varkappa_a$ = 1.4) in the range M_a = 1.5-5. Some of the results found by Blagosklonov for hot jets ($\varkappa_a$ = 1.14) agree with this equation. At $\theta_a \neq 12°$ the experimental results diverge from this empirical equation. For jets of cold air from a convergent nozzle the diameter of the central shock is described well by

$$\bar{D}=\lg n^{5/2}-\frac{3}{4}.$$

This functional dependence has been checked experimentally up to n = 40 and is shown along with the experimental data in Fig. 7.

The maximum diameter of succeeding barrels of the jet remains essentially constant over the gas-dynamic part of the jet. In the transition region the angle between the boundary and the axis increases, becoming constant in the basic region. From the experimental data we find the tangent of this angle in the basic region to be tan α_{bo} = 0.18, in agreement with the results of refs. 9 and 19. According to the experimental results, the angle between the boundary and the axis of the jet becomes constant at the end of the supersonic core of the jet, whose length is given by the empirical equation

$$\bar{X}_{so}=(4.4n+3+\beta)\exp 0.11\varkappa_a M_a^2.$$

This functional dependence holds up to n = 7. In jets with regular reflection, the value of the parameter β changes from 0 to 3 as a function of the shock intensities and the acoustic feedback.[12,14] When there is a central shock in the jet the value is β = 0. The diameter at the end of the supersonic core of the jet is found in terms of parameters at the nozzle exit on the basis of the equation expressing conservation of angular momentum along the jet:

$$\bar{d}_{so}=2.72\sqrt{nM_a^2+\frac{n-1}{\varkappa_a}}.$$

In the basic region of the composite jet the dimensionless velocity profiles agree with those of a single jet and can thus be described by the Schlichting "3/2 law."[12] The length of the supersonic core in the composite jet is essentially the same as that of the supersonic core in the equivalent single jet. Accordingly, calculations for the basic region of a composite jet can be carried out completely by the methods proposed for a single jet.

Gas-kinetic removal of neutral molecules from an ion beam

V. P. Ivanov

Scientific-Research Institute of Applied Mathematics and Cybernetics,
N. I. Lobachevskii Gor'kii State University

(Submitted February 17, 1973; resubmitted May 18, 1973)
Zh. Tekh. Fiz., 44, 380-386 (February 1974)

Impurity molecules are removed from ion beams by transverse gas flows produced by nozzles, capillary screens, etc. The high-velocity ions of the beam pass unhindered through the gas flow, but neutral molecules in the beam, moving at thermal velocities, collide with the molecules of the flow and are removed from the beam. It is difficult to carry out exact calculations for this complicated system. Below we propose an approximate method for calculating the required properties of the gas flow and evaluate the secondary contamination of the beam by the molecules from the gas flow.

1. INITIAL EQUATIONS

Impurity neutral molecules are removed from ion beams by transverse gas flows produced by nozzles, capillary screens, etc.[1] In real systems for gas-kinetic purification the density of the transverse gas flow is much higher than that of the neutral gas in the ion beam, so we can apparently neglect the influence of the beam on the flow and assume that the secondary contamination of the beam by the molecules of the gas flow is a consequence of the thermal motion of these molecules. Between the emitter and the absorber the transverse gas flow is randomized as a result of collisons between molecules of this flow. In the present paper we analyze the case in which the diameter of the ion beam is much larger than the mean free path of the molecules in the transverse flow and in which the gas in the flow is approximately in equilibrium.

A rigorous calculation of the gas flows between the emitter and the absorber requires the use of high-speed computers, even in the simplest case of one-dimensional flows.[2] Below, the randomized flow is analyzed approximately; it is regarded as the result of the relaxation of a spatially homogeneous gas from an initial state described by the velocity distribution function of the emitted molecules. The results of this analysis agree satisfactorily with the available exact data.[2] The contamination of the ion beam by molecules of the transverse flow is evaluated in terms of the number of molecules incident from a spatially homogeneous randomized flow on a specular reflection area at velocities lying within a specified solid angle around the normal to the area. This area is equal to the cross-sectional area of the ion beam and is parallel to the macroscopic velocity of the transverse gas flow.

The following simplified model for a real system for a gas-kinetic purification (a "gas gate") is the best approximation to these assumptions. We assume that the gas flows from an emitting strip I to a completely absorbing strip II of width ε between specularly reflecting side walls III, in which there are circular apertures S_1 and S_2 for the beam (Fig. 1). We assume these apertures to be small and to have a negligible effect on the state of the gas in the flow. To find the macroscopic velocity v and $\bar{\nu}$, the average thermal velocity of the molecules in the randomized flow from the probability-density distribution for the velocities of the molecules scattered by the emitter, we assume that the state of the randomized gas in the flow does not differ greatly from that immediately after randomization in an unbounded space, if the state of the spatially homogeneous gas is initially described by the velocity distribution function for the emitted molecules. In this case we can write

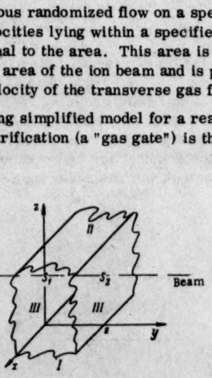

Fig. 1

$$v = \bar{\nu}_{0x}, \tag{1.1}$$

$$v^2 + \overline{\nu^2} = \overline{\nu_0^2}. \tag{1.2}$$

Here, ν_0 is the random velocity of a molecule scattered by the emitter. When the molecular velocities obey a Maxwellian distribution, the average thermal velocity of the molecules $\bar{\nu}$ is related to the mean square velocity $\overline{\nu^2}$ by

$$\overline{\nu^2} = 1.176\bar{\nu}^2. \tag{1.3}$$

The density of the gas flow n or the density of molecules in the flow N, which are related by

$$n = vN, \tag{1.4}$$

is chosen so that the density of molecules in the beam is reduced by a factor of α. If we assume that molecules are removed from the beam as a result of a single collision with molecules from the flow, and if we neglect the possibility that these molecules are returned to the beam as a result of subsequent collisions, we conclude that the probability for the molecules of the beam to traverse the gas flow is inversely proportional to the attenuation:

$$\exp\left(-\frac{\varepsilon}{\lambda}\right) = \frac{1}{\alpha}, \tag{1.5}$$

where λ is the mean free path of the beam molecules with respect to the molecules of the gas flow.

This mean free path is given by

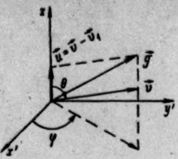

Fig. 2

$$\lambda = \int_0^\infty \frac{\nu_1}{\omega(\nu_1)} f(\nu_1)\, d\nu_1, \tag{1.6}$$

where ν_1 is the velocity of the beam molecule, $\omega(\nu_1)$ is the frequency at which beam molecules moving at ν_1 collide with molecules of the gas flow, $f(\nu_1)\,d\nu_1$ is the relative number of beam molecules having velocities in the interval $(\nu_1, \nu_1 + d\nu_1)$, and $f(\nu_1)$ is the probability-density distribution of the absolute velocities of the beam molecules.

The frequency at which a beam molecule moving at $\boldsymbol{\nu}_1$ collides with molecules of the flow moving at velocities $\mathbf{v} + \boldsymbol{\nu}$ is

$$d\omega = \pi (r + r_1)^2 |\mathbf{v} + \boldsymbol{\nu} - \boldsymbol{\nu}_1|\, dN = \sigma g dN. \tag{1.7}$$

Here, dN, the number of molecules of the gas flow with velocities between $\boldsymbol{\nu}$ and $\boldsymbol{\nu} + d\boldsymbol{\nu}$, is given by

$$dN = \frac{\beta^3 N}{\pi^{3/2}} \nu^2 e^{-\beta^2 \nu^2} \sin\theta\, d\theta\, d\varphi\, d\nu, \tag{1.8}$$

for an equilibrium gas, where $1/\beta = \bar{v}/1.128$, θ and φ are the polar and azimuthal angles giving the orientation of velocity $\boldsymbol{\nu}$ in the coordinate system x', y', z' moving with the gas (Fig. 2).

Using the notation $u = v - \nu_1$ and directing the z' axis along u, we can write

$$g = \sqrt{(u + \nu\cos\theta)^2 + \nu^2 \sin^2\theta} = \sqrt{u^2 + 2u\nu\cos\theta + \nu^2}. \tag{1.9}$$

Substituting Eqs. (1.9) and (1.8) into (1.7), integrating over φ, θ, ν, and treating the molecules in the thermal-velocity range as hard spheres with σ = const, we find

$$\omega = \frac{\sigma N}{\beta}\left[\frac{e^{-\beta^2 u^2}}{\sqrt{\pi}} + \operatorname{erf}(\beta u)\left(\beta u + \frac{1}{2\beta u}\right)\right], \tag{1.10}$$

$$\beta = \frac{2}{\sqrt{\pi}\,\bar{v}}, \quad \operatorname{erf}(x) = \frac{2}{\sqrt{\pi}} \int_0^x e^{-t^2} dt.$$

Since $\nu_1 \perp v$ and $u = |v - \nu_1|$, we have $u = (v^2 + \nu_1^2)^{1/2}$ (Fig. 3). Finally

$$\omega(\nu_1) = \frac{\sigma N}{\beta}\left[\frac{e^{-\beta^2 (v^2 + \nu_1^2)}}{\sqrt{\pi}} + \operatorname{erf}\left(\beta\sqrt{v^2 + \nu_1^2}\right)\left(\beta\sqrt{v^2 + \nu_1^2} + \frac{1}{2\beta\sqrt{v^2 + \nu_1^2}}\right)\right]. \tag{1.11}$$

As mentioned above, the transverse gas flow which removes neutral molecules from the beam is a source of secondary contamination of the beam. According to our assumptions, any molecule of the gas flow which intersects cross-section S_2 (Fig. 1) within a specified solid angle $\Delta\Omega$ around the normal to S_2 enters the beam.[1)] The flux density of molecules converted from the flow to the beam per unit time is

$$n_1 = n' p. \tag{1.12}$$

Here n', the number of molecules of the flow intersecting unit cross section S_2 in the equilibrium gas, is

$$n' = \frac{\bar{v} N}{4}, \tag{1.13}$$

and p, the probability that the velocity of a molecule intersecting cross section S_2 lies within solid angle $\Delta\Omega$, is, according to Eq. (2.5) of ref. 3,

$$p = \frac{\Delta\Omega \exp(-1.27 v^2/\bar{v}^2)}{\pi}. \tag{1.14}$$

It follows from these equations that as the thickness of the transverse gas flow is increased but the total gas flow rate is held constant there is a reduction of the secondary contamination of the ion beam by molecules of the gas flow without any change in the filtering properties of the flow.

We see from Eq. (1.5) that $\varepsilon/\lambda = \ln\alpha$, i.e., the mean free path of the beam molecules with respect to molecules of the gas flow, λ, is proportional to the thickness of the flow, ε ($\lambda \sim \varepsilon$). From Eq. (1.11), we find λN = const. Substituting $N \sim 1/\lambda \sim 1/\varepsilon$ into Eqs. (1.13) and (1.12), we see that the number of molecules of the gas flow which enter the beam, n_1, is inversely proportional to the beam thickness ε ($n_1 \sim 1/\varepsilon$). The total gas flow rate in the flow is proportional to εn; substituting in $n \sim N \sim 1/\varepsilon$, ~~we see~~ that the total flow rate is not a function of ε.

2. CALCULATED RESULTS

We calculate the density of a transverse argon flow 20 cm thick at which the flux density of neutral hydrogen in the ion beam, 20 cm in diameter, falls off by a factor of α = 400, from an initial value of $5.74 \cdot 10^{16}$ cm^{-2} · sec^{-1} to $1.43 \cdot 10^{14}$ cm^{-2} · sec^{-1}. We evaluate the secondary contamination of the beam by argon molecules under the condition $\Delta\Omega = 0.34 \cdot 10^{-2}$ sr (argon molecules which intersect cross section S_2 and enter circle S_3, 25 cm in diameter and 380 cm from S_2, enter the beam; Fig. 1). To be definite we assume that the argon molecules move away from the emitter surface and that the hydrogen molecules move along the beam with velocities obeying a Maxwellian dis-

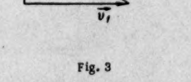

Fig. 3

tribution, with an average velocity corresponding to room temperature:

$$f(v_1)\,dv_1 = \frac{4\beta_1^3}{\sqrt{\pi}} v_1^2 \exp(-\beta_1^2 v_1^2) \qquad (2.1)$$

$$\beta_1 = \frac{1.128}{\bar{v}_1},$$

where $\bar{\nu}_1 = 17.7 \cdot 10^4$ cm/sec, $r_1 = 1.35 \cdot 10^{-8}$ cm, $\bar{\nu}_0 = 3.8 \cdot 10^4$ cm/sec, and $r = 1.7 \cdot 10^{-8}$ cm. The initial density of hydrogen in the beam $N_1 = n_1/\bar{\nu}_1 = 3.24 \cdot 10^{11}$ cm^{-3}; under equilibrium conditions a pressure of 10^{-5} torr corresponds to this density.

We analyze the operation of the gas gate for the following cases of the emission of argon molecules:

1) Emission in a cosinusoidal distribution.

2) Emission by means of a screen consisting of relatively short circular capillaries having a diameter-to-length ratio of $d/l = 0.115$.

3) Emission by means of a screen consisting of long capillaries with $d/l = 0.02$.

4) Normal emission, for which the velocities of the emitted molecules are parallel and normal to the emitter surface.

For the required degree of purification, the transverse flux of argon must be such that the mean free path of the hydrogen molecules among the argon molecules is, in correspondence with Eq. (1.5),

$$\lambda = \frac{\varepsilon}{\ln a} = 3.33 \text{ cm}. \qquad (2.2)$$

1. In the case of emission in a cosinusoidal distribution, the molecules have a Maxwellian distribution in the velocity half-space $\nu_{0z} > 0$, so we find $\nu_{0z}/\bar{\nu}_0 = 0.5$.

According to equations (1.1)-(1.3) the velocities of the ordered and thermal motion of the molecules of the flow are

$$v = 0.5\bar{v}_0 = 1.9 \cdot 10^4 \text{ cm/sec},$$

$$\bar{v} = 0.89\bar{v}_0 = 3.4 \cdot 10^4 \text{ cm/sec}, \; \frac{v}{\bar{v}} = 0.56. \qquad (2.3)$$

These values agree satisfactorily with those calculated on a BÉSM-6 computer for a one-dimensional gas flow. Those calculations show that in the case of a cosinusoidal emission distribution and with Kn = 0.125 the gas halfway between the planes is described approximately by a Maxwell distribution with $v = 0.3\bar{\nu}_0$, $v/\bar{\nu} = 0.52$ (ref. 2).

Using v, $\bar{\nu} \ll \bar{\nu}_1$, we find from Eqs. (1.6) and (1.11) that[2)]

$$\lambda N \approx \frac{1}{\pi(r + r_1)^2} = \frac{1}{\sigma} = 3.43 \cdot 10^{14} \text{ cm}^{-2}. \qquad (2.4)$$

Substituting the value of λ (2.2) into (2.4), we find the desired argon density in the transverse flow to be

$$N = 1.03 \cdot 10^{14} \text{ cm}^{-3}.$$

At equilibrium at room temperature this density would correspond to a pressure of $2.9 \cdot 10^{-3}$ torr. The flux density of the argon is, according to Eq. (1.4),

$$n = vN = 1.96 \cdot 10^{18} \text{ cm}^{-2} \cdot \text{sec}^{-1}.$$

According to Eqs. (1.12)-(1.14) the flux density of the argon in the ion beam beyond the gas gate is

$$n_1 = 6.3 \cdot 10^{14} \text{ cm}^{-2} \cdot \text{sec}^{-1}.$$

2. For the case in which the emitter is a capillary screen consisting of relatively short capillaries, we can use the directional pattern (shown in Fig. 2 of ref. 4) of the free-molecular flow of gas out of a tube with $d/l = 0.115$ and a numerical integration to find $\bar{\nu}_{0z}/\bar{\nu}_0 = 0.62$. Repeating the calculations above, we find the velocity of the ordered motion of the argon flow and the mean thermal velocity of the molecules in this flow after the randomization of the flow to be, respectively,

$$v = 0.62\bar{v}_0 = 2.35 \cdot 10^4 \text{ cm/sec}, \bar{v} = 0.82\bar{v}_0 = 3.12 \cdot 10^4 \text{ cm/sec}.$$

The density of the argon flow from the surface of the capillary screen is

$$n = 2.4 \cdot 10^{18} \text{ cm}^{-2} \cdot \text{sec}^{-1}.$$

The density of the argon flow in the ion beam beyond the capillary screen is

$$n_1 = 4.2 \cdot 10^{14} \text{ cm}^{-2} \cdot \text{sec}^{-1}.$$

To determine the dimensions of the capillaries which provide free-molecular gas flow, we assume that the gas is approximately in equilibrium in the volume from which the gas flows through the screen. If we neglect the oppositely directed flow of gas which is incident on the capillaries from the region between the emitter and the absorber, we can determine the gas density in the volume from

$$N_2 = \frac{4n}{kp_1\bar{v}_0}, \qquad (2.5)$$

where $\bar{\nu}_0$ is the mean thermal velocity of the gas molecules in the volume, k is the transmission of the screen, p_1 is the probability for transit of the gas molecules through the capillaries, and n is the density of the transverse gas flow. For capillaries having $d/l = 0.115$, we would have $p_1 = 0.128$ (ref. 5). Assuming k = 0.5, we find $N_2 = 4.0 \cdot 10^{15}$ cm^{-3}. The corresponding pressure is $1.1 \cdot 10^{-1}$ torr, and the mean free path of the gas molecules is about 0.5 mm. If the capillaries are shorter than 0.25 mm (and have diameters smaller than 0.029 mm), we conclude that the gas flow through the capillaries is approximately free-molecular flow.

3. We now assume the screen to consist of long capillaries, with $d/l = 0.02$. From the directional pattern in Fig. 2 of ref. 4, we estimate $\bar{\nu}_{0z}/\bar{\nu}_0 = 0.72$. Now the desired reduction of the amount of neutral hydrogen in the beam is achieved at an argon flux density of

$$n = 2.8 \cdot 10^{18}\ \mathrm{cm}^{-2} \cdot \mathrm{sec}^{-1}.$$

The flux density of argon in the beam beyond the gas gate is

$$n_1 = 2.4 \cdot 10^{14}\ \mathrm{cm}^{-2} \cdot \mathrm{sec}^{-1}.$$

The probability for transit of molecules through a tube with $d/l = 0.02$ is $p_1 = 0.0258$ (ref. 5). According to Eq. (2.5), the density of argon in the volume from which the argon flows through the screen must be

$$N_2 = 2.3 \cdot 10^{16}\ \mathrm{cm}^{-3}.$$

The corresponding pressure is $7 \cdot 10^{-1}$ torr, and the mean free path of the argon molecules is 0.085 mm. Accordingly, for approximately free-molecular flow of argon through the capillaries, the length and diameter of the capillaries must satisfy the conditions $l < 0.042$, $d < 0.00084$ mm.

4. We turn now to the case of normal emission. In this case the ordered and mean thermal velocities in the randomized argon flow are, respectively,

$$v = \bar{v}_0 = 3.8 \cdot 10^4\ \mathrm{cm/sec},$$
$$\bar{v} = 0.39\bar{v}_0 = 1.5 \cdot 10^4\ \mathrm{cm/sec}.$$

The argon flux density is

$$n = 3.9 \cdot 10^{18}\ \mathrm{cm}^{-2} \cdot \mathrm{sec}^{-1}.$$

The argon flux density in the beam is

$$n_1 = 0.8 \cdot 10^{12}\ \mathrm{cm}^{-2} \cdot \mathrm{sec}^{-1}.$$

Accordingly, when a capillary screen is used the contamination of the ion beam by argon molecules is slightly less than in the least favorable case of emission in a cosinusoidal distribution. For example, when a screen consisting of relatively short capillaries, with $d/l = 0.115$, is used, the contamination is reduced by a factor of 1.5, and when long capillaries ($d/l = 0.02$) are used, the contamination is reduced by a factor of 2.6. The directionality of the emission is highest in the case of free-molecular gas flow through capillaries; here relatively long capillaries must be very fine ($d \approx 0.0008$ mm for $d/l = 0.002$).

In the hypothetical case of normal emission the contamination of the beam by argon is reduced by a factor of more than 10^{-3}.

Let us check the original assumptions we have used in the calculation for a case of practical interest, that of a screen consisting of relatively short capillaries. The energy of the thermal motion of all the argon molecules in a unit volume is $m\bar{v}^2N/2 = 3.9\ \mathrm{ergs/cm^3}$, and the kinetic energy of the hydrogen molecules in a unit volume of the beam is

$$\frac{m_1\overline{v_1^2}N_1}{2} = 2.0 \cdot 10^{-3}\ \mathrm{erg/cm^3}.$$

Since the thermal energy of all the argon molecules in the beam–flow interaction region is much higher than the total kinetic energy of the hydrogen molecules in the same region, we can apparently neglect the perturbing influence of the beam on the flow. The mean free path of the argon molecules in the flow is about 1.9 cm (at equilibrium). The transverse dimension of the beam is much larger than the mean free path of the molecules in the gas flow, so we would expect a significant randomization of the argon in a large part of the interaction region.

In the case of a screen consisting of capillaries with $d/l = 0.115$ and $d < 0.03$ mm, a reduction of the number of neutral hydrogen molecules in the ion beam by a factor of 400 requires an argon pressure of $1.1 \cdot 10^{-1}$ torr in the volume from which the argon enters the screen. In this case the ion beam is contaminated with argon, whose flux density in the beam is $4.2 \cdot 10^{14}\ \mathrm{cm}^{-2} \cdot \mathrm{sec}^{-1}$ higher than the residual flux density of hydrogen in the beam, which is $1.4 \cdot 10^{14}\ \mathrm{cm}^{-2} \cdot \mathrm{sec}^{-1}$ (by assumption, the initial hydrogen pressure in the beam was 10^{-5} torr).

In conclusion the author thanks I. N. Golovin for suggesting the problem and for useful discussions.

---

1)Because of collisions, some of these molecules return to the flow, and the actual contamination of the beam is generally smaller than that found from this estimate.

2)This equation holds for any of the emission cases considered here.

Electron-microscope and x-ray study of thermionic emitters made from Mo–Pt alloys

B. B. Shishkin and R. S. Bakhtiyarov

M. V. Lomonosov Moscow State University

(Submitted November 9, 1972; resubmitted February 13, 1973)
Zh. Tekh. Fiz., 44, 387-399 (February 1974)

Emitters of alloys of Mo with Pt (having 1, 5, 10, and 15 wt.% Pt) have been studied in an emission electron microscope, a scanning electron microscope, and an x-ray microanalyzer. The formation of a film of the low-melting component (Pt) on the surface of the alloy with 1% Pt was studied in the emission electron microscope. As this film forms the local work function displays hysteresis in its functional dependence on the temperature. The Pt emerges onto the surface of the alloy along grain boundaries and at structural defects. The studies with the scanning electron microscope and the x-ray microanalyzer show that the Pt films are not monolayers. Histograms showing the distribution of the surface area of the alloy with respect to work function have been constructed on the basis of the electron emission microscopy. Current hypotheses regarding the mechanism for the emission of these alloys are discussed. An equation is derived for the thermionic current from an emitting surface for which the work function is inhomogeneous. An equation is derived for the thermionic-emission current of a metal whose conduction band has a complicated structure. Within the framework of the Sommerfeld model of the metal this equation is the same as the ordinary Richardson–Dushman equation.

INTRODUCTION

The search for thermionic emitters with specified properties has stimulated much work on binary and ternary alloys. Over the 10-year history of the study of alloys as thermionic emitters various hypotheses have guided the search for suitable emitters: the film hypothesis of Dyubua,[1–4] the spot-field hypothesis of Matskevich,[5] and Samsonov's hypothesis[6] of the relation of the thermionic emission of an alloy with its electronic energy spectrum.

The basic experimental results on the emission of binary and ternary alloys have been reviewed by Matskevich.[5] Among the papers published since this review, note should be taken of those dealing with experiments on the emission of various faces of alloy single crystals.[7–9]

The first two hypotheses can be tested by a joint electron-microscope and x-ray study (Sec. 1) of thermionic emitters.[10] In the present experiments, described below, the alloys are studied in an emission electron microscope, a scanning electron microscope, and an x-ray microanalyzer. The complexities involved in an analysis of the third hypothesis are discussed in Sec. 3 and in the conclusion.

1. EXPERIMENTAL RESULTS

The Mo–Pt alloy specimens are prepared in an MIFI-9 arc furnace on a water-cooled copper hearth in purified argon. The ingots are first cut into disks 7 mm in diameter and then ground and electropolished. We prepared and studied four alloys: alloy A, Mo + 1 wt.% Pt; alloy B, Mo + 5 wt.% Pt; alloy C, Mo + 10 wt.% Pt; and alloy D, Mo + 15 wt.% Pt.

Study of the alloys in the emission electron microscope. These experiments are carried out in a small, high-vacuum emission electron microscope with a magnetic immersion objective which we have designed and constructed. The apparatus is described in detail elsewhere.[11–13] Four specimens of alloys A-D and specimens of polycrystalline W and Mo are mounted simultaneously on the frame of the specimen holder. A Pt grid of known dimensions is mounted on one of the specimens for determination of the image magnification. The W and Mo specimens are used as test specimens for measuring the work function φ and its functional dependence on the temperature, $\varphi(T)$.

The pressure in the microscope is less than 10^{-7} torr in the experiments; the range of image magnifications is from ×50 to ×350. The collector system can be used to measure local emission currents with a resolution of 1.4 μ. In several of the experiments a chart recorder is connected to the output of a U-1-6 amplifying electrometer to record the contrast distribution curves.

The specimen temperature is determined by a pyrometer. In experiments carried out to find the temperature coefficient of the work function, we have constructed a calibration of the specimen temperature against the heating power. The temperature is determined with a tungsten/tungsten–rhenium thermocouple.

Typical emission photomicrographs of the alloys are shown in Fig. 1. Larger grains or "crystallites" are visible on the surfaces of alloys having relatively little platinum (A and B). On the surfaces of the grains themselves we see dark spots: platinum-enriched regions and interaxial regions of dendrites formed during the crystallization.

The images of alloy D (Fig. 1b) are radically different. The photomicrographs of this alloy reveal a clearly defined dendrite structure. The images in the emission micrographs of alloy C display a structure similar to that of alloy D.

To measure the effective local work function of the large grains (like those found on alloy A) it is sufficient to measure the emission current, the specimen temperature, and the magnification.[14] The current density at the specimen is

$$j(x, y)=\frac{I(xM, yM)}{S_0}M^2, \tag{1}$$

where I(xM, yM) is the current in the plane of the screen, M is the magnification, and S_0 is the area of the aperture in the screen.

We treat the complex emission patterns of type D, displaying the fine structure of the emission centers, in the following manner. First, we do not scan the electron beam[14] to obtain continuous contrast curves; instead we measure the local current at N points in the image plane. The current density calculated from Eq. (1) is substituted into the equation

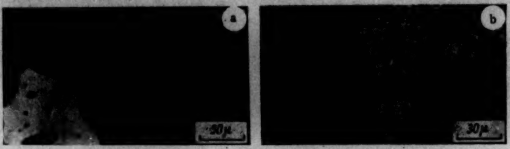

Fig. 1. Typical photomicrographs in the emission electron microscope. a) Alloy B; alloy D.

$$j_{(x,y)} = A'T^2 e^{-\frac{\overline{e\varphi}(x,y)}{kT}}. \tag{2}$$

In contrast with the Richardson–Dushman equation, here $\overline{e\varphi}(x, y)$ is the average of the work function over the region S_0/M^2 and $A' = A_0(1-R)\, f[\bar{\varphi}_\Sigma(x, y)]$, where $f[\bar{\varphi}_\Sigma(x, y)]$ is a functional of the generalized spot field.[14] If we set $A' = 120.4$ A/(cm^2 · deg^2), we can easily find $\overline{\varphi(x, y)}$ from the values of j(x, y) and M measured in the emission microscope. We call the work function calculated in this manner the "effective local work function," $\bar{\varphi}(x, y) = \varphi_{\text{loc}}$. To determine the emissivity of the entire emitter we carry out N measurements of φ_{loc}. The entire "spectrum" of work functions can be represented in the following manner. First, we find the maximum emission contrast $R = \varphi_{\max} - \varphi_{\min}$. Then we choose a method for partitioning the interval R into subintervals Δ. If the N measurement points are chosen at random, according to ref. 15, the interval R should be partitioned into subintervals

$$\Delta(\varphi) = \frac{R}{1 + 3.3 \log N}. \tag{3}$$

Accordingly, the magnitude of the subinterval $\Delta(\varphi)$ is a function of the number of measurements N, and for large values of N the subinterval $\Delta(\varphi)$ can be made arbitrarily small. Knowing $\Delta(\varphi)$, we can partition interval R into subintervals

$$m = \frac{R}{\Delta(\varphi)}. \tag{4}$$

In turn, the total number of measurements N is partitioned into subgroups N_i such that

$$\sum_{i=1}^{m} N_i = N. \tag{5}$$

Knowing R, N, and N_i we can construct a histogram of the density function of φ_{loc} over the surface of the cathode under study:

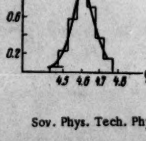

Fig. 2. Histogram of the density of the work function over the surface of a cathode of alloy D.

$$\mu(\varphi) = \frac{1}{N} \frac{N_i}{\Delta(\varphi)}. \tag{6}$$

When N is chosen satisfactorily$^{1)}$ we can assume that $N_i \sim dS$, and that $N \sim S$, the surface area of the cathode. Physically, the meaning of the function $\mu(\varphi)$ is the same as that of the function

$$\beta(\varphi) = \frac{1}{S} \frac{dS}{d\varphi}, \tag{7}$$

introduced in the analysis by Bulyginskii and Dobretsov.[17] Figure 2 shows a typical histogram of the density function of φ_{loc} for alloy D. This curve can be approximated by a Gaussian function over the interval ($\varphi_{\min} = 4.45$ V, $\varphi_{\max} = 4.75$ V):

$$\beta(\varphi) = 5.8 \exp[-96(\varphi - 4.62)^2]. \tag{8}$$

A knowledge of the function $\beta(\varphi)$ is frequently a sufficient basis for calculating the relations between the local emission parameters of a cathode and the integral parameters.[18]

Figure 3 shows the measured local work functions of the specimens studied over a broad temperature range; it is important to note that all the specimens are studied under identical vacuum conditions.

For tungsten and molybdenum we obtain values of the temperature coefficient of the work function which are slightly too high because of the relatively poor vacuum (10^{-7} torr).

For Mo–Pt emitters the temperature coefficient of the work function is higher. For alloy B $d\varphi/dT \sim 9 \cdot 10^{-4}$ V/deg, for alloy C, $6 \cdot 10^{-4}$ V/deg, and for alloy D, $1 \cdot 10^{-3}$ V/deg.

It should be noted that there are serious difficulties involved in measuring the local emission as a function of

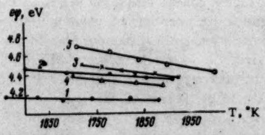

Fig. 3. The work φ_{loc} as a function of the temperature. 1) Mo; 2) W; 3) alloy B; 4) alloy C; 5) alloy D. These results correspond to the situation after the first heating at T > 2100°K.

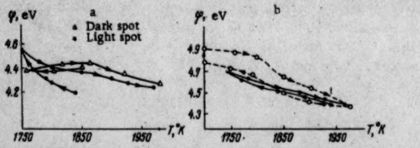

Fig. 4. The work function φ_{loc} as a function of the temperature for alloy A. a: Functional dependences obtained after 10 min. Filled points – grain with a low work function; triangles – high work function. b: Functional dependences for a grain with a high work function. Filled points – functional dependence obtained after 10 min; circles – after 40 min.

the temperature or time for a small cathode, because of the possible displacement of the image with respect to the collector system. We therefore carry out a more detailed study of alloy A, which has large regions of homogeneous emission. Figure 4 shows the work functions measured for two grains after alloy A is heated briefly at T > 2100°K (Fig. 4a).

The arrows show the direction in which the temperature is changed. A curve is recorded over an average of 10 min. For a grain with a low work function (curve 1), the work function increases sharply from 4.2 to 4.55 V as the temperature is reduced from 1840 to 1750°K. Interestingly, when the temperature is raised to its original value, the work function turns out to be 0.2 V higher. A further increase in the temperature reduces the work function. These drops in the emission with temperature changes are not observed for a grain with a high work function (curve 2).

We then record analogous curves for a single grain, varying the time (Fig. 4b). Curve 3 is recorded over 10 min; the overall behavior is the same as that of curve 2. Curve 4 is recorded over 40 min; over this time we again observe the "hysteresis forms" in the functional dependence of the work function on the temperature.

This type of change in φ_{loc} involving hysteresis is typical of film systems. In a subsequent series of experiments with alloy A we attempt to find suitable temperatures and times for visualizing migrational surface processes.

Figure 5 shows thermionic-emission photomicrographs characterizing one such process. Figure 5a shows the emitter surface immediately after the high-temperature heating. Let us consider the entire process for the case of a poorly emitting grain (which appears dark on the image), extended in the vertical direction (arrow 1). The entire area at the left emits homogeneously, except for grain boundaries and other structural defects.

Figure 5b shows the same region at a lower temperature. At the left of the reference grain we clearly see a grain which is essentially indistinguishable in Fig. 5a (where only the boundaries of this grain are visible). The arrows on the image show the positions at which the diffusing element is emerging. As expected, these positions correspond to grain boundaries and structural defects. The new grain, which becomes visible after the temperature is reduced, begins to emit less intensely than the first grain. We also observe contrast within the grain. In Fig. 5c this grain is covered by an optimum film, and the contrast within the grain disappears. In this last figure we see yet another grain, which emits like the reference grain. As the temperature is raised, the image in Fig. 5a can be restored, and the entire process can be repeated.

It is evident from these photomicrographs that the emission of alloy A is governed by the selective adsorption of individual faces, being a function of the relation between the rates of diffusion and desorption of the elements of the alloy. The conditions prevailing in the preliminary treatment of the specimen strongly affect the entire process. We believe that it is precisely because of this circumstance that migrational processes were not visible previously in alloys with small amounts of the low-melting component.

It is important to note that the adsorption and migrational processes of the low-melting component continue quite rapidly and, in the case of alloy A, are accompanied by the appearance of a hysteresis loop in the functional dependence of the local work function on the temperature for those grains on which these processes occur (Fig. 4).

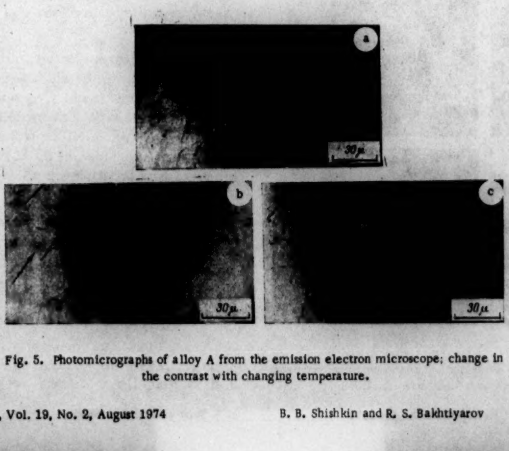

Fig. 5. Photomicrographs of alloy A from the emission electron microscope; change in the contrast with changing temperature.

Study of the alloys in the scanning electron microscope. These experiments are carried out in a JEOL apparatus.[2)] We are concerned primarily with alloy A.

To show that the image contrast in Fig. 5 changes because of adsorption and migration of the low-melting component (Pt) we exploit the circumstance that the secondary-electron-emission yield of platinum, σ_{Pt}, is higher than that of molybdenum, σ_{Mo} (ref. 19). We obtain images of the alloys in the scanning electron microscope after various types of heat treatment in the emission electron microscope.

The image contrast in the scanning electron microscope is produced by the microrelief and variations over the surface in the secondary-emission yield.[20] The images of alloys A-D obtained in the scanning microscope correlate well with the emission and optical photomicrographs. Figure 6 shows a series of photomicrographs of alloy A. The grain boundaries are bright, and the depressions on the surfaces of the grains turn out to be voids; only the edges of these voids are covered by a thin platinum film. The molybdenum base can be inspected within the voids at high magnification.

Study of the alloys in the x-ray microanalyzer. These experiments are carried out in a Cameca x-ray microanalyzer. We record the characteristic x radiation corresponding to the Lα line of platinum. We record curves showing the surface density of platinum after various types of heat treatment. Figure 7 shows the Pt distribution over the surfaces of alloys A and D after these alloys were held at T ≤ 1800°K. For alloy A the Pt content in the surface layer is much higher than that in the interior (Fig. 7a). A more complicated pattern is observed for alloy D (Fig. 7b). Here regions having the same platinum content as in the interior alternate with regions of a high platinum content (roughly twice that in the interior) on the surface.

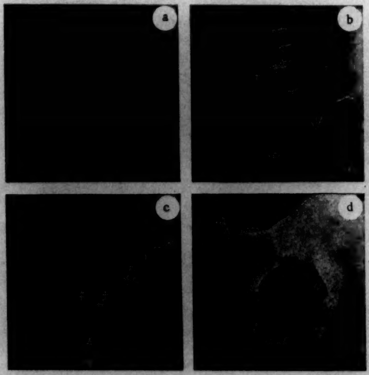

Fig. 6. Photomicrographs of the same region of alloy A obtained in the scanning electron microscope at various magnifications.

Intense evaporation of platinum begins at temperatures above 1900-2000°K. Figure 7b shows the platinum distribution for alloy B after it is held at T > 2000°K: The average Pt content falls to ~ 3%.

2. DYNAMICS OF THE EMISSION OF Mo–Pt ALLOYS

Here we compare our results with those hypotheses regarding the mechanism for the thermionic emission of alloys mentioned in the introduction.

Film hypothesis. The results described in Sec. 1 for alloy A, containing a small amount of platinum in molybdenum, confirm directly the role of a film mechanism in the thermionic emission of the alloy. It is important to emphasize that in a discussion of the results found in a study of only certain emission processes there is a possible ambiguity in the interpretation.

This ambiguity results from the interaction of the specimens with the residual gas in the emission electron microscope (we recall that the pressure in our apparatus was $p \sim 10^{-7}$ torr). Accordingly, in an attempt to distinguish the role of the specimen itself in its emission, we also carry out a multifaceted electron-microscope study of specimens of the alloys as well as test specimens of W and Mo. On the basis of the study of alloy A in the scanning microscope (Fig. 6) and in the x-ray microanalyzer (Fig. 7) we can assert that there are temperature ranges and heating times which result in the formation of a platinum film over the surface of alloy A.

Accordingly, the electron emission of alloy A is governed by both the emitter itself (i.e., by diffusion of platinum to the surface, migration of platinum, and desorption) and the interaction of the emitter with the residual gas in the apparatus. Each of these processes is a strong function of the temperature and is characterized by a certain heat of adsorption (or desorption) or diffusion (or migration) coefficient; together, they lead to a functional dependence of φ_{loc} on the temperature which displays hysteresis (Fig. 4). Separate study of these processes requires further refinement of the procedure for the experiments in the emission microscope: improving the vacuum in the apparatus, measuring the partial pressures of the residual gases, and carrying out various types of prototype experiments.

The experiments in the emission microscope show that platinum moves to the surface particularly rapidly along grain boundaries and at structural defects. As a result, each grain of the alloy is inhomogeneous with respect to emission. A more or less complicated distribution of φ_{loc} over the surface of the alloy is ultimately established after the heat treatment in the emission microscope (see, e.g., Fig. 2).

The fact that the Pt films can be observed in the scanning microscope and the x-ray microanalyzer as well as in the emission microscope shows that these films are not monolayers; on the contrary, they are rather thick. The appearance of these films on the surface of the alloy is accompanied by an increase in φ_{loc} (Fig. 4).

On the basis of our observation of surface processes in the emission microscope and measurement of the $\beta(\varphi)$ distributions (Figs. 1 and 2) we can also discuss the sec-

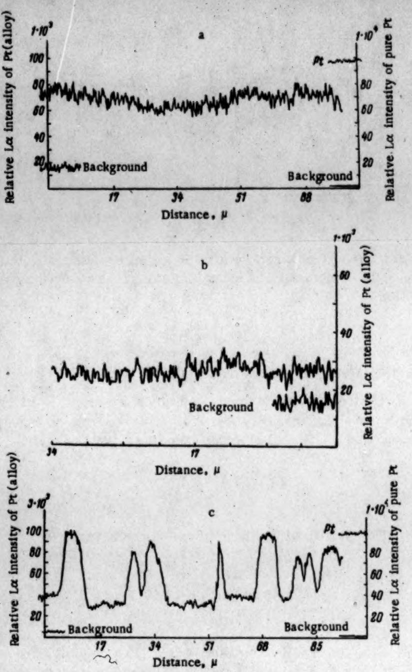

Fig. 7. Distribution of Pt over the surfaces of the alloys. a) Alloy A; b) alloy D; c) alloy B after heating.

ond hypothesis for the emission mechanism of binary alloys.

Hypothesis of spot fields. If the $\beta(\varphi)$ curves have been obtained, they can be used to relate the local emission of a specimen to the integrated emission.

We assume that there are m types of emission centers over the surface of a specimen. The total area occupied by centers of type i is assumed to be S_i. Then we have $\sum_{i=1} S_i = S$, where S is the total surface area of the emitter.

We assume that the values of $\varphi_{i\min}$ and $\varphi_{i\max}$ are known for each type of emission center. However, each type of center can be characterized by a function $\beta i(\varphi)$. If the emission centers emit independently, we can calculate the density of the emission current from spots of type i:

$$j_i = \int_{\varphi_{i\min}}^{\varphi_{i\max}} A_i T^2 \exp\left(-\frac{e\varphi}{kT}\right)\beta_i(\varphi)\,d\varphi. \tag{9}$$

We find the total current emitted by the entire surface to be

$$I = \sum_{i=1}^{m} S_i j_i. \tag{10}$$

Using Eq. (10) we can easily find (under the assumption of independently emitting spots) the work function of a spotty emitter averaged over the electron current:

$$\varphi^e = -\frac{kT}{e}\ln\frac{\sum_{i=1}^{m} S_i \int_{\varphi_{i\min}}^{\varphi_{i\max}} A_i \exp\left(-\frac{e\varphi}{kT}\right)\beta_i(\varphi)\,d\varphi}{AS}. \tag{11}$$

In deriving Eq. (11) we have formally divided the entire emitting surface into m types of spots. This division should of couse be carried out in correspondence with those physicochemical processes which occur on the surface of a complicated emitter. In other words, it is desirable to find criteria for sorting the spots. Such criteria can be based on physical processes which occur on the surface of a binary alloy. On the surface there are spots of the following types:

1. Various faces of the grains of the alloys components.

2. Various faces of the grains of various structural phases of the alloy.

3. Faces of grains covered by residual gas films, which give a set of values of φ_i which are functions of T, p (the pressure), and the residual gas composition.

4. Faces covered by films of material which have diffused from within the emitter; again the values of φ_i are functions of T.

5. Various types of chemical compounds which are essentially always present on the surface (particularly, carbides and oxides).

This list could of course be extended. In the experiments carried out in the emission microscope it is not always possible (particularly for complicated structures of type D) to specify (Fig. 1b) the type of spot corresponding to a given part of the surface. We therefore do not characterize a complicated cathode by a set of functions $\beta_i(\varphi)$ but by a single function $\beta(\varphi)$ (Fig. 2). In this case we can calculate $\tilde{\varphi}^e$ from an equation like (11):

$$\varphi^e = -\frac{kT}{e}\ln\frac{\int_{\varphi_{\min}}^{\varphi_{\max}} A_\varphi \exp\left(-\frac{e\varphi}{kT}\right)\beta(\varphi)\,d\varphi}{SA}. \tag{12}$$

Knowing $\beta(\varphi)$ and assuming $A_\varphi = A = \text{const}$ we can calculate any average work function of the emitter (i.e., an average over the surface, an average over the electron or ion current, an average photoelectronic work function, etc.).[11,18]

Equations (10) and (11) also contain possible nonmonotonic functional dependences of the thermionic-emission current of the binary alloy on the alloy composition.

Unfortunately, we have nothing to compare the calculations with, because we do not have results from a study of the integrated emission of specimens of Mo–Pt alloys.

We emphasize that Eq. (11) is derived under the assumption that the emission of the various spots is independent. The situation is much more complicated if the interaction of spots is taken into account. The extremely interesting effects which arise in this case are responsible for the fine structure of the anomalous Schottky effect. We propose to discuss these questions in a separate paper.

In concluding this section we support the assertion[21] that the experimental procedure must be carefully thought out (and described in detail in the corresponding papers!) in each specific study of the integrated work function of a complicated specimen, $\overline{\varphi}$.

3. POSSIBLE RELATION BETWEEN THE THERMIONIC EMISSION OF METALS AND ALLOYS AND THE COMPLICATED STRUCTURE OF THE CONDUCTION BANDS

The density distribution of electronic states in the conduction band, $\rho(\varepsilon)$, has now been calculated theoretically and determined experimentally for several metals and alloys. It is well known that knowledge of these functions yields information about the energy distribution of electrons in the conduction band,

$$f(\varepsilon)=\rho(\varepsilon)\frac{1}{\exp\left[\frac{\varepsilon-\varepsilon_F}{kT}\right]+1}, \tag{13}$$

where ε is the electron energy (measured from the bottom of the conduction band of the metal) and ε_F is the Fermi energy. If the function $f(\varepsilon)$ is known for a given metal or alloy, most of the characteristics of a metal governed by conduction electrons can be calculated automatically.[22,23]

An experimental method for determining $\rho(\varepsilon)$ over a broad energy range – the Spicer photoemission method[24] – has been used in experimental studies of Cu and Ag (ref. 25), W (ref. 26), Mo (ref. 27), Pt (ref. 28), and several other specimens. In particular, a peak has been found in $\rho(\varepsilon)$ immediately adjacent to the Fermi level in the conduction band of Mo (ref. 27) (Fig. 8). This peak is due to d electrons of molybdenum and naturally is manifest in experimental studies of any of the optical properties of this metal (the spectral coefficients, the quantum yield of photoelectrons, and their distribution functions).

The results of experiments on the thermo-photoemulsion of Mo and the Mo–BaO system carried out in our laboratory find a natural explanation in terms of this peak.[29] It is hoped that the thermionic-emission effects are related, to the complicated structure of the conduction bands of real metals and alloys. The Samsonov hypothesis[6] follows directly from this idea but ignores the fundamental difficulties involved here.[30]

In a formal discussion we can analyze the thermionic emission of a real material on the basis of this scheme. From the $\rho(\varepsilon)$ distribution found from quantum-mechanical calculations[31] at T = 0°K or found experimentally and from the Fermi function we can find,[3] according to (13), the distribution function $f(\varepsilon)$.

We assume that the work function of the specimen, φ, is known (from either theory or experiment). Then those

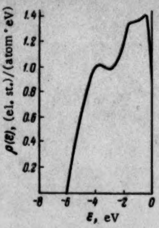

Fig. 8. Density of states in the conduction band of Mo, according to the experimental results of ref. 27.

electrons whose kinetic energies $\varepsilon_\perp$ (associated with the velocity component normal to the surface) satisfy the condition

$$\varepsilon_\perp \geqslant \varepsilon_F + e\varphi \tag{14}$$

participate in the thermionic emission.

The relative number of such electrons is given by the yield function $T(\varepsilon)$ (refs. 24, 29). If we assume an isotropic distribution of electron velocities, we can write

$$T(\varepsilon)=\left(\frac{1}{2}-\sqrt{\frac{\varepsilon_F+e\varphi}{\varepsilon}}\right). \tag{15}$$

The density of emitted thermionic electrons is

$$n=\int_0^\infty f(E)\,T(E)\,dE, \tag{16}$$

where the energy E is measured from the vacuum level. Finally, we find the thermionic-emission current density by the standard method:

$$j=en\bar{v}, \tag{17}$$

where $\bar{v}$ is the most probable velocity of the emitted electrons.

Using the expression for $\rho(\varepsilon)$ found on the basis of the Sommerfeld model of a metal,[22] we find

$$j=\frac{4\pi mek^2}{h^3}T^2\Psi\left[\frac{E}{kT},\ \frac{\varepsilon_F+e\varphi}{kT}\right]\exp\left(-\frac{e\varphi}{kT}\right)=A_0\Psi T^2\exp\left(-\frac{e\varphi}{kT}\right), \tag{18}$$

i.e., the ordinary Richardson–Dushman equation. The complicated functional Ψ in (18) is approximately equal to unity, but always slightly smaller.

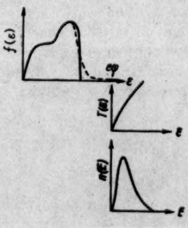

Fig. 9. Scheme for calculating the thermionic emission current of molybdenum.

The scheme for the numerical calculation of j for Mo on the basis of the actual $\rho(\varepsilon)$ distribution is clear from Fig. 9. Similar schemes can be easily worked out for Pt, W, and other metals, for which $\rho(\varepsilon)$ and φ are known.

Using the formal scheme described above for analyzing thermionic emission, we can also find the hysteresis forms of the functional dependence of the thermionic emission current on the temperature and thus find the effective values of φ_{loc} measured in our experiments (Figs. 3 and 4). Exact calculations cannot be carried out at present because the functions $\varepsilon_F(T)$ and $\varphi(T)$ are not known.

According to this scheme for analyzing the thermionic emission of metals and alloys having a conduction band complicated in structure, the thermionic-emission current density is given by

$$j = A[\rho]T^n \exp\left[-\frac{e\varphi}{kT}\right], \tag{19}$$

where A is governed by the density of electronic states in the conduction band of the emitter; the exponent n can be either larger or smaller than 2, depending on $\rho(\varepsilon)$ and $T(\varepsilon)$.

CONCLUSION

The results of this joint electron-microscope and x-ray study of emitters of Mo–Pt alloys cannot be explained on the basis of any single model for the emission of an alloy.

We have reported the first observation of the formation of films of the low-melting component (Pt) on the surface of a binary Mo–Pt alloy having a small amount of Pt (1%). Our experimental results show that these films, which lead to an increase in the value of φ_{loc}, are not monolayers. The frequent attempts which have been made to explain the results of a study of the integrated emission of alloys on the basis of the model of an electrical double layer (this model is convenient for explaining the "arrangement" of atoms on any ideal, usually single-crystal, surface) are not satisfactory for the case of Mo–Pt alloys. Furthermore, there is a basis for assuming that this double-layer model is also unsuitable for alloys of other compositions.

On the basis of this experimental study of the spottiness of emitters of these alloys, we can relate the local thermionic-emission properties to the integrated properties, which are usually measured in practice. On the basis of Eqs. (11) and (12) for $\bar{\varphi}^e$ derived here, it is clear that we can expect a complicated, nonmonotonic functional dependence of $\bar{\varphi}^e$ on the alloy composition [through $\beta_i(\varphi)$ and $\beta(\varphi)$]. The situation which arises in an attempt to relate the integrated and the local emission properties of an emitter is considerably more complicated when the fine structure of the anomalous Schottky effect is taken into account.[18]

We believe that many aspects of the phenomenon of thermionic emission (not only the emission of binary alloys) can be explained on the basis of the scheme analyzed above [(13)–(18)].

In this formal scheme (and we again emphasize that it is only a formal scheme) the thermionic emission current density is governed by, first, the state of the specimen surface [by the quantity $e\varphi$ which appears in the exponential function in $e\varphi$] and, second, the internal electronic structure of the specimen (the electronic-state density is related to the value of the constant A_0).

Our scheme for analyzing the phenomenon of thermionic emission is completely consistent with the current quantum-mechanical theory of this phenomenon.[32]

Our scheme for analyzing this phenomenon contradicts the classical thermodynamic description,[33] according to which A_0 is a universal constant for all thermionic emitters, governed by the zero of the entropy.

This contradiction, which is a fundamental question regarding the mechanism for this phenomenon, has already generated some discussion[6,30] but unfortunately has not yet been resolved.

---

1) The usual test of the suitability of the choice is the agreement of the histograms for N_1 and N_2 measurements, where $N_2 > N_1$ (ref. 16). In ref. 16, $\Delta(\varphi)$ is chosen to be the error in the measurement of φ_{loc}. It follows from our experiments that $\Delta(\varphi)$ must be chosen to be of the order of or at least no smaller than the error in the method used to measure φ. This error is governed by the operating stability of the apparatus (the constancy of M, the stability of the gun which heats the specimen, etc.) and is generally much smaller than the error in the measurement.

2) The authors thank R. S. Gvozdover for assistance in the experiments in the JEOL scanning electron microscope.

3) After multiplication of the functions appearing in (13), the resulting curve must be renormalized.

Analysis of the cathode spot in a vacuum arc

I. I. Beilis

Institute of High Temperatures,
Academy of Sciences of the USSR, Moscow

(Submitted August 4, 1972; resubmitted June 26, 1973)
Zh. Tekh. Fiz., 44, 400–410 (February 1974)

A complete system of equations is given for the cathode region of a vacuum arc. Long-lived cathode spots are considered. The effect of the total spot current on the degree of ionization, the cathode temperature, the electric field, the current density, the electron temperature, the charged-particle density, and the rate of removal of vapor from the cathode region is determined. The effects of the thermophysical and emission constants of the cathode material and changes in the cathode potential drop and the mass flow rate of material from the cathode are also found. The role of multiply charged ions and excited atoms in the ion current in the cathode region is also studied.

At the present time the literature does not contain a theory for the cathode spot of an arc discharge. Detailed analyses of existing attempts to explain the cathode processes in the electric arc have been given by Rakhovskii[1] and by Kesaev.[2] As a rule, such attempts are unsatisfactory in a number of ways. For example, the theoretical model contains a free parameter, with the result that the system of equations is not closed. Moreover, the theoretical models used by various authors are concerned with processes occurring in the solid and at its surface (heat conduction, emission of electrons from the cathode) whereas the processes taking place in the cathode region (motion of the charge carriers, rate of generation and loss, heating of the cathode gas) are usually ignored. The attempt of Kozlov and Khvesyuk[3] to fill this gap is unsuccessful since their results contradict the hypotheses on which their paper is based. In a recent paper, Kulyapin[4] concerns himself solely with the thermophysical and emission processes at the cathode without relating them to the parameters of the plasma.

A physical and mathematical model free from the above defects is developed in refs. 5 and 6 on the basis of an analysis of the elementary processes occurring in the cathode region of a vacuum arc. In the range of parameters considered in ref. 6 the cathode plasma, in which the electric field is relatively small ($E_{\text{plasma}} \leqslant 10^3$ V/cm), is separated from the cathode by a collisionless sheath, across which almost all the cathode potential drop occurs. Plasma ions are accelerated in this collisionless sheath and impinge upon the cathode, heating it through conversion of their kinetic and potential energy. The potential distribution and electric field in the collisionless sheath are determined by the positive space charge of ions arriving from the plasma. The electric field arising in this sheath facilitates emission of electrons from the cathode and communicates energy to charged particles moving in this sheath. Emitted electrons, which are accelerated by the positive space-charge field, carry energy to the cathode plasma. This energy is dissipated in the cathode plasma in ionization and heating of the plasma. Ionization occurs both through collisions with fast electrons and through thermal ionization. The resulting ions diffuse toward the cathode surface at a rate determined by resonance charge exchange.

In this model the parameters taken to be prescribed are: the total current at the spot I, the cathode voltage drop u_c, the mass rate of erosion of cathode material G_{er}, and the physical constants of the cathode material. The quantities subject to determination are: the current density i_0, the fraction of the current density carried by electrons $s = i_e/i_0$, the cathode temperature T_C, the heavy-particle temperature T, the electron temperature T_e, the degree of ionization α, the macroscopic rate of removal of electrode material from the cathode region u, the plasma density, and the electric field E at the cathode surface.

In this paper we present a detailed analysis of the solution of the system of equations of refs. 5 and 6 over a wide range of values of I, and we also determine how the parameters of the cathode spot vary with the thermophysical constants, the work function, the cathode voltage drop, and the amount of material eroded from the cathode. We also examine the steady-state regime of the discharge at the cathode.

THE SYSTEM OF EQUATIONS

For convenience we list the complete system of equations describing the processes in the cathode region of a vacuum arc.[5,6] The equation for the ion flux is

$$\left.\begin{aligned} \Gamma_i &= -(1+\theta) D_{ia}\frac{dn_i}{dx} + n_i u + \alpha D_{ia}\psi, \\ D_{ia} &= \frac{0.4 \cdot V_{iT}}{(n_a + n_i)\sigma_{ai}}, \quad \theta = \frac{T_e}{T}, \\ \psi &= \frac{1}{kT}\left[\frac{dP}{dx} - n_i\frac{d(kT_e)}{dx} - (n_a + n_i)\frac{d(kT)}{dx}\right], \quad \alpha = \frac{n_i}{n_a + n_i}. \end{aligned}\right\} \tag{1}$$

The ion equation of continuity is

$$\frac{d\Gamma_i}{dx} = \sigma_i n_a N_{e0} \exp\left[-\int_0^x (n_a\sigma_i + 2n_i\sigma_{\text{cr}})\,dx\right] + \beta n_0^2 n_i\left[1 - \left(\frac{n_i}{n_0}\right)^2\right]. \tag{2}$$

The boundary conditions are

$$D_{ia}\frac{dn_i}{dx}\Big|_{x=0} = \frac{1}{2} n_a v_{iT}; \quad n_i|_{x=\infty} = n_0; \quad n_a = P/kT - (1+\theta) n_i.$$

The energy balance equation for the plasma electrons is

$$\begin{aligned} s(eu_e + 2kT_{\text{C}}) - (1 - s + \alpha\zeta) u_i = 3kT_e(1 + \alpha\zeta) \\ + Q^{**} + (1 - s) kT_e\left(\frac{m_i T_e}{m_e T}\right)^{1/2} e^{-\frac{eu_e}{kT_e}}, \end{aligned} \tag{3}$$

where

$$Q^{**} = \frac{1}{i_0}\int_0^l \frac{3m_e}{m_i}\frac{n_i}{\tau_{ie}}(T_{\text{e}} - T)\,dx; \quad \zeta = \frac{e G_{\text{er}}}{m_i I}.$$

Equation (3) allows for heating of the plasma electrons by an energetic beam of electrons accelerated in the cathode drop region and for cooling through the process of ionization, through energy transfer to heavy particles in elastic collisions, and through the reverse flow of plasma electrons in the tail of the Maxwellian distribution with an energy in excess of eu_c.

The energy equation for the heavy component is

$$\frac{5}{2}k(n_a+n_i)u\frac{dT}{dx}=-\frac{d}{dx}\left(-\lambda_a\frac{dT}{dx}+\mu_{ai}J_i\right)+\frac{3m_e}{m_i}\frac{n_i}{\tau_{ie}}k(T_e-T),$$
$$\mu_{ai}=0.17n_akT/n_i,\ J_i=\Gamma_i-n_iu. \tag{4}$$

with boundary conditions: $T|_{x=0}=T_c$, $(\lambda_a dT/dx)_{x=\infty}=q_{iT}$.

Let us estimate the contribution of the term Q^{**} in (3). We integrate (4) to obtain

$$\frac{5}{2}k(T_e-T_c)u(n_i+n_a)=-(q^l_{i+a}-q^w_{i+a})+\int\limits_0^l\frac{3m_ek(T_e-T)n_i}{m_i\tau_{ie}}dx. \tag{5}$$

Taking the expression of Gogosov et al.[7] for the heat flux to the wall q^w_{i+a}, and assuming that the heat flux at the external boundary of the region of relaxation $q^l_{i+a}=0$, it is easy to show that $i_0Q^{**}=(5kT/2)(1+7T_c/5T_e)eu(n_i+n_a)$. The role of Q^{**} in Eq. (3) can be estimated, for example, in terms of its ratio to the first term on the right side of this equation. It is readily seen that if $(1+\alpha\xi)\cdot\theta/5eG_{er}>1$, then the term Q^{**}, which describes the energy transferred by the electrons to the heavy particles, can be neglected in Eq. (3). On the basis of this condition the term Q^{**} will not be taken into account in (3) in the specific calculations given below for the investigated range of variation of the current I.

Let us now consider the role of the terms in (4). For convenience, utilizing $(n_i+n_a)u=G_{er}i_0/Im_i$, we rewrite (4) in the following form:

$$\frac{d}{dx}\left(-\lambda_a\frac{dT}{dx}+\mu_{ai}J_i+\frac{5}{2}kT\frac{G_{er}i_0}{Im_i}\right)=\frac{3m_e}{m_i}\frac{n_i}{\tau_{ei}}k(T_e-T). \tag{6}$$

In determining the temperature T of the heavy particles from Eq. (6) all the terms of this equation must, generally speaking, be taken into account.

However, a detailed examination [by comparing the individual terms in (6)] of the region in which the electron and heavy-particle temperatures become equal has shown that the length of this region can be much greater than, much smaller than, or comparable with the relaxation region, depending on the charged-particle density. In the first and second cases, without solving Eq. (6) one can write T = const in the relaxation region; this constant is equal, respectively, to T_c or T_e. For example, for $n_i\sim 10^{18}$ cm^{-3} and with no density gradient ($J_i=0$), Eq. (6) acquires the form $d[-\lambda_a(dT/dx)]/dx=0$, from which it follows that $T=\text{const}=T_c$. When the relaxation region and the region in which the temperatures equalize are comparable, the heavy-particle temperature in the Debye sheath will not be a constant.

For the range of parameters investigated below it is not possible to make an unequivocal estimate of the heavy-particle temperature T. Accordingly, we shall solve our system of equations for $T=T_c$; however, to find the effect of a variation in the absolute value of T, the case $T=T_e$ is also considered.

Let us now consider the equations describing the processes taking place within the solid and at its surface.[1)]

The electron current i_e in the collisionless sheath adjacent the cathode is determined from the equation

$$si_0=\frac{4e\pi m_ekT_c}{h^3}\int\limits_{-\infty}^{\infty}\frac{\ln\left[1+\exp\left(-\frac{\varepsilon}{kT_c}\right)\right]d\varepsilon}{\exp\left[\frac{6.85\cdot 10^7(\varphi-\varepsilon)^{3/2}\theta(\tilde{y})}{E}\right]}-\frac{e}{4}n_iv_{eT}e^{-\frac{eu_c}{kT_e}}. \tag{7}$$

The first term on the right side of Eq. (7) determines the emission current allowing for the action of the positive space-charge field on the electrons; the electron energy distribution ε in the conduction band at the corresponding cathode temperature is described by Fermi–Dirac statistics. The second term on the right gives the number of electrons from the plasma with energies greater than eu_c.

In the calculations the following expression[8] is used for $\theta(\tilde{y})$:

$$\theta(\tilde{y})=1-\tilde{y}^2\left[1+0.85\sin\left(\frac{1-\tilde{y}}{2}\right)\right].$$

The system of equations is solved below for the so-called long-lived spots. The elementary processes taking place in such spots can be regarded as steady-state, while the unsteady burning of the discharge can be ascribed solely to the establishment of the thermal process in the bulk of the electrode. Accordingly, the lifetime of the cathode spot will vary from 10^{-4} to 1 sec. Energy balance at the cathode gives:

$$0.24\left[(1-s)u_{\text{eff}}i_0+\frac{e}{4}n_iv_{eT}e^{-eu_c/kT_e}(2kT_e+\varphi-3.62\cdot 10^{-4}\sqrt{E})\right]$$
$$=2\lambda_T\sqrt{\frac{i_0}{I}}(T_c-300)\left[\frac{2}{\pi}\operatorname{arc\,tg}\sqrt{\frac{4\pi a i_0 t}{I}}\right]^{-1}+\left(\lambda_e+\frac{2kT_c}{m_i}\right)G_{er}\frac{i_0}{I}$$
$$+1.4\cdot 10^{-12}T_c^4, \tag{8}$$
$$(1-s)u_{\text{eff}}=(1-s)(u_c+u_i)-\varphi+3.62\cdot 10^{-4}\sqrt{E}. \tag{8a}$$

Allowance is made in (8) and (8a) for heating of the cathode through conversion of the potential and kinetic energy of ions and of electrons from the tail of the Maxwellian distribution bombarding the cathode. The heat flux into the electrode is calculated on the assumption that the current in the cathode spot is distributed according to a Gaussian law and that the electrode itself, in comparison with the effective size of the source of heat, is a semiinfinite body. The cathode is cooled through the evaporation and removal of material from the cathode region (G_{er}, experimentally[1] determinable) and through losses to radiation according to the Stefan–Boltzmann law. The cathode is also cooled as a result of emission of electrons. The energy carried away from the cathode by the electrons is taken to be the work function φ reduced[10] by the Schottky effect ($T_c\sim$ 3600–4000°K). The electric field is determined from the equation

TABLE A

	i_0, A/cm²	T_C, °K	w_e, eV	α_∞	s	f_w
First method	$5\cdot10^4$	3720	1.22	0.11	0.456	0.7
Second method	$5.63\cdot10^4$	3737	1.33	0.1	0.464	1

$$E^2 = 7.57\cdot10^5 (u_c)^{1/2} i_0 \Big[(1-s)(1.845\cdot10^3 A_i)^{1/2} - s - \Big(\frac{2e}{m_e}\Big)^{1/2} \frac{en_i}{2i_0}\frac{kT_e}{u_c^{1/2}}\big(1-e^{-eu_c/kT_e}\big)\Big]. \tag{9}$$

Equation (9) is essentially the Mackeown equation including the effect of space charge of the electrons moving from the plasma to the cathode. In the collisionless sheath the plasma electrons are assumed to follow a Boltzmann distribution ($u_c \sim 15$ eV, $w_e \sim 1$ eV). This term can be neglected if $w_e/(w_i e u_c)^{1/2} \ll 2.7\cdot10^3$.

The degree of ionization α in the equilibrium region is determined from the Saha equation

$$3.8\cdot10^{-10}\frac{10^{A_s - B_s/T_k}}{(w_k w_i)^{1/2}} = \frac{1-\alpha}{\alpha^2}(w_e)^{3/2} e^{-3u_i/2w_e}. \tag{10}$$

When Eqs. (1) and (2) are written in dimensionless form (below) we see that if

$$\frac{(1+\theta)D_{ia}}{\beta n_0^2 l_i^2} \ll 1, \tag{11}$$

the ion density gradient occurs mainly at a distance from the cathode equal to the ion mean free path l_i. The ion density does not vary with increasing distance from the cathode above this value and is equal to the equilibrium value. In this case the flux of ions to the cathode can be determined in two ways. Assuming that the hydrodynamic relation holds up to the wall (x = 0), by solving the system of equations (1)–(10), we can determine the ion flux from the boundary condition of Eq. (2), which depends on the density at the wall n_w. The other method is as follows. Without considering the processes occurring in a distance of one mean free path, we regard the ion density as constant and equal to the equilibrium value up to the wall. Since the ion distribution function is a Maxwellian[6] it follows that the ion flux is given by $n_0 v_{iT}/4$, and Eqs. (1) and (2) in the general system can be dropped.

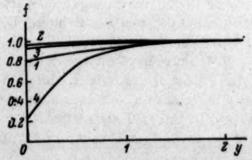

Fig. 1. Ion density distribution in the cathode plasma f as a function of distance y.

TABLE 1

2	10^{19}	10, 0.1	10^4	3
3	10^{19}	0.1	10^6	10
4	10^{19}	0.1	10^5	10

The system of equations for a copper cathode was solved by these two methods for a current of 200 A. The results of the calculations are shown in Table A. Here, $f_w = n_w/n_0$. The results given by the two methods agree and the ion density at the wall as determined by the first method is close to the equilibrium value. Accordingly, system (1)–(10) is simplified when (11) is satisfied.

Before discussing the solution of the system of equations let us estimate the influence of excited atoms and multiply charged ions in the relaxation region and consider Eqs. (1) and (2) in more detail allowing for the excitation process.

The presence of excited atoms in the cathode region can result in stepwise ionization and thus constitutes an additional source of ions. It can also reduce the energy of the plasma electrons when the excited atoms move to the cathode or pass through the outer boundary of the relaxation region. The energy flux carried away to the cathode by the excited atoms, of density n^*, we estimate, for example, from the expression $(n^* v_{iT} u^*/4)$ (the energy flux through the outer boundary of the relaxation region will be still smaller since $v_{iT} \gg u$). Comparing this expression with the first term on the right side of (3) gives $[2w_e(1+\alpha\xi)/(1-s)u^*]\,n_0/n^* \sim n_0/n^*$. The energy carried away by excited atoms thus becomes significant only when n^* is close to n_0. On the assumption that the excited atoms obey a Boltzmann distribution ($w_e \sim 1$ eV, $n_a \sim 10^{20}$ cm⁻³),

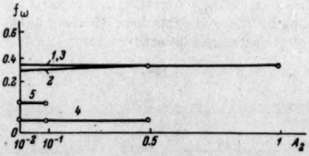

Fig. 2. Variation of ion density at wall f_w with density of excited atoms A_2 at θ = 10.

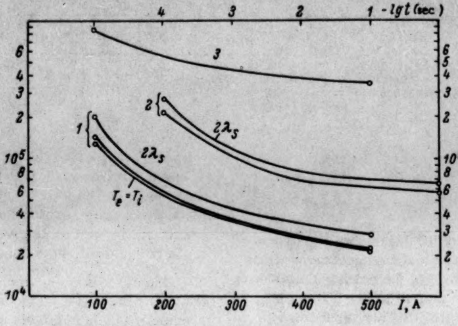

Fig. 3. Variation of current density i_0 with total current I (curves 1) and with discharge duration (curves 2). Curve 3 shows the variation of the electric field E (V/cm) with total current.

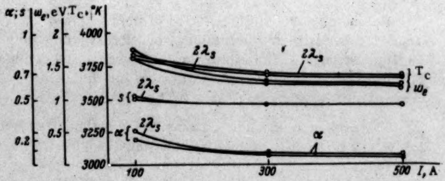

Fig. 4. Variation with the total current I of degree of ionization α, current fraction carried by electrons s, electron energy w_e, and cathode temperature T_c.

the quantity n* can be estimated from $n^*/n_a \sim \exp(-u^*/w_e) \sim 10^{-2}$. It follows, taking $\alpha \sim 0.1$ (see the Table 1), that $n_0/n^* \gg 1$. We note that as a rule it is mainly ion lines that are observed in experimental studies of cathode spots on copper.

With the aim of determining how the quantities n*; D_{ia}; i_e; T_e; n_0 affect the nonequilibrium region we write equations like (1) and (3) in dimensionless form, remembering that electrons leave the beam through excitation of neutrals, stepwise ionization, direct ionization, and by scattering by charged particles. Ions are generated as a result of stepwise and direct ionization:

$$\frac{d^2f}{dy^2} = A_1[(1+\theta)(1-f) - A_2]\exp\left\{-\left[(1+\theta)(1-f) + \frac{f\sigma_k}{\sigma_i+\sigma^*} - A_2\left(1-\frac{\sigma_i^*}{\sigma_i+\sigma^*}\right)\right]By\right\} - A_2A_3\exp\left\{-\left[(1+\theta)(1-f) + \frac{f\sigma_k}{\sigma_i+\sigma^*} - A_2\left(1-\frac{\sigma_i^*}{\sigma_i+\sigma^*}\right)\right]By\right\} + A_4\frac{df}{dy} - f(1-f^2). \tag{12}$$

The boundary conditions are $df/dy/_{y=0} = A_5 f_w$, $df/dy|_{y=\infty} = 0$, where $A_1 = \sigma_i i_e/e\beta n_0^2$, $f = n_i/n_0$, $A_3 = i_e\sigma_i^*/e\beta n_0^2$, $B = (\delta_i + \sigma^*)(D_{ia}/\beta)^{1/2}$, $A_4 = i_0 G_{er}/\mathrm{Im}\, n_0^2(\beta D_{ia})^{1/2}$, $A_5 = v_{iT}/2n_0(\beta D_{ia})^{1/2}$, $y = (\beta n_0^2/D_{ia})^{1/2}x$. The value T_e is chosen to make the degree of ionization unity at infinity. The remaining parameters are prescribed in the following ranges: $i_e = 10^4$–10^6 A/cm², $D_{ia} = 0.01$–10 cm²/sec, $n_0 = 10^{18}$–10^{20} cm^{-3}, $A_2 = n^*/n_0 = 10^{-2}$–1. The results of calculations based on Eq. (12) are shown in part in Figs. 1 and 2 and in Tables 1 and 2. These results show that the ion density distribution at the cathode is not greatly affected by the direct and stepwise ionization. This indicates the relatively small role played by the beam in the ionization process and the dominant role of thermal ionization. The ion density at the wall f_w begins to depart significantly from the equilibrium value only at relatively large T_e ($\theta = 10$) and small D_{ia}. The diffusion coefficient has a significant effect when $D_{ia} \le 0.1$. Reducing D_{ia} from 0.1 to 0.01 cm²/sec reduces the degree of ionization at the wall f_w (at y = 0) from 0.55 to 0.25. An estimate of the effect of the rate of flow of vapor from the cathode region on the ion density distribution by eliminating the corresponding term ($A_4 = 0$) in Eq. (12) shows that this effect can be neglected in the investigated range of parameters.

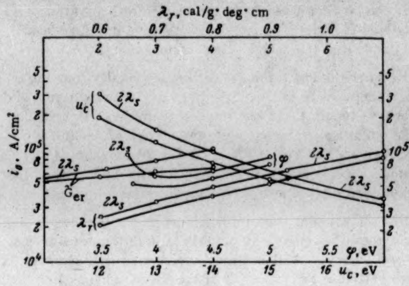

Fig. 8 Effect on current i_0 of varying the work function φ, the thermal conductivity λ_T, the heat of evaporation λ_s, and the mass flow rate G_{er} of cathode material.

Finally, let us determine the effect of multiply charged ions on the ion current and the energy of the electrons in the cathode region. The presence of multiply charged ions in the electrode regions is noted in refs. 11 and 12. We estimate the contribution of such ions in terms of the equilibrium value in the charged-particle balance for an arc discharge in copper, assuming that the charged particles are produced in the form of singly (n_i), doubly (n_{2i}), and triply (n_{3i}) charged ions. The degree of ionization $\alpha = n_e/(n_a + n_e)$, where $n_e = n_i + 2n_{2i} + 3n_{3i}$ by virtue of quasineutrality. Assuming also constancy of pressure, we determine the total density $n_n = P/kT = \theta n_e + n_i + n_{2i} + n_{3i} + n_a$. The densities of ions of all forms can be obtained from the following relationships: $n_e n_i/n_a = A_1^0$, $n_e n_{2i}/n_i = A_2^0$; $n_e n_{3i}/n_{2i} = A_3^0$, A_1^0, A_2^0, A_3^0 are equilibrium constants, dependent on the electron energy w_e. The heating of the plasma electrons we determine for simplicity by assuming that the beam electrons dissipate their energy solely on ionization and that the electron gas is cooled via the electron current through the outer boundary of the relaxation region.

Under these assumptions, when $T \sim 4000$°K, $s = 0.5$, $n_n \sim 10^{20}$ cm^{-3} we find that the various densities are $n_i \approx 1.1 \cdot 10^{19}$ cm^{-3}, $n_{2i} \approx 1.65 \cdot 10^{18}$ cm^{-3}, $n_{3i} \approx 1.4 \cdot 10^{14}$ cm^{-3}, $n_e \approx 1.4 \cdot 10^{19}$ cm^{-3}, and $w_e \approx 3.3$ eV. A calculation carried out under these assumptions for the case of singly charged ions alone gives $w_e \approx 3.64$ eV. Thus, the presence of multiply charged ions has little effect on the electron energy and on the ion current ($n_i \approx n_e$).

DISCUSSION OF SOLUTIONS

Equations (1)-(10) are solved for the cathode region of an arc discharge on copper subject to (11) and the conditions $T_e = T_i \neq T_c$ and $T_i = T_c \neq T_e$ for currents in the range from 100 to 500 A and for various times of burning of the discharge. The room-temperature values of the thermophysical constants are used in all the calculations. Deviations of these constants from these values will, however, be analyzed in detail. Figure 3 shows plots of current density i_0 versus the total current I for a stationary spot (curves 1) and plots of i_0 versus discharge duration for I = 200 A (curves 2). The results of solving the equations pertain to the condition $T_i = T_c$. The curve corresponding to $T_i = T_e$ is shown for comparison; here and below the legend $T_i = T_e$ will be appended to such curves. In like manner, curves to which the legend $2\lambda_s$ is appended correspond to solving the system of equations for a heat of evaporation λ_s equal to twice the room-temperature value. It can be seen from Fig. 3 that the current density i_0 in a discharge with lifetime of 10^{-3} sec and longer is close to the value of i_0 in the steady-state regime. Varying the total current I from 100 to 500 A varies the steady-state current density from $1.4 \cdot 10^5$ to $2 \cdot 10^4$ A/cm^2, i_0 varying very slightly with ion temperature.

It is interesting to note that an analysis of the areas of cathode spots on copper, measured using an SFR-1 high-speed photorecorder with a special optical attachment in the time loop regime,[9] shows that the current density in stationary and almost stationary spots varies from $3 \cdot 10^4$ to 10^5 A/cm^2 for current variations from 200 to 300 A. This current is distributed over a group of spots. As the distance between individual spots within this group is much smaller than the diameter of the spots, the group can be regarded in the calculations as constituting a single cathode spot.

Figure 4 shows the variation with total current I of the degree of ionization α, the fraction of the current carried by electrons s, the electron energy w_e, and the cathode temperature T_c. It can be seen that these quantities vary but little with I; their mean values are: $T_c \sim 3800$°K, $s \sim 0.5$, $\alpha \sim 0.1$, $w_e \sim 1$ eV. Figure 5 shows these quantities vary with the lifetime of the cathode spot

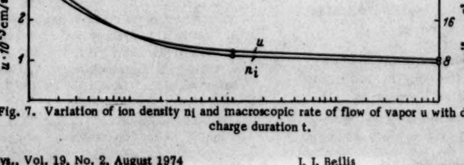

Fig. 7. Variation of ion density n_i and macroscopic rate of flow of vapor u with discharge duration t.

t. It can be concluded from the curves of Fig. 5 that α, s, w_e, and T_c scarcely vary with time and can thus be determined from the steady-state expressions.

Figures 6 and 7 show how the ion density and the macroscopic rate of flow of vapor vary with current I and discharge length t. It can be seen from these figures that these quantities vary but slighlty and are of order respectively, $n_i \sim 2 \cdot 10^{18}$-10^{19} cm^{-3}, $u \sim 10^3$ cm/sec. Conditions $u \ll v_{iT}$ and (11), allowing for the data on the other parameters cited above, are thus satisfied.

At the present time information on the thermophysical properties of electrode materials at high temperatures is very sparse.[13] Calculations are accordingly carried out to estimate the influence of the thermophysical parameters and also the effect of inaccuracy in measurements of the work function, the cathode drop, and the flow rate of electrode material on the current density in the cathode spot i_0. These calculations show (Fig. 8) that inaccuracy in measurements of these quantities introduces an error approximately equal to that obtained in the experimental determination of the current density. The rest of the parameters of the spot are also not affected greatly.

The results contained in Fig. 8 are of special interest when it is remembered that the view hitherto expressed in the literature is that it is the thermophysical parameters and the emission constants that have the decisive influence on the processes in the cathode spot. It would appear that this conclusion has been reached on the basis of an analysis of individual equations, which, as a rule, have not been solved simultaneously. The results of solving the system of equations simultaneously show that, despite variation of the thermophysical and emission constants, the processes in the cathode spot adjust themselves in such a manner that the current density and the other parameters of the spot do not vary significantly.

An analysis of the system of equations for copper shows that the main loss of energy at the cathode is due to thermal conduction. The emission of electrons from the cathode is mainly determined by the thermionic mechanism together with the Schottky effect. Solving the system of equations with this mechanism of emission gives results for all parameters of the discharge that are close to the values cited above. For example, the difference between the current density for I = 200 A is as follows: $5.63 \cdot 10^4$ and $5.7 \cdot 10^4$ A/cm^2; for I = 300 A the difference is $3.57 \cdot 10^4$ and $3.63 \cdot 10^4$ A/cm^2. Ionization and removal of energy due to the electron current at the outer boundary of the relaxation region are the main processes responsible for the loss of energy in the cathode plasma. The removal of vapor from the cathode region has no effect on the ion current, although it must be taken into account in the energy balance of the cathode plasma. The parameter values and the physical processes in the cathode spot vary very slightly with total current and discharge conditions. Preliminary studies of the system of equations for tungsten have shown, however, that the solution may depend significantly on the vapor pressure.

In conclusion we note the following. An expression has been obtained by Kesaev[2] for estimating the minimum current density i_{0m} in a cathode spot on a massive cathode. An estimate of i_{0m} for a cellular current gives $i_{0m} \approx 3 \cdot 10^7$ A/cm^2 and for $I \approx 200$ A $i_{0m} \approx 5 \cdot 10^5$ A/cm^2. This result differs substantially from the results of our calculations (Fig. 3). This discrepancy may be explained by the use in ref. 2 of a value of s ($s \approx 0.95$) that is much too high in comparison with the results on Fig. 4.

It would appear that the assumptions used in Kesaev's calculation by the method of signatures on thin films do not reflect the phenomena taking place in a real cathode spot for the following reason. Calculations of the temperature fields[14] for a wide range of current densities show that the dimensions of the melting zone do not greatly exceed (by less than a factor of 2) the dimensions of the zone heated to the boiling point. As it is precisely in the latter zone that intense evaporation and electron emission take place, it follows that assuming the cathode spot to be a point source of heat may lead to erroneous results. For this reason, evidently, the use of the melting point T_{melt} in Eq. (45.4) of ref. 2 is also erroneous, since the width of the signature δ, determined with a certain error, may in fact characterize an isotherm with a temperature greater than T_{melt}. Increasing the temperature in Eq. (45.4) by a factor of 2 increases the fraction of the current carried by ions by a factor of 2 for δ = const.

Finally, with very thin films ($d \sim 0.025\,\mu$) the energy removed by thermal conduction may be negligible in comparison with the energy expended in removing material from the cathode region. This can be seen by comparing the energy flux falling upon a film cathode $(1-s)I(u_c + u_i - \varphi)$ with the energy flux removed from the cathode region (the requisite numerical values of the quantities appearing in the equations may be taken from ref. 2). The fluxes become comparable when s = 0.8, while[2] for s = 0.95 the energy flux from the cathode begins to exceed the incoming energy flux.

The author wishes to thank G. A. Lyubimov for discussion.

---

1) The equations given here also allow for processes occurring in the cathode plasma.

Emission processes at the cathode of an electric arc

I. I. Beilis

Academy of Sciences of the USSR, Moscow

(Submitted January 26, 1973; resubmitted July 26, 1973)
Zh. Tekh. Fiz., 44, 411-418 (February 1974)

The energy distribution of the electrons emitted from the cathode of an arc is calculated as a function of electric field and cathode temperature. Certain conclusions are reached concerning the emission mechanism in cathode spots for copper. In long-lived and slowly moving spots electrons are emitted by the thermionic mechanism with the Schottky effect. Contemporary experimental data on the current density for rapidly moving spots cannot be explained on the basis of thermionic-field (T−F) emission. The cooling and heating of the cathode as a result of electron emission (the Nottingham effect) are discussed. The presence of a minimum value of work function for which a long-lived spot can exist on a copper cathode is noted. An estimate is given for the effect of any inaccuracy in the calculation of the electric field.

The basic assumption in most theories of the electric arc is that emission processes at the cathode are responsible for the charge carriers in the cathode region.[1,2] The primary difference between theories lies in the preference given to one or other of the emission mechanisms: thermionic emission, field emission, or thermionic-field (T−F) emission. The physics of each of these electron-emission mechanisms and the derivation of appropriate relations are given in detail in refs. 3-6. Accordingly, we shall not analyze the familiar relationships here but shall only make a preliminary study of specific relationships used to describe the processes occurring at the cathode.

We shall not specify any particular type of emission and shall assume for generality that electrons can be emitted by the cathode from any energy level in the conduction band. The electron energy distribution in ε_n in the metal is described by Fermi−Dirac statistics and the probability that an electron will tunnel from the metal through the potential barrier at the metal−vacuum boundary is characterized by the transmission coefficient.[3-5]

In this case, as shown in refs. 3-5, the emission current density can be calculated from the relationship

$$i_e = e \int\limits_{-\infty}^{+\infty} N_e(\varepsilon,\ T_k)\, D(\varepsilon,\ E)\, d\varepsilon. \tag{1}$$

Applying Fermi−Dirac statistics for the electron flux falling on unit area of the barrier, N_e, we have

$$N_e(\varepsilon,\ T_k) = \frac{4e\pi m_e kT_k}{h^3} \ln\left[1 + \exp\left(-\frac{\varepsilon}{kT_k}\right)\right], \tag{2}$$

where e is the electron charge, $\varepsilon = \varepsilon_n - \varepsilon_0$, ε_0 is the Fermi level, T_k is the cathode temperature, E is the electric field, m_e is the electron mass, and k is Boltzmann's constant.

Let us consider the transmission coefficient D. The theory considered in refs. 3-5 holds for the one-dimensional case and is based on the free-electron model. This model gives several different expressions for D depending on additional assumptions used in the derivation.[5,8] As noted in refs. 4 and 6, the results of calculating D via these expressions differ by a factor of 2. On the basis of the generalized WKB method Kemble[7] obtains an expression for D which differs from those mentioned above in that it describes the emission process by one relation both for tunneling electrons and for electrons above the barrier. However, as correctly noted by Itskovich,[6] it is precisely near the summit of the barrier, the features of which were taken into account by Kemble, that the potential distribution used by Kemble is invalid. Accordingly, any refinement in the calculation of D within the framework of the free-electron model that does not allow for an arbitrary dispersion law, as noted by Itskovich,[6] cannot increase the accuracy of results deriving from this model.

In this connection a theory of electron emission has been constructed by Itskovich[6] for the case of an arbitrary dispersion law. The results obtained by Itskovich show that allowing for the law of dispersion in the theory of electron emission leads to the familiar relations obtained earlier[3-5] but with a slightly increased value of the work function φ. Thus, allowing for a complex dispersion law is equivalent to making a certain correction to the value of the work function φ. As noted in refs. 6, 9, and 10 this correction has a noticeable effect only for the noble metals and depends on the topology of the Fermi surface. Accordingly, in the case of copper under arc conditions there is no need to allow for the effect of a complex dispersion law.

An original attempt to construct a theory of emission free from the essentially classical approach of refs. 3-6 (e.g., the existence of a potential barrier at the metal−vacuum boundary, the free-electron model) was made by Brodskii and Gurevich.[11] The use of the threshold approximation developed by these authors depends on the existence of a small parameter connected with the relatively small range of energies of emitted electrons, the concepts of the theory of potential scattering lying at the basis of the proposed model. A clear explanation is given in ref. 11 of the processes of electron emission at large transmission coefficients ($D \sim 1$) on the basis of a comparison of the wavelength of emitted electrons with the thickness of the potential barrier. It turns out that the emission process in this case does not depend on the shape of the potential barrier and that the expression for D is dictated solely by classical model concepts. Accordingly, varying the specific form of this expression cannot have a decisive effect on the results of emission calculations.

Unfortunately, no final relationships are obtained in ref. 11 by means of which the process of T−F emission, considered below, can be calculated. Accordingly, in performing our emission calculations, we may utilize Eq. (1), which has been experimentally confirmed by Andreev[12] (in the ranges of E and T_k considered below), while the specific form of the expression for D may be chosen solely from considerations of convenience in the ensuing calculations.

On the basis of the above we shall analyze the emission processes on the cathode utilizing the simplest and most frequently employed expression for the transmission coefficient first proposed by Bethe and Sommerfeld:[5]

$$D(\varepsilon, E) = \exp\left[-\frac{6.85 \cdot 10^7 (\varphi - \varepsilon)^{3/2} \theta(\tilde{y})}{E}\right], \tag{3}$$

where $\tilde{y} = (e^3E)^{1/2}/|\varepsilon|$ and $\theta(\tilde{y})$ is the Nordheim function.

An expression for $\theta(\tilde{y})$ in analytic form is obtained in ref. 13:

$$\theta(\tilde{y}) = 1 - \tilde{y}^2\left\{1 + \mu \sin\left[\frac{1-\tilde{y}}{2}\right]\right\},$$

where μ is a variable coefficient. Choosing the expression for the transmission coefficient in the Bethe–Sommerfeld form is also convenient in that it permits comparison of our results with the results of similar calculations by Dolan and Dyke,[14] where D has the form (3) but which were carried out for a different range of parameters.

Thus, utilizing (1), (2), and (3), the expression for the emission current density has the form

$$i_e = \frac{4e\pi m_e kT_k}{h^3} \int\limits_{-\infty}^{+\infty} \frac{\ln\left[1 + \exp\left(-\frac{\varepsilon}{kT_k}\right)\right] d\varepsilon}{\exp\left[\frac{6.85 \cdot 10^7 (\varphi - \varepsilon)^{3/2} \theta(\tilde{y})}{E}\right]}. \tag{4}$$

The emission process described by (4) can have the character of thermionic emission, field emission, or T−F emission depending on the ratio of the cathode temperature T_k and the electric field E. It is known[4] that the existence of a specific mechanism of emission is determined by the corresponding distribution in energy of the emitted electrons. In a qualitative study of the effect of varying T_k and E it is thus of considerable interest to establish how the energy distribution of the emitted electrons varies as a function of the two variables T_k and E. Such a study was made by Dolan and Dyke.[14] The calculations carried out by these authors pertain, however, to a very narrow range of variation of T_k and E and do not give a complete description of the quantities of interest in the range of values of E and T_k characteristic of arc discharges.[2]

In this connection we cite below the results of calculations carried out over a wider range of variation of the parameters. The method of calculation is similar to that of Dolan and Dyke[14] but differs in that the results are not presented in relative units, but in the form of plots of $i_e(\varepsilon)$, the dependence of the emission current density on the energy of the electrons in the metal. This also makes it possible to estimate the emission current density as a function of the specific values of E and T_k.

An expression for the emission current density $i_e(\varepsilon)$ as a function of electron energy ε is readily obtained from (1) on inserting (2) and (3) in the form

$$i_e(\varepsilon) = \frac{4e\pi m_e kT_k}{h^3} \frac{\ln\left[1 + \exp\left(-\frac{\varepsilon}{kT_k}\right)\right]}{\exp\left[\frac{6.85 \cdot 10^7 (\varphi - \varepsilon)^{3/2} \theta(\tilde{y})}{E}\right]}. \tag{5}$$

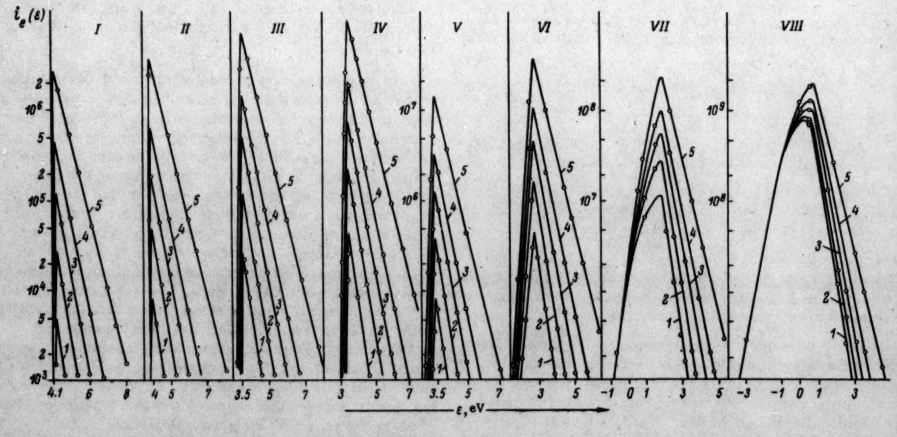

Fig. 1. Emission current density $i_e(\varepsilon)$ versus energy of emitted electrons (φ = 4.5 eV) for various values of the electric field and cathode temperature. The emission density (A/cm²) is plotted along the ordinate axis; the energy of emitted electrons (in eV taken from the Fermi level ε = 0) is plotted along the abscissa axis. Curves I-VIII correspond to the following values of the electric field (V/cm): $10^6, 2\cdot10^6, 5\cdot10^6, 7\cdot10^6, 10^7, 2\cdot10^7, 5\cdot10^7, 10^8$; these values of the electric field correspond to the following values of φ_S(eV): 4.12, 3.96, 3.65, 3.5, 3.3, 2.8, 1.81, 0.7. Curves 1-5 correspond to the following cathode temperatures: 3500, 4000, 4500, 5000, 6000°K.

Expression (5) is essentially the product $N_e(\varepsilon, T_k)D(\varepsilon, E)$ and so represents the distribution in energy of the flux of electrons that have leaked through the potential barrier with a probability $D(\varepsilon, E)$. The calculations are carried out in the ranges $T_k = 3500$–6000°K, $E = 10^6$–10^8 V/cm for $\varphi = 4.5$ eV. The results are presented in Fig. 1 in the form of a series of curves. For each curve I–VIII the caption cites the respective electric field and the work function φ_S, where $\varphi_S = \varphi - (e^3E)^{1/2}$ is the work function as reduced by the Schottky effect. The quantity $i_e(\varepsilon)$ is plotted along the ordinate axis and ε along the abscissa axis, where $\varepsilon = 0$ denotes the position of the Fermi level.

It is evident from Fig. 1 that increasing the electric field shifts the curves into a region of negative values of ε, indicating the increasing role of field emission. With increasing cathode temperature the number of electrons excited to higher levels increases, with the result that the T–F character of the emission becomes more clearly expressed. These features quite clearly demonstrate the transition from the one type of emission to the other and confirm the previous results.[14] A characteristic of the curves of Fig. 1 is that the position of the maximum of each of the curves corresponds to an electron energy equal to φ_S. An exception is the case $E = 10^8$ V/cm and $T_k \leqslant 5000$°K, which is displaced towards smaller energy values.

For fields $E \leqslant 10^7$ V/cm the number of emitted electrons with energy less than φ_S is negligible for any cathode temperature in the investigated range of variation of E and T_k. Even when $E \sim 5 \cdot 10^6$ V/cm and $T_k \sim 4000$°K the emission current density can reach a value of 10^5 A/cm^2. An interesting and very evident fact that can be seen from the curves of Fig. 1 is that the Nottingham effect, i.e., heating of the cathode through the emission of electrons with energy less than the energy at the Fermi level, begins to manifest itself when $E \sim 5 \cdot 10^7$ V/cm and becomes significant when $E \sim 10^8$ V/cm. It thus turns out that the Nottingham effect shows up in the investigated range of temperatures only when the height of the potential barrier is small ($\varphi \sim 0.7$ eV, Fig. 1). The emission current density can then exceed 10^9 A/cm^2.

On the whole one can conclude from an analysis of the curves of Fig. 1 that the Nottingham effect, which manifests itself only under conditions characteristic of the prebreakdown and spark stages of the discharge[15] ($E \sim 10^8$ V/cm; $i_e \sim 10^8$–10^9 A/cm^2), will play a negligible role in the thermal balance for the cathodes of an arc discharge[1,2] ($d\dot{J}/dt < 10^7$ A/sec). At the same time, in calculating the effect of cooling of the cathode through the emission of excited electrons one can assume that the electrons carry away from the cathode an energy of about φ_S when $E \leqslant 2 \cdot 10^7$ V/cm (Fig. 1). The contribution of tunneling electrons to the total emission flux, as follows from the figure, is probably not large.

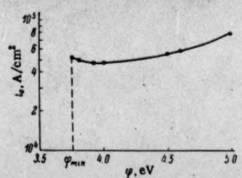

Fig. 2. Variation of current density in cathode spot with work function of cathode material. φ_{min} is the minimum work function of a copper cathode for which stationary existence of spot is possible.

The results obtained above can be used directly to study the parameters of the cathode region of the arc. In refs. 16 and 17 a study is made of a system of equations describing[2] the long-lived ($t \leqslant 10^{-4}$ sec) spots on a copper cathode and incorporating Eq. (4), and the dominance of thermal emission of electrons from the cathode was pointed out. Considering the range of values of E and T_k obtained when solving this system of equations (for completeness the results of the calculations of ref. 16 are presented in Table 1) it is not hard to see that this conclusion follows from a consideration of the results presented in Fig. 1 and described above. Table 1 also lists the values of the degree of ionization α, the electron energy w_e, the densities of charged and neutral particles, n_i and n_a respectively, in the cathode plasma, and the current density i_0 and the fraction of the current carried by electrons s obtained through solving the system of equations of ref. 16. Evidently the values of these parameters calculated allowing for Eq. (4) almost coincide with the values calculated allowing for the thermionic mechanism of electron emission with the Schottky correction.

The presence of the thermionic mechanism of emission in cathode spots indicates that the only effect of the electric field at the cathode is to change the effective value of the work function by an amount $\Delta\varphi = (e^3E)^{1/2}$ due to the Schottky effect. Thus, for example, doubling the field E changes $\Delta\varphi$ by a factor of $\sqrt{2}$. The resulting change of i_0, the most important parameter characterizing the cathode

spot, is insignificant, as follows from the curve of $i_0(\varphi)$ of ref. 16 (Fig. 2). An analysis of the curve of Fig. 2 shows that the possible inaccuracy in the determination of E connected with the use of the Mackeown equation[18] will not introduce any appreciable error into the determination of the current density in long-lived spots.

A very interesting result is the minimum value of the work function for which the solution of the system of equations of ref. 16 still exists; for copper this minimum value is $\varphi_{\min} \sim 3.75$ eV (Fig. 2). Below this value, i.e., for $\varphi < \varphi_{\min}$, the solution of the system becomes unstable. A detailed study of this system of equations has shown that the absence of a solution (with acceptable accuracy) for $\varphi < \varphi_{\min}$ is not only due to the processes taking place at the surface of the solid (emission of electrons and variation of thermal regime of cathode due to variation of emission cooling effects), but also to the cathode plasma. Thus, it turns out that as φ is reduced the temperature required to achieve the previous emission current density is decreased significantly (for $\varphi = 4.5$ eV $T_k = 3737$°K, for $\varphi = 4.0$ eV $T_k = 3314$°K); as a result, the density of the particles (including charged particles) in the cathode plasma is also reduced. When φ is equal to $\varphi_{\min}$, the ion current falls to a value at which the corresponding heat flux is insufficient to heat the cathode to the temperature required to obtain the corresponding emission current from the cathode. In this case the system of equations for the cathode region will have no solution.

The presence of a regime (characterized by the minimum value of the work function $\varphi_{\min}$) in which long-lived cathode spots can exist in arcs with an evaporating cathode and also the relatively weak variation of the current density in the cathode spot with work function (greater than $\varphi_{\min}$) indicate that this type of discharge is regulated mainly by the thermal regime, which adjusts itself during the burning of the arc in the cathode spot.

The position is quite different for rapidly moving ($v \sim 10^3$ cm/sec) cathode spots. The lifetime of such spots[1] $t \sim 10^{-6}$–10^{-5} sec. In such a short time the cathode region in the spot can be heated to temperatures at which T−F emission is possible only if the current density i_0 is sufficiently large. Table 2 shows the spot temperatures for various individual values of i_0 (top row) and times t calculated through the equation of ref. 16 for a stationary source of heat and ignoring the erosion of cathode material for copper (current strength $\tilde{J} = 10$ A, $s = 0.5$, cathode fall $u_c = 15$ V). It can be seen from the table that significant heating of the cathode in rapidly moving spots can occur when $i_0 > 10^6$ A/cm^2. Remembering that it is possible that $\tilde{J} < 10a$, $s > 0.5$ in such spots and that the velocity is in fact not zero, it follows that we must have[1] $i_0 \gg 10^6$ A/cm^2. The hitherto experimentally measured values of i_0 in arc spots correspond to $i_0 \leqslant 10^6$ A/cm^2. Furthermore, the measurements of Golub' et al.[19] show that in fast spots, i_0 may be $\sim 10^4$–10^5 A/cm^2. It is also pointed out by these authors that the previously obtained values of i_0 in fast spots may be too high through the use of recording apparatus with a low light sensitivity (in the case of the optical method of measurement).

Such a low current density cannot, of course, be explained on the basis of T−F emission (Fig. 1) or on the basis of pure field emission. In the latter case[1] one would require $i_0 > 10^7$ A/cm^2. It can thus be concluded from the present calculations (Fig. 1, Table 2) that contemporary experimental data on the current density for short-lived, rapidly moving spots are not described by the traditional ideas of existing emission mechanisms (which permit calculation of the mean electron emission current), and that the thermal processes determining the mean temperature of the cathode in the spot are not significant as far as the maintaining of this type of discharge is concerned.

Time dependence of ion currents produced through surface ionization. Ionization of Ba on the (111) face of iridium

É. Ya. Zandberg, E. V. Rut'kov, and A. Ya. Tontegode

A. F. Ioffe Physicotechnical Institute, Leningrad

(Submitted June 18, 1973)
Zh. Tekh. Fiz., 44, 419-423 (February 1974)

The time required to establish the steady-state current (i.e., the equilibrium coverage of the emitter with atoms of the material being ionized) subsequent to a change of temperature of the emitter is studied for a constant flux of particles. A connection is found between the required expectation time and the heats of evaporation of atoms and ions from the surface of the emitter, the emitter temperature, and the amount by which it is changed. It is shown that for large heats of evaporation of particles from the emitter the temperature dependence of the ion currents and of the neutral flux from the surface significantly distorts the time dependence of these quantities. The results are illustrated by the ionization of Ba on the (111) face of iridium. The heats of evaporation of atoms and Ba$^+$ ions from the (111) face of Ir are determined and the manner in which the atomic and ionic lifetimes vary with temperature is established.

The temperature dependence I(T) of ion currents produced by ionization on the surface of a solid of a constant flux of particles yields information on many physicochemical characteristics of the interaction of the particles with the solid.[1]

It has been observed[2,3] in studies on the ionization of alkali metal atoms that at low emitter temperatures the time to establish the steady-state current subsequent to a change of temperature is very much greater than the time to establish the temperature. For slow time dependences of the currents one records the transient currents corresponding to arbitrarily chosen expectation times.[3] In principle the time dependence of the currents introduces an error into the measured threshold temperature for ionization of easily ionized elements, the most important ionization characteristic of such elements.[3,1]

It follows from ref. 4 that the time variation of the ion currents can be observed in many cases of surface ionization, and the higher the temperature the greater the heat of evaporation of particles from the surface. Ignoring the time dependence of the currents can result in an incorrect determination of those characteristics found from the temperature dependence of currents from surface ionization. Accordingly, the dependence of the ion currents on time and temperature in surface ionization of constant fluxes of particles is a topic worthy of attention.

TIME DEPENDENCE OF ION CURRENTS

The variation of the ion currents with time subsequent to a change in the emitter temperature T is considered by Tontegode and Yusifov.[4]

With a rapid change of T from T_1 to T_2 the equilibrium coverage of the emitter by adsorbed particles for T_1 (which is assumed not to have time to change during the rapid cooling from T_1 to T_2) becomes a nonequilibrium value for the new temperature T_2; with the passage of time it approaches the new equilibrium value. The variation of the coverage with time causes the current to vary.

Assume that a constant flux ν of neutrals impinges upon the emitter and let the equilibrium coverage at T_1 be N_1 and the equilibrium coverage at the lower temperature T_2 be N_2. For simplicity we assume an instantaneous transition from T_1 to T_2. The time variation of the surface coverage N subsequent to switching to T_2 is described by the familiar equation[1]

$$\frac{dN}{dt}+W(T_2)\,N=\nu, \tag{1}$$

where $W(T_2)$, the probability that an ionized particle will be evaporated from the emitter at T_2, is given by

$$W(T_2)=C\exp\left[-\frac{l_+}{kT_2}\right]+D\exp\left[-\frac{l_0}{kT_2}\right]. \tag{2}$$

It is assumed here that the sticking coefficient of the particles to the emitter is unity and that the experiments are conducted under conditions such that the flux of particles does not affect the work function of the emitter for all T. Under these conditions l_0 and l_+ can be regarded as independent of the coverage in the range from N_1 to N_2.

Integrating (1) subject to the boundary condition N = N_1 at t = 0 gives

$$\ln\left(\frac{\nu-N_1W(T_2)}{\nu-N(t)\,W(T_2)}\right)=tW(T_2). \tag{3}$$

It can be seen from (3) that the transition from the steady-state coverage $N_1 = \nu/W(T_1)$ at T_1 to the greater steady-state coverage $N_2 = \nu/W(T_2)$ at T_2 occurs in a time $t = \infty$. Accordingly, let us estimate the time required to reach a coverage close to the equilibrium value N_2. We represent this coverage by $N = \gamma N_2$ (where $\gamma \lesssim 1$) and denote the time required to reach it by t^*. We find from (3)

$$\ln\left[\frac{1-\frac{W(T_2)}{W(T_1)}}{1-\gamma}\right]=t^*W(T_2)$$

$$t^*=\frac{\ln\left[\frac{1}{1-\gamma}\left(1-\frac{W(T_2)}{W(T_1)}\right)\right]}{W(T_2)}. \tag{4}$$

Equation (4) shows that for given l_0 and l_+ and a prescribed value of γ, the time t^* depends significantly on the temperature T_2: The higher the temperatures T_1, T_2 and the smaller the difference between them, the smaller the value of t^*. For given values of T_2 and $T_1 - T_2$ the time t^* will be greater for ionization of materials with greater l_0 and l_+. It also follows from (4) that t^* does not depend on the density of the flux of particles impinging upon the emitter.

Using Eq. (4) we can determine the time t^* required to achieve a coverage which approaches the equilibrium coverage with a given degree of approximation. Accordingly, (4) determines the conditions for obtaining both ion currents with a given degree of approximation to equilibrium and also fluxes of neutrals if the coefficient of ionization $\beta \ll 1$. In the particular cases of $\beta \approx 1$ (easily ionized elements, $W = C \exp[-l_0/kT]$) and $\beta \approx 0$ (desorbed flux of neutrals $W = D \exp[-l_0/kT]$) Eq. (4) simplifies.

Figure 1 shows plots of $t^*(l_+)$ calculated from (4) for ionization of easily ionized elements for various temperatures and the same difference $T_1 - T_2 = 100$°K for $\gamma = 0.9$ and $C = 10^{13}$ sec^{-1}. The dashed line in Fig. 1 corresponds to $t^* = 100$ sec. It can be seen that this expectation time is insufficient to achieve $\gamma = 0.9$ at low T and large l_+; the temperatures at which a time dependence of the currents should be observed increase with increasing l_+. Figure 1 also explains why the currents depend on time only in the region of low threshold temperatures for alkali metals ($l_+ = 2.0$-2.5 eV).

IONIZATION OF Ba ON THE (111) FACE OF IRIDIUM

In this case the ionization potential $\varphi \simeq 5.8$ V (Zandberg and Tontegode[5]) and V = 5.21 volts, so that the condition $e(\varphi - V) \gg kT$ is satisfied and the current should be independent of T at temperatures above threshold. However, as the heat of evaporation of the Ba$^+$ ions must be greater than that of atomic ions of the alkali metals due to the covalent interaction between the s electron of the Ba$^+$ ion and the metal,[6] one can expect a strong time dependence of the currents, which will affect the form of I(T).

We have experimentally measured I(T) for a current of Ba$^+$ ions produced by surface ionization of the (111) face of Ir for a constant flux of Ba atoms and have measured the heat of evaporation of Ba$^+$ ions from this face.

The metal mass spectrometer arrangement described in ref. 7 is used in the measurements; the vacuum system is augmented by a liquid-nitrogen-cooled titanium pump. The pressure of the residual gas under working conditions is $\sim 3 \cdot 10^{-9}$ torr and is distributed over the main components in the following manner: $P_{He} \cong 2.4 \cdot 10^{-9}$ torr, $P_{H_2} \cong 5 \cdot 10^{-10}$ torr, $\bar{P}_{CO} \cong 6 \cdot 10^{-11}$ torr.

The (111) face is brought out to the surface of an iridium ribbon of purity 99.96% by the method described in ref. 5. The ribbon temperature is measured with an optical micropyrometer. The work function of the face is determined from Richardson plots and is 5.78 ± 0.05 V. Barium atoms are supplied to the face from a Knudsen effusion cell filled with metallic barium purity 99.9%. The impurities in the barium are Sr and Mg.

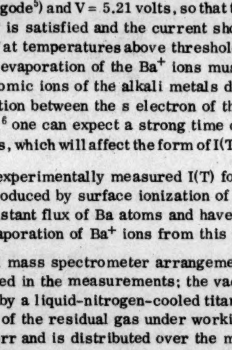

Fig. 1. Expectation time required to achieve a coverage with $\gamma = 0.9$ versus ion heat of evaporation l_+. The various curves correspond to different temperatures T_1, T_2, but with the same (100°) difference $T_1 - T_2$. Temperatures $T_1 - T_2$ (°K): 1) 2000-1900; 2) 1800-1700; 3) 1600-1500; 4) 1400-1300; 5) 1200-1100; 6) 1000-900; 7) 800-700.

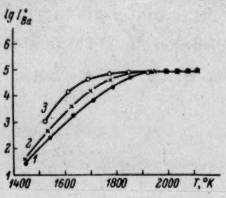

Fig. 2. Experimentally obtained variation of current of Ba$^+$ ions with temperature for ionization of Ba atoms on (111) face of Ir. Different curves correspond to different expectation times: 1) 30; 2) 240; 3) 600 sec. The current is expressed in the usual units.

Figure 2 shows plots of I(T) obtained by reducing the temperature of the iridium in 100° steps for various values of the expectation time at each temperature. At high temperatures the current does not depend on T, as should be the case when $e(\varphi - V) \gg kT$. However, at high temperatures (1950°K) the time dependence of the currents starts to distort the temperature dependence I(T), the more so the smaller the expectation time. At small expectation times the region T < 1950°K may easily be taken to be the threshold region of ionization. This would, however, be a spurious threshold region. This result can be seen from a comparison of the curves of Fig. 2, obtained for various expectation times, and the determinations of the work function for thermionic electrons from the total current (this is possible for T ≥ 1600°K; no reduction of $\varphi_{tot\,T}$ at low T is observed). The threshold region of ionization temperatures is not achieved at the Ba flux density used in the experiments.

The time dependence of the current of Ba$^+$ ions at T ~ 1900°K indicates that the heat of evaporation of Ba$^+$ ions from the (111) face of iridium is large. It follows from Fig. 1 that l_+ must be greater than 5 eV.

We determine the heat of evaporation of Ba$^+$ ions from the (111) face of Ir by two methods: by the method of constant coverage[4] and by the beam modulation technique.[8] In both cases the range of variation of T is 1940-1700°K.

From ref. 4 the ion heat of evaporation is

$$l_+ = \frac{\ln \frac{I_1}{I_2}}{\frac{1}{k}\left(\frac{1}{T_2} - \frac{1}{T_1}\right)}. \qquad (5)$$

where I_1 is the steady-state current at the initial temperature T_1 and I_2 is the nonsteady-state initial current at the final temperature T_2, and the ion lifetime

$$\tau_+(T_1) = \frac{I_2 t}{I_1 \ln\left(\frac{1 - \frac{I_2}{I_1}}{1 - \frac{I_3}{I_1}}\right)}, \qquad (6)$$

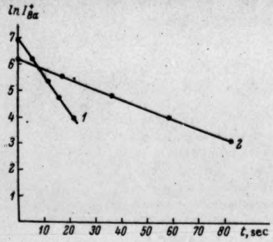

Fig. 3. Variation of current of Ba$^+$ ions with time after interruption of incident flux of Ba atoms. Temperature T (°K): 1) 1910; 2) 1840. The current is expressed in the usual units.

where I_3 is the total current at $T = T_2$ a time t after the temperature is switched to $T = T_2$.

Thirty determinations of l_+ are made for various combinations of T_1 and T_2 in the cited temperature range; we find $l_+ = (5.18 \pm 0.08)$ eV, where the error is the mean-square error. Application of the Schottky cycle gives

$$l_0 = (5.75 \pm 0.09)\ \text{eV}.$$

When determining $\tau_+(T_1)$ from (6) we take different T_2 for each prescribed T_1 and also vary I_3 and the corresponding expectation time t.

At T = 1925°K the ionic lifetime $\tau_+ = (18 \pm 2)$ sec and at T = 1880°K it has increased to $\tau_+ = (36 \pm 3)$ sec. Knowing $\tau_+(T_1)$ and l_+ and the equation $\tau_+ = \tau_{+0} \exp[l_+/kT]$, it is an easy matter to determine the quantity $\tau_{+0} = (5 \pm 3) \cdot 10^{-13}$ sec.

Knowing l_+, l_0, φ, and τ_+ we can find $\tau_0 = \tau_{00} \exp \cdot [l_0/kT]$, the lifetime on the surface of uncharged particles (Ba ions), using the expression[1] for the degree of surface ionization

$$\alpha(T) = \frac{W_+(T)}{W_0(T)} = \frac{Q_+}{Q_0} \exp\left(\frac{\varphi - V}{kT}\right); \tag{7}$$

in this expression Q_+/Q_0 is the ratio of the partition functions of the ion and atom states at temperature T. For various T we find $W_0(T)$ and $\tau_{00} = (10 \pm 8) \cdot 10^{-13}$ sec.

The quantities C and D in (2) are also determined: $C = (2 \pm 1) \cdot 10^{12}\ \text{sec}^{-1}$ and $D = (10 \pm 8) \cdot 10^{11}\ \text{sec}^{-1}$.

By interrupting the flux of the Ba atoms to the Ir surface at fixed temperatures graphs of I(t) are obtained for various T and graphs of $\ln I = f(t)$ constructed (Fig. 3). The quantity $W_+(T)$ is determined from the slopes of the graphs. The results are

$$l_+ = (5.17 \pm 0.10)\ \text{eV},$$
$$l_0 = (5.74 \pm 0.11)\ \text{eV},$$
$$\tau_{+0} = (2.0 \pm 0.3) \cdot 10^{-13}\ \text{sec}.$$

These values agree well with the values obtained by us by the continuous coverage method.[4]

The authors are indebted to N. I. Ionov for discussion.

(Submitted October 25, 1972)
Zh. Tekh. Fiz., 44, 424-428 (February 1974)

A universal plasma ion source is described which can generate both gas ions and metal ions with an output of 1.5 mA at a discharge current below 300 mA and an extraction voltage of 4 kV. The ion source makes use of a hot-cathode Penning discharge. The metal vapor atmosphere with pressures $p \sim 10^{-3}$ torr is obtained by cathode sputtering. The plasma density in the source is increased by a magnetic trap for electrons in the region of the cathode and by electron-optical contraction of the plasma in an inhomogeneous magnetic field generated by superposition of magnetic fields, namely an external magnetic field and the field of the cathode helix. The source unit makes it possible to obtain a discharge in metal vapors in self-sputtering operation at pressures $p \leq 10^{-3}$ torr in the area of the exit opening in place of the pressure $P \geq 10^{-2}$ torr of ref. 1. Ions are emitted from the large surface of the plasma inside the discharge chamber. The outflow of neutral gas is limited by the small opening in the extraction electrode, which is an integral part of the discharge chamber.

INTRODUCTION

An ion source, which can generate ions of an inert gas or of metals, has been developed for research work on the formation of thin films. As with most other ion sources of this type, a hot-cathode discharge is employed. The efficiency of the source is increased by using a Penning discharge. The atmosphere of metal vapor is created by cathode sputtering. Among the possible ways of approaching the problem, there is one which uses the features of the Penning discharge and the features of a sputtered electrode at a negative potential: The sample is in the form of a cylinder which is surrounded by the cathode helix (Figure 1a).

This version of the hot-cathode Penning discharge has the following features.

1. When a homogeneous external magnetic field equal and opposite to the field generated by the cathode helix is applied, a magnetic trap is generated inside the sample electrode (Fig. 2). The result is trapping of electrons in this region; this creates a high degree of ionization inside the sample, where the vapor pressure of the sputtered material is highest.

2. The geometry of the sample electrode increases the efficiency with which the material is used because most of the non-ionized atoms hit the opposite wall of the sample.

3. The outflow of ions from the cylindrical sample causes a longitudinal potential gradient in the sample region and, hence, a gradient in the electron velocity parallel to the axis.[2] Under certain conditions these electron velocities can exceed the random velocities of the electrons. Thus, conditions are obtained for the electron-optical contraction of the plasma in an inhomogeneous magnetic field[3,4] so that the plasma density on the axis is greater than under similar conditions in conventional ion sources of this type (Figure 3). It is possible to obtain ion-output currents (neon and copper) of about 1.5 mA at an extraction voltage of 4 kV and at reduced discharge currents ($J_a \leq 300$ mA rather than $J_a = 1$ A) and external fields of 180 Oe (in place of 500 Oe in similar units).

4. Stable operation of the cathode is guaranteed by the high pressure maintained in the cathode region.

DESIGN OF THE SOURCE

The main components of the plasma chamber are shown in Fig. 1a. The other components (7, 12) of the discharge chamber are provided to keep insulators 9, 13, and 14 from becoming coated by metal vapors.

Double-wall cylinder 15 is the housing of the source. Nonmagnetic stainless steel is the main material of which the unit is fabricated. The insulators are made of aluminum oxide. The magnetic coil 17 is outside the housing.

The power supply is shown in Fig. 4. The source requires a power of 100-200 W under various conditions. The dissipated power is carried away by the cooling water, which circulates in chamber 16 between the walls of the housing.

This design provides reliable operation. The coatings on the surface of the insulators are insignificant: The leakage resistance of the insulators is 500 MΩ at 500 V after 25 hours operation of the source.

CHARACTERISTICS OF OPERATION

In this section we describe source parameters which distinguish the source from that of ref. 1, in which a hot-cathode Penning discharge is also used. In addition, we list data characteristic of the extraction system.

Figure 5 shows the dependence of the discharge current I_a on the external magnetic field (V_a = const). The subscript 1 refers to the conventional ion source of ref. 1, in which a Penning discharge is used (the potential V_s of the sample is equal to the potential V_a of the anode); subscript 2 refers to the version under consideration ($V_s \leq V_{cathode}$). Curves 1 and 2 are obtained with free operation of the cathode (the current drawn from the cathode is limited by the space charge; $I_a \cong I^-$). Curve 2a corresponds to application of a load to the cathode ($I^- \cong I^+$). I^- denotes the electron component, and I^+, the ion component of the discharge current.

1. The minimum voltage required to maintain the discharge is, in the conventional source, 20-25 V ($V_s = V_a$); in the present version the minimum voltage is 50 V ($V_s < 0$).

2. When the external magnetic field H_{ext} = 100 Oe (H_{ext} = 100 Oe = $-H_c$), a minimum of I_a is observed on curve 2, whereas the discharge is cut off on curve 1 (I_a = 0).

3. With H_{ext} = 180 Oe, curve 1 is characterized by saturation of the discharge current J_a, whereas a sharp maximum appears on curve 2. In this case, $I_{a_2} > I_{a_1}$.

4. When the external field is increased further curve 2 tends asymptotically to curve 1.

5. When a load is applied to the cathode (curve 2a), the difference in the characteristics $I_a = f(H)$ disappears: The discharge current reaches its maximum at H_{ext} = 180 Oe and remains constant thereafter, like the current I_{a_1}.

The behavior of this system can be explained as follows: When $H_{ext} = -H_k$, the magnetic mirror which is formed in the cathode area (Fig. 2) prevents the electrons from escaping into the discharge gap. The discharge is interrupted when $V_s = V_a$ (curve 1). The potential gradient inside the negative sample electrode ($V_s \leq V_k$) reduces the reflection of the magnetic mirror, which becomes transparent for a certain group of electrons, i.e., the discharge is ignited ($I_{a\,min} \neq 0$, curves 2 and 2a).

The maximum on curve 2 at H_{ext} = 180 Oe seems to be related to electron-optical plasma contraction. In pro-

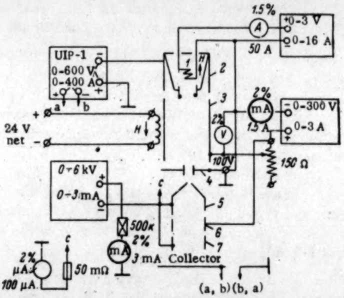

Fig. 4. Block diagram of the power supply.

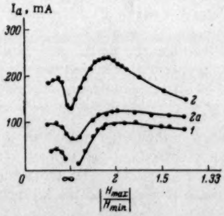

Fig. 5. Dependence of the discharge current on the external magnetic field. 1) Conventional ion source I_{heater} = 16 A, V_a = 25 V; 2) proposed ion source, free operation of the cathode, I_{heater} = 16 A, V_a = 50 V; 3) proposed ion source, cathode operated with a load, I_{heater} = 13 A, and V_a = 118 V.

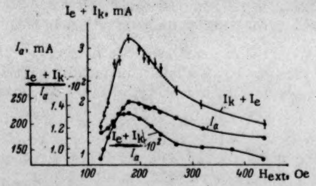

Fig. 6. Output ion current and plasma contraction as functions of the external magnetic field. $V_a = 56$ V and $V_e = 5250$ V.

portion to the increase in the external magnetic field ($H_{ext} >$ 180 Oe), the electron-optical effect decreases due to a reduction of the degree of magnetic field inhomogeneity; curve 2 approaches curve 1.

When the voltage applied to the discharge increases due to increasing cathode-voltage drops due to the load, the ratio of directed velocity to random velocities of the electrons is shifted in favor of the random velocities. This reduces the electron-optical contraction, in full agreement with Figure 5 (curve 2a).

Similarly, the external magnetic field influences the ion-output current from the source, i.e., the current $I_k + I_e$ (I_k denotes the ion current passing through the extractor to a Faraday cylinder, and I_e denotes the ion current fraction which ends on the extractor). The curve $(I_k + I_e)/I_a = f(H)$ (Fig. 6) has its maximum at 180 Oe ($H_{max}/H_{min} = 2.25$), which means that the maximum plasma contraction occurs under these conditions.

The ions are extracted from the source with a voltage of 4-5 kV. The maximum current flow seems to correspond to the crossover position in the extractor opening. At an extraction voltage of 4 kV the maximum current in the system is obtained under the following conditions in a neon atmosphere: $I_a = 180$ mA, $H_{ext} = 180$ Oe, and $V_a = 56$ V. The transmitted current is 71%, and the ion current in the beam is $I_k^+ = 1$ mA. At $V_{extr} = 5$ kV the maximum current flow is 65% and is observed at $I_a = 300$ mA, $H_{ext} = 180$ Oe, and $V_a = 56$ V. The current in the ion beam is 1.5 mA.

With this design of the extraction system (Fig. 1b), the amount of gas leaking from the discharge chamber is given by the dimensions of the opening in the extractor.

The width of the energy spectrum is given by the voltage applied to the discharge as in the case of the usual Penning ion source. The width of the energy spectrum is independent of the potential on the sample electrode and independent of the potential of the extractor, which should be checked in the modification of the extraction system considered.

The ion beam is then formed with the aid of an einzel lens with center electrode at the anode potential of the discharge chamber (Fig. 1a). The geometric parameters of the einzel lens are derived on the following basis. The length of the cylinder of the first electrode is chosen so that the crossover of the beam (object) is located outside the field of the lens. Furthermore, in order to obtain an ion beam which is parallel at the output, the focus of the ion-optical system is shifted along with the crossover of the beam (extractor opening). The aperture of the beam is determined from the retardation curve on a plane electrode situated at a distance of 10 cm from the lens. Then, the effect of the space charge is taken into account. Good parallelism of the ion current behind the lens is established, i.e., the ion-optical system works in a manner close to that calculated.

Our source is operated in a neon atmosphere or in a copper vapor atmosphere. In the latter case, the discharge is initiated in neon and afterwards transferred into a copper-vapor atmosphere by ion sputtering of the copper sample. The addition of neon to the discharge is then stopped. One must bear in mind that difficulties can be encountered when a metal sample is sputtered under the conditions existing in the discharge chamber of the ion source. For example, when the sample is irradiated with a flux of ions of an inert gas (energy of the ions about 600 eV), the sample is coated with a film which is hard to remove by sputtering. At low temperatures, this film is a polymer film which develops in the interaction of the ion current and the vapors of the diffusion-pump oil adsorbed on the sample surface. At high temperatures (up to the melting point of the sample), the film consists of metal. These films are formed on the substrate when the substrate surface is irradiated with ions of an inert gas, provided that metal vapors are present in the chamber even at low partial pressures $p \geq 10^{-9}$ torr.

The copper sample is sputtered in the following manner. First, the discharge is ignited in neon ($I_a = 280$ mA and $V_a = 56$ V). Copper ring 3 ($V_{ring} = -500$ V) is heated by ion bombardment to a temperature at which an intensive evaporation takes place. The supply of neon is thereafter interrupted. The discharge current increases to $I_a = 500$ mA at $V_a = 20$ V and the discharge continues to burn in copper vapors. The cathode sputtering of the cylindrical copper sample around the anode is initiated by applying a negative voltage. Ring 3 rapidly evaporates and cathode sputtering of the sample (self-sputtering) is the only mechanism maintaining the atmosphere of copper vapors in the discharge chamber. A copper-ion current of 1.5 mA is obtained at $I_a = 500$ mA, $H_{ext} = 180$ Oe, and $V_{extr} = 4$ kV.

Ions of various metals can be obtained in this fashion. The thermal conditions in the discharge chamber must evidently be controlled in certain cases. When copper ions are generated, the plasma chamber is operated with no constraints, i.e., it is not heated or cooled.

(Submitted February 19, 1973)
Zh. Tekh. Fiz., 44, 429-434 (February 1974)

The possibility solving the inverse problem for scattering of coherent radiation in moving media is discussed. Equations are obtained that relate the spectral dependence of fluctuations in the intensity of scattered radiation to the velocity and size distributions of the particles. The problem is easily inverted for scattering in laminar flow when an external field acts on the particles. Experimental results are presented.

The problem of a noncontact measurement of the characteristics of dispersed media is important in science and engineering. In the present paper we investigate the optical field of scattered radiation in moving media and use the results to develop a method of measuring the size and velocity distributions of particles in the dispersed material. The essence of the method is measurement of the Doppler-frequency spectrum of the optical field $S(\omega)$ resulting from scattering by the moving particles. If the particle sizes ρ and speeds v are connected by a simple analytical relationship, the particle size distribution $n(\rho)$ and speed distribution $n(\mathbf{v})$ can be recovered from $S(\omega)$. Conditions favorable for the application of this method can be created artificially in certain cases and often occur naturally in actual flow of a liquid or a gas. For example, a simple relationship between particle size and velocity holds for steady fall of particles in a liquid or gaseous medium, in the settling of particles from a laminar flow under the action of gravity, and in the motion of charged particles in an electric field. A more complex situation occurs in a turbulent flow (see ref. 2). We have conducted detailed investigations of cases of scattering of radiation by particles moving in a laminar flow of liquid or gas, and fall in a medium at rest.

1. THE SPECTRAL FUNCTION $S(\omega)$

The calculation of the spectral function $S(\omega)$ for the fluctuations in the intensity of radiation experiencing single scattering in a volume V and combined with a reference signal, as is usual when investigating a Doppler frequency spectrum, is carried out under the following assumptions.

a) The field of nonuniformities in the scattering volume V is stationary and homogeneous. The particles do not leave the photometric volume V during the time required to correlate the intensity fluctuations at the observation point, and the particle velocities do not change.

b) The density of the scattering particles is small, i.e., the particles are not interacting with each other.

c) Multiple scattering does not occur.

d) The scattered and reference signals are coherent.

The photodetecting surface is much smaller than the coherence area of the scattered radiation, and the angle between the fronts of the scattered and reference radiation is small.

The intensity of the total optical field of the scattered radiation and the reference beam at time t is[2]

$$\begin{aligned} I(t) = |E(t)|^2 = a_0^2 + \sum_i a_i^2 \Theta_i(t) \\ + 2a_0 \sum_i a_i \Theta_i(t) \cos\{\varphi + \varphi_i + \mathbf{k}\mathbf{r}_i(t)\} \\ + \sum_{i \neq j}\sum a_i a_j \Theta_i(t)\,\Theta_j(t) \exp[i\mathbf{k}\{\mathbf{r}_i(t) - \mathbf{r}_j(t)\} + i(\varphi_i - \varphi_j)], \end{aligned} \tag{1}$$

where $\Theta_i(t) = I$ if the i-th particle is in the volume, and 0 if the i-th particle is not in the volume; a_0, φ_0 are the amplitude and phase of the field of reference radiation; a_i, φ_i are the amplitude and phase of the scattered radiation; $\mathbf{r}_i(t)$ is the radius vector of the location of the i-th scattering particle; and $\mathbf{k} = \mathbf{k}_s - \mathbf{k}_0$; $\mathbf{k}_0$, $\mathbf{k}_s$ are the wave number vectors of the incident and scattered radiation.

In contrast to ref. 2 we consider the case in which the motion of the scattering particle depends on its parameters.

Then the expression for the autocorrelation function will have the form

$$\begin{aligned} K(\tau) = \langle I(t)\, I(t+\tau)\rangle - \langle I(t)\rangle^2 \\ = [\overline{a_i^4} - (\overline{a_i^2})^2]\langle N\rangle + (\overline{a_i^2})^2(\langle N^2\rangle - \langle N\rangle^2) + 2a_0^2 \langle \sum_i a_i^2 \Theta_i(t) \cos[\mathbf{k}\Delta\mathbf{r}]\rangle \\ + \langle \sum_m \sum_n a_m^2 a_n^2 \Theta_m(t)\,\Theta_n(t) \exp i\mathbf{k}(\Delta\mathbf{r}_m - \Delta\mathbf{r}_n)\rangle - \overline{a_i^4}\langle N\rangle. \end{aligned} \tag{2}$$

The bar denotes averaging over the particles in the volume V, and the brackets denote averaging over the observation time $T \gg \tau$. According to assumption a) the probability of displacement of the i-th particle by $\Delta\mathbf{r}$ in time τ is

$$P(\Delta\mathbf{r}_i \mid \tau) = \delta(\Delta\mathbf{r}_i - \mathbf{v}_i\tau), \tag{3}$$

where $\mathbf{v}_i$ is the velocity of the i-th particle.

We assume that the scattering particles are spherical, so that $a_i^2 = a_i^2(\rho_i, \mathbf{k})$, where ρ_i is the radius of the i-th particle. We denote the multivariate distribution of the probabilities $v_i^k = \mathbf{v}_i(\mathbf{k}/k)$. Substituting Eq. (3) into Eq. (2), we obtain

$$\begin{aligned} K(\tau) = [\overline{a_i^4} - (\overline{a_i^2})^2]\langle N\rangle + (\overline{a_i^2})^2(\langle N^2\rangle - \langle N^2\rangle) \\ + 2a_0^2\langle N\rangle \int_{-\infty}^{\infty} P(v^k, \rho)\, a^2(\rho, \mathbf{k}) \cos[\mathbf{k}\mathbf{v}\tau]\, dv^k d\rho \\ + \langle N\rangle^2 \iint_{-\infty}^{\infty} P(v_m^k \rho_m v_n^k \rho_n)\, a_m^2 a_n^2 \\ \times \exp\{i\mathbf{k}(\mathbf{v}_m - \mathbf{v}_n)\tau\}\, dv_m^k dv_n^k d\rho_m d\rho_n - \overline{a_i^4}\langle N\rangle. \end{aligned} \tag{4}$$

The spectral function for the fluctuations of intensity of scattered radiation is

$$S(\omega)=\frac{1}{2\pi}\int_{-\infty}^{\infty}e^{i\omega\tau}K(\tau)\,d\tau=[\overline{a_i^4}-(\overline{a_i^2})^2]\langle N\rangle$$

$$+(\overline{a_i^2})[\langle N^2\rangle-\langle N\rangle^2]\delta(\omega)$$

$$+\iiiint n(v_m^k\rho_m v_n^k\rho_n)\,a_m^2a_n^2\delta[\omega-(v_m^k-v_n^k)]\,dv_m^k dv_n^k d\rho_m d\rho_n$$

$$-\overline{a_i^4}\langle N\rangle\delta(\omega)]$$

$$+a_0^2\int\int_{-\infty}^{\infty}n(v^k,\ \rho)\,a^2(\rho,\ \mathbf{k})[\delta(\omega-\mathbf{kv})+\delta(\omega+\mathbf{kv})]\,dv^k d\rho. \qquad (5)$$

The first group of terms on the right side of Eq. (5) results from fluctuations of intensity of radiation scattered by individual particles, and from fluctuations in the number of particles in volume V. The second term describes the Doppler frequency shift for the radiation scattered by two particles moving with relative velocity $\mathbf{v}_{mn} = \mathbf{v}_m - \mathbf{v}_n$. The third term gives the Doppler frequency shift for scattering by a particle moving with velocity $\mathbf{v}$ in the laboratory coordinate system. If the intensity of scattered radiation is much less than that of the reference signal, the spectral function becomes

$$S(\omega)=\frac{a_0^2}{k}\left[\int_{-\infty}^{\infty}a^2(\rho,\ \mathbf{k})\,n(v_1^k,\ \rho)\,d\rho+\int_{-\infty}^{\infty}a^2(\rho,\ \mathbf{k})\,n(v_2^k,\ \rho)\,d\rho\right], \qquad (6)$$

where $v_1^k = \omega/k$, $v_2^k = -\omega/k$.

In almost all cases the velocity vectors for all the scattering particles lie within a cone with apex angle $\gamma < \pi$. Therefore we can choose the vector **k** to satisfy one of the following conditions:

$$\left.\begin{array}{l}1)\ n(v_i^k,\ \rho)=0\ \text{for}\ \mathbf{kv}_i<0\\ \text{or}\ 2)\ n(v_i^k,\ \rho)=0\ \text{for}\ \mathbf{kv}_i>0.\end{array}\right\} \qquad (7)$$

Then only one term remains in Eq. (6). Since

$$P(v^k,\ \rho)=P(v^k)\,P(\rho\,|\,v^k)=P(\rho)\,P(v^k\,|\,\rho), \qquad (8)$$

we obtain the following equation for the particle size distribution function:

$$S[|kv^k|]=\frac{a_0^2}{k_0^2}\frac{BdQd\Omega}{k\Delta S}V\int\mu(\rho,\ \mathbf{k})\,n(\rho)\,P(v^k\,|\,\rho)\,d\rho, \qquad (9)$$

where B and dQ are the brightness and the solid angle of the radiation incident on the photometric volume V; $\Delta\Omega$ and ΔS are the reception angle and the working area of the photocathode, normal to the incident radiation; $\mu(\rho, \mathbf{k})$ is the scattering index normalized in the usual way, $(1/k_0^2)\cdot\int\mu(\rho, \mathbf{k})\,d\omega = \alpha$ (α is the particle scattering cross section); and a_0^2 is the reference radiation intensity.

It follows from Eq. (9) that the contribution to the spectral function at frequency ω is from radiation scattered by particles with velocity a_0^2.

Making use of Eqs. (7) and (8), we can also write Eq. (6) in the form

$$S(|kv^k|)=\frac{a_0^2}{k_0^2}\frac{BdQ\Delta\Omega}{\Delta Sk}Vn(v^k)\int\mu(\rho,\ \mathbf{k})\,P(\rho\,|\,v^k)\,d\rho. \qquad (10)$$

Equations (9) and (10) are equations for the functions $n(\rho)$ and $n(v^k)$, and can be solved if the experimental conditions allow determination of the functions $P(v^k/\rho)$ and $P(\rho/v^k)$.

Relations (9) and (10) are greatly simplified if there is a unique relation between ρ and v^k.

We assume that there is scattering of coherent radiation by particles moving in a laminar stream with velocity $\mathbf{v}_i = \mathbf{v}_0 + \mathbf{W}_i$, where $\mathbf{v}_0$ is the velocity of the medium, $\mathbf{W}_i$ is the relative velocity of the i-th particle, σ_0 = const is the medium density, and σ_i = const is the particle density. Gravity acts on the particles in addition to the hydrodynamic forces. In the region of applicability of the Stokes equation[2] we have

$$\mathbf{W}_i=\frac{2}{9}\frac{\Delta\sigma}{\eta}\rho_i^2\mathbf{g}. \qquad (11)$$

Here $\Delta\sigma = \sigma_i - \sigma_0$, η is the viscosity of the medium, and $\mathbf{g}$ is the gravitational acceleration.

Relations (9) and (10) take the following simple form:

$$n(v^k)=\frac{\Delta Sk_0^2kS\,[|kv^k|]}{a_0^2BdQ\Delta\Omega V\mu\left[\mathbf{k},\ \rho=\sqrt{\frac{9}{2}\eta\frac{(v^k-v_0^k)}{\Delta\sigma g}}\right]}, \qquad (12)$$

$$n(\rho)=\frac{4}{9}\frac{k_0^2\Delta Sk}{a_0^2BdQ\Delta\Omega V}\frac{\Delta\sigma g^k\rho}{\mu(\mathbf{k},\ \rho)}S\left[\left|\mathbf{k}\left(\mathbf{v}_0+\frac{2}{9}\frac{\Delta\sigma}{\eta}\rho^2\mathbf{g}\right)\right|\right]. \qquad (13)$$

Relations (12) and (13) allow us to determine $n(v^k)$ and $n(\rho)$ from the experimentally obtained function $S(\omega)$. The frequency spectrum is usually measured in relative units. To determine $n(v^k)$ or $n(\rho)$ in absolute units it is sufficient, for example, to measure the transmission for radiation propagating straight through the photometric volume.

We note that the problem of calculating $n(v^k)$ and $n(\rho)$ is correctly posed in the case considered, in distinction from other problems of this kind, e.g., the small angle method (ref. 3) and the spectral transparency method (ref. 4).

We now determine the limits of applicability of this method. 1. As formulated above the method is suitable only for laminar flows in the region of application of the Stokes equation (refs. 1, 5).

2. The limit of resolution of two close fractions is given by the resolution of the spectral analyzer and can be calculated from the inequality

$$\frac{\Delta f}{f}<\frac{\Delta\omega}{\omega}=\frac{\mathbf{k}(\mathbf{v}_2-\mathbf{v}_1)}{\mathbf{k}\left(\mathbf{v}_0+\frac{\mathbf{w}_1+\mathbf{w}_2}{2}\right)}=\frac{\frac{4}{9}\frac{\Delta\rho\sigma_0}{\eta}\mathbf{kg}}{\mathbf{k}\left(\mathbf{v}_0+\frac{2}{9}\frac{\Delta\sigma\rho}{\eta}(\rho_1^2+\rho_2^2)\,\mathbf{g}\right)}, \qquad (14)$$

where $\Delta f/f$ is the relative resolution of the spectral instrument, $\rho_0 = (\rho_1 + \rho_2)/2$, and $\Delta\rho = \rho_2 - \rho_1$.

2. EXPERIMENT

The method described above has been used to measure the sizes of scattering particles passing through the photometric volume at different times in precipitation

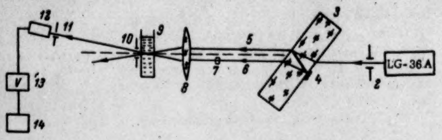

Fig. 1. Experimental arrangement. 1) LG-36A gas laser; 2, 10, 11) diaphragms; 3) plane-parallel slab; 4) reflecting coating; 5,. 6) primary and reference rays; 7) neutral filter; 8) lens; 9) medium; 12) type FÉU-79 photomultiplier; 13) amplifier; 14) FSP-80 spectral analyzer.

of the particles in a fluid at rest ($v_0 = 0$). The experimental conditions satisfy all the conditions enumerated in Sec. 1. The experimental arrangement is illustrated in Fig. 1. A special feature is the method for forming the reference signal, which is obtained by double reflection of the incident radiation from the plane-parallel slab 3, which has a small optical wedge angle. In this case the primary and reference rays are parallel. The rays are focused by the single lens 8. This optical system gives very simple compliance with the condition (c) of Part 1. Adjustment of the system simply means locating the medium at the focus of lens 8. An FSP-80 spectral analyzer is used to perform parallel analysis of the random signal with the aid of 38 filters spanning the range 2 Hz to 20 kHz.

A thin cell 9, filled with distilled water, is positioned at the focus of lens 8. The scattering particles are introduced into the cell in small samples. To determine the effect on the measured results of perturbation of the medium upon the addition of the scattering particles, of oscillations of the fluid and of convective motion (i.e., the instrumental background), we perform an experiment with latex particles ($\rho = 0.09\ \mu$, $\Delta\sigma = 0.06\ \text{g/cm}^3$), which in fact follow the motion of the medium completely. Figure 2a shows the spectral function for the latex particles. The spectral broadening due to Brownian motion for the given experimental geometry is $\Delta f < 1$ Hz (ref. 6), which is much less than the bandwidth of the analyzer filters, and introduces essentially no distortion into the shape of the function $S(f)$ under investigation.

The test specimens we use are particles of corundum ($\Delta\sigma = 3\ \text{g/cm}^3$) and glass ($\Delta\sigma = 1.5\ \text{g/cm}^3$). The size distribution is shown in Fig. 3. At the top of the figure is the frequency scale corresponding to a specific particle radius. Because of their different rates of fall, some time after the particles are introduced into the medium we see a vertical particle size stratification, which changes with time. Therefore, particles ranging from coarse to very fine traverse the photometric volume and the maximum in the measured spectral function is displaced towards low frequency (Fig. 4). The experimentally obtained range of variation of frequency f (Fig. 4) agrees with that calculated (Fig. 3). During the experiment data obtained from measurements of $S(f)$ are compared with results of measurements under the microscope of samples taken from the scattering volume immediately following measurement of $S(f)$. The results coincide within a tolerance given by the transmission bandwidth of the analyzer filters.

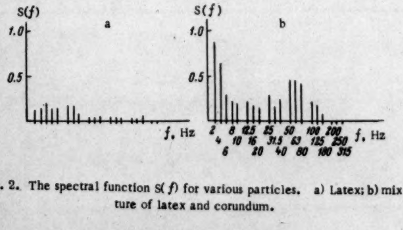

Fig. 2. The spectral function $S(f)$ for various particles. a) Latex; b) mixture of latex and corundum.

The sensitivity of this method is a matter of practical interest. Figure 2b shows the spectral function $S(f)$ for the case of a two-component disperse medium, consisting of a combination of particles of latex and corundum. The intensity of the radiation scattered by the latex is approximately an order of magnitude greater than that from the corundum, but the appearance of the corundum particles in the volume V is easily recorded.

Thus, when applicable, this method enables one to establish the particle velocity and size distribution functions. It is simple, both from the viewpoint of technical implementation and as regards mathematical reduction of the results of direct measurement. It is especially useful for recording the appearance in the scattering volume of particles which differ in density or size from particles previously occupying the volume.

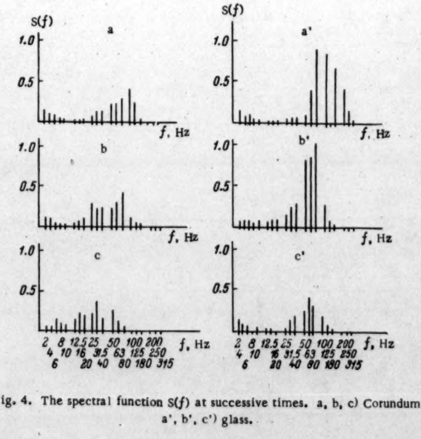

Fig. 4. The spectral function $S(f)$ at successive times. a, b, c) Corundum; a', b', c') glass.

The method described allows analysis of the microstructure and the velocity field of a dispersed phase with good time and space resolution, and, when allied with the cross-correlation method of ref. 7, allows measurement of the parameters of large-scale nonuniformities, thus providing a large volume of information concerning processes occurring in streams of liquid or gas.

Condensation of a dense vapor flow

V. G. Dneprovskii, B. A. Osadin, and N. V. Rusakov

(Submitted December 12, 1972; resubmitted April 12, 1973)
Zh. Tekh. Fiz., 44, 435-441 (February 1974)

The distinctive features of the conditions prevailing during the condensation of a dense vapor flow produced in pulsed evaporation by means of highly intense heat sources (lasers, exploding wires, and plasma guns) are analyzed. Equations describing the nonequilibrium layer immediately adjacent to the condensation surface are derived for the case in which some of the molecules are elastically reflected from the condensation surface and for the case of diffuse reflection. It is shown that, in contrast with the conditions for condensation in free-molecular vapor flow, the properties of this nonequilibrium layer in this case are strong functions of the condensation coefficient. For example, in the case of elastic reflection with a condensation coefficient $\alpha \leq 0.85$ the condensation occurs from a flow which has been nearly stopped. The conditions under which the derived equations are applicable are discussed. It is shown that they can be used to solve transient problems.

There are a number of recent papers which deal with the use of intense heat sources (lasers, exploding wires, and plasma guns) to produce thin films.[1–4] The vapor (or plasma) flow toward the condensation surface (a substrate or wall) in experiments of this type is distinguished by high velocities (frequently much higher than the thermal velocities) and high densities, so that such a flow is usually treated as a gas-dynamic flow, in contrast with the free-molecular flows which were previously used to deposit thin films in vacuum.[5]

Under molecular-flow conditions, with the mean free path larger than the distance from the evaporator to the substrate, the circumstance that the condensation coefficient is not equal to unity has essentially no influence on the condensation process. For a dense flow, on the other hand, this circumstance should, in general, change the flow conditions (the external problem) and change the condensation conditions and the temperature field in the condensation device (the internal problem).

A distinctive feature of the external problem of the condensation of a dense vapor flow is that it is necessary to analyze the nonequilibrium vapor sheath immediately adjacent to the substrate. This sheath results from both evaporation and the circumstance that the condensation coefficient is different from unity.

In this work we analyze the conditions prevailing near the surface at which a dense vapor flow condenses.

We assume that a vapor flow is incident from the left on a vertical substrate. The vapor is a monatomic ideal gas having the following properties at infinity, i.e., at the outlet from the evaporator: density n_∞, temperature T_∞ (mass density ρ_∞ and pressure p_∞), and flow velocity v_∞. We assume that at infinity the flow has an equilibrium distribution function in the coordinate system fixed in the flow:

$$f_\infty = n_\infty \left(\frac{m}{2\pi k T_\infty}\right)^{3/2} \exp\left\{-\frac{m}{2kT_\infty}\left[(v_x+v_\infty)^2+v_y^2+v_z^2\right]\right\}. \quad (1)$$

The x axis is directed toward the oncoming flow, and v_∞ is the magnitude of the flow velocity.

In a nonequilibrium sheath with thickness of the order of the mean free path at the wall, there are two oppositely directed flows; the distribution function at the wall is then written as the sum

$$f_0 = f_- + f_+, \quad (2)$$

where f_- describes the particles incident on the wall ($v_x \leq 0$) and f_+ describes the reflected particles ($v_x \geq 0$). The actual forms of f_- and f_+ are functions of the conditions prevailing at the condensation surface (elastic reflection of atoms which have not condensed, diffuse reflection, reevaporation, etc.). If these functions are specified, e.g., Maxwellian distributions, the problem which remains is simply one of determining the parameters of these distributions.

A similar approach to the kinetics of the nonequilibrium sheath which arises during evaporation in vacuum has been developed by Romanov and Pustovalov.[6] In the case of evaporation the use of the distribution function at infinity as given in (1) requires certain additional reservations,[7] while in our case condition (1) is simply a specified condition.

We treat the steady-state problem, i.e., we first assume that the temperature of the condensation surface does not change during condensation and that reevaporation does not occur. Second, we assume that the transient gas-dynamic pressure which arises as the oncoming flow collides with the wall has decayed and produced a steady-state flow. The criterion for the absence of reevaporation is given below. With regard to the assumption of a gas-dynamic steady-state, we note that, e.g., under the experimental conditions of ref. 4, the transient flow pattern is observed for only a few microseconds, so that even when the condensation continues for only tens of microseconds the assumption of a steady-state is in accordance with the actual nature of the process.

CONDITIONS AT THE WALL FOR ELASTIC REFLECTION

In the case in which some of the particles are elastically reflected we can approximate f_- as an equilibrium function (n_0, T_0, v_0) with a clipped positive tail, and we can approximate f_+ as the mirror-reflected distribution with ordinates smaller than those of f. In other words,

$$f_- = a_- \exp\left\{-\frac{m}{2kT_0}\left[(v_x+v_0)^2+v_y^2+v_z^2\right]\right\}, \quad v_x \leqslant 0, \quad (3)$$

$$f_+ = a_+ \exp\left\{-\frac{m}{2kT_0}\left[(v_x-v_0)^2+v_y^2+v_z^2\right]\right\}, \quad v_x \geqslant 0, \quad (4)$$

where v_0 is the magnitude of the "velocity" of the forward and reverse flows.

Normalizing f_0 to the particle density at the wall, n_0, and using the condition for the elastic reflection of uncondensed particles in one of the three equivalent forms

$$\left.\begin{aligned} M&=M_-+M_+=\alpha M_-,\\ P&=P_-+P_+=(2-\alpha)P_-,\\ W&=W_-+W_+=\alpha W_-, \end{aligned}\right\} \tag{5}$$

we find the following equations for the normalization factors:

$$a_-=\frac{2}{2-\alpha}\frac{n_0}{(\sqrt{\pi}v_{T0})^3[1+\operatorname{erf}(z)]}, \tag{6}$$

$$a_+=\frac{2(1-\alpha)}{2-\alpha}\frac{n_0}{(\sqrt{\pi}v_{T0})^3[1+\operatorname{erf}(z)]}. \tag{7}$$

In (5), M₋, P₋, and W₋ are the mass, momentum, and energy fluxes associated with distribution function f_- (toward the substrate); M₊, P₊, and W₊ are the mass, momentum, and energy fluxes associated with distribution function f_+ (from the substrate); and M, P, and W are the resultant fluxes to the substrate. Explicitly,

$$\left.\begin{aligned} M_-&=\int_{-\infty}^{0}\int_{-\infty}^{\infty}\int_{-\infty}^{\infty} f_- m v_x^2\,dv_x\,dv_y\,dv_z,\\ P_-&=\int_{-\infty}^{0}\int_{-\infty}^{\infty}\int_{-\infty}^{\infty} f_- m v_x^2\,dv_x\,dv_y\,dv_z,\\ W_-&=\int_{-\infty}^{0}\int_{-\infty}^{\infty}\int_{-\infty}^{\infty} f_- \frac{m}{2}(v_x^2+v_y^2+v_z^2)\,v_x\,dv_x\,dv_y\,dv_z. \end{aligned}\right\} \tag{8}$$

In Eqs. (6) and (7) we have used

$$v_{T0}=\sqrt{\frac{2kT_0}{m}},\quad z=\frac{v_0}{v_{T_0}},\quad \operatorname{erf}(z)=\frac{2}{\sqrt{\pi}}\int_0^z \exp(-\xi^2)\,d\xi.$$

In the steady-state the values of M, P, and W are constant along the flow so that, with absolute values in mind, we can write these quantities as

$$\left.\begin{aligned} M&=mn_\infty v_\infty=\rho_\infty v_\infty,\\ P&=n_\infty kT_\infty+mn_\infty v_\infty^2=p_\infty+\rho_\infty v_\infty^2,\\ W&=\frac{5}{2}n_\infty kT_\infty v_\infty+\frac{m}{2}n_\infty v_\infty^3=\rho_\infty v_\infty\left(\frac{5}{2}\frac{p_\infty}{\rho_\infty}+\frac{v_\infty^2}{2}\right), \end{aligned}\right\} \tag{9}$$

i.e., equate the corresponding gas-dynamic fluxes.[8,9] On the other hand, calculating the kinetic moments in (8), we find

$$\left.\begin{aligned} &M=\frac{\alpha}{2-\alpha}n_0 m v_0 f_M(z);\quad f_M(z)=z+\frac{1}{\sqrt{\pi}}\frac{\exp(-z^2)}{1+\operatorname{erf}(z)};\\ &P=n_0 m v_{T0}^2 f_P(z);\quad f_P(z)=z^2+\frac{1}{2}+\frac{1}{\sqrt{\pi}}\frac{z\exp(-z^2)}{1+\operatorname{erf}(z)};\\ &W=\frac{\alpha}{2-\alpha}n_0\frac{m}{2}v_{T0}^3 f_W(z);\\ &f_W(z)=z^3+\frac{5}{2}z+\frac{1}{\sqrt{\pi}}\frac{(z^2+2)\exp(-z^2)}{1+\operatorname{erf}(z)}. \end{aligned}\right\} \tag{10}$$

By solving system (10) we can determine the properties n₀, T₀, v₀ of the nonequilibrium sheath, which are to be understood as the parameters of the nonequilibrium distribution function at the wall, f_0, for the specified gas-dynamic fluxes at the outlet from the evaporator (M, P, W) and for the specified condensation coefficient α. From (10) we find an equation for z:

$$F(z)=\frac{f_M f_W}{f_P^2}=2\left(\frac{2-\alpha}{\alpha}\right)^2\frac{MW}{P^2}. \tag{11}$$

Here, F(z) is a monotonically decreasing function, which tends toward unity as z → ∞ (Fig. 1). In this connection, the specification of M, P, and W means that not all possible values of α are allowed, but only those for which

$$1\geqslant\alpha\geqslant\alpha_{\min}=\frac{2}{1+\sqrt{\frac{P^2}{2MW}F(0)}}. \tag{12}$$

It is easy to see the physical meaning of this result: With $\alpha<\alpha_{\min}$ the inverse effect of the substrate on the evaporator becomes so strong that it changes the fluxes M, P, and W; the perturbation of the flow which results from the collision with the wall is propagated back to the evaporator.

CONDITIONS AT THE WALL FOR DIFFUSE REFLECTION

We again assume that the reverse particle flow arises only because α is different from unity, but we assume that the velocity distribution of the reflected particles is governed by the surface temperature T_n, which is assumed low ($T_n \ll T_0$) and relatively constant during the condensation. In other words, we write the distribution function at the wall in form (2) where

$$f_-=a_-\exp\left\{-\frac{m}{2kT_0}[(v_x+v_0)^2+v_y^2+v_z^2]\right\},\quad v_x\leqslant 0, \tag{13}$$

$$f_+=a_+\exp\left\{-\frac{m}{2kT_n}(v_x^2+v_y^2+v_z^2)\right\},\quad v_x\geqslant 0. \tag{14}$$

As before, normalizing f_0 to n₀ and using the same mass-reflection condition, we find

$$a_-=\frac{2n_0}{(\sqrt{\pi}v_{T0})^3}\frac{1}{[1+\operatorname{erf}(z)][1+\sqrt{\pi}(1-\alpha)yz]+(1-\alpha)y\exp(-z^2)}, \tag{15}$$

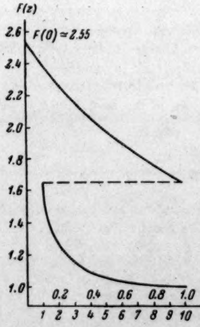

Fig. 1

$$a_+ = \frac{2(1-\alpha)n_0}{(\sqrt{\pi}v_{T0})^3}\frac{\sqrt{\pi}\,z\,[1+\mathrm{erf}(z)] + \exp(-z^2)}{[1+\mathrm{erf}(z)][1+\sqrt{\pi}(1-\alpha)yz] + (1-\alpha)y\exp(-z^2)}y^4, \tag{16}$$

where $y = v_{T0}/v_{Tn}$, $v_{Tn} = (2kT_n/m)^{1/2}$.

We again write

$$M = M_- + M_+ = \alpha M^- \tag{17}$$

and assume since T_n is low that

$$P = P_-,\quad W = W_-. \tag{18}$$

Then after calculating the kinetic moments in (8) we find

$$\left.\begin{aligned} M &= \alpha n_0 m v_{T0}\frac{f_M(z)}{f(y,z)},\\ P &= n_0 m v_{T0}^2\frac{f_P(z)}{f(y,z)},\\ W &= n_0\frac{m}{2}v_{T0}^3\frac{f_W(z)}{f(y,z)}, \end{aligned}\right\} \tag{19}$$

where f_M, f_P, and f_W are again given by Eqs. (10); M, P, and W are given by Eqs. (9); and

$$f(y,z) = 1 + \sqrt{\pi}(1-\alpha)yz + (1-\alpha)y\frac{\exp(-z^2)}{1+\mathrm{erf}(z)}. \tag{20}$$

By solving system (19) we can determine the properties of the nonequilibrium sheath, n_0, T_0, and v_0, which are to be understood as the parameters of the nonequilibrium distribution function at the wall, f_0, for the specified gas-dynamic fluxes at the outlet from the evaporator (M, P, and W), the condensation coefficient α, and the temperature of the condensation surface, T_n. From (19) we find an equation for F(z):

$$F(z) = \frac{f_M f_W}{f_P^2} = \frac{2}{\alpha}\frac{MW}{P^2}. \tag{21}$$

From this equation we find, for specified values of M, P, and W,

$$1 \geqslant \alpha \geqslant \alpha_{\min} = \frac{2MW}{P^2}\frac{1}{F(0)}. \tag{22}$$

Equation (22) predicts smaller "allowed" values of the condensation coefficient than does Eq. (12), in accordance with the lesser effect of the substrate on the evaporator in the case of diffuse reflection.

We now turn to a numerical example. We assume that the parameters of the flow at the outlet from the evaporator are $n_\infty = 10^{16}$ cm^{-3}, $T_\infty = 5 \cdot 10^3$ °K, and $v_\infty = 5 \cdot 10^5$ cm/sec. We assume that the vapor is a monatomic ideal gas with an atomic weight $\mu = 32$ (the atomic weight of sulfur), and we assume that the substrate surface is at $T_n = 500$°K. Table 1 shows the characteristics of the nonequilibrium sheath: the conditions at the wall for the case of elastic reflection (the upper two rows) and for the case of diffuse reflection (the remaining rows). It follows from this table that if the condensation coefficient is even slightly different from unity in the case of elastic reflection there will be a significant slowing of the flow in front of the wall (with $\alpha = 0.85$ the condensation occurs from a flow which has been slowed essentially completely). In the case of diffuse reflection the flow is slowed less (and smaller values α are "allowed"), but there is a much higher density in the nonequilibrium sheath.

TABLE 1

α	z	$n_0 \cdot 10^{-16}$, cm^{-3}	$T_0 \cdot 10^{-3}$, °K	$v_0 \cdot 10^{-5}$, cm/sec
0.90	0.90	1.90	18.6	2.80
0.85	0.42	2.52	24.6	1.50
0.90	2.00	3.24	8.9	4.28
0.80	1.50	6.12	10.4	3.46
0.70	1.01	9.95	12.4	2.53
0.50	0.22	23.0	14.0	0.68

This example is obviously purely illustrative since we have neglected the actual state of the material.

CONDITION FOR NO REEVAPORATION

The inverse evaporation from the substrate is governed by the temperature of the surface on which the condensation occurs. In the moving coordinate system ($x' = x + v_k t$) when the condensation occurs on a homogeneous substrate (the thermal constants of the substrate and the condensate are the same), the heat-conduction problem can be written

$$\left.\begin{aligned} &\frac{\partial T}{\partial t} = a^2\frac{\partial^2 T}{\partial x'^2} - v_k\frac{\partial T}{\partial x'},\quad x' \geqslant 0,\\ &\left.\frac{\partial T}{\partial x'}\right|_{x'=0} = -\frac{Q}{k},\quad T(x',0) = T_0, \end{aligned}\right\} \tag{23}$$

where $v_k = M/\gamma$ is the condensation rate, $Q = W + (\lambda - c_p T)$ is the heat flux, λ is the heat of evaporation, c_p is the specific heat of the condensate at constant pressure, k is the thermal conducitivity, a^2 is the thermal diffusivity, T_0 is the initial substrate temperature, and the x axis is directed into the substrate. Neglecting the enthalpy of the condensate in comparison with W, we can simplify the boundary condition in (23) ($Q = W + \lambda M$), and using the method of integral transforms we can find the following solution for this problem:[9]

$$T(x',t) = T_0 + \frac{aQ}{k}\exp\left(\frac{v_k}{2a^2}x'\right)\int_0^t\left\{\frac{1}{\sqrt{\pi\tau}}\exp\left[-\left(\frac{v_k^2}{4a^2}\tau + \frac{x'^2}{4a^2\tau}\right)\right] + \frac{v_k}{2a}\exp\left(-\frac{v_k}{2a^2}x'\right)\mathrm{erfc}\left(\frac{x'}{2a\sqrt{\tau}} - \frac{v_k}{2a}\sqrt{\tau}\right)\right\}d\tau, \tag{24}$$

where erfc(z) = 1 − erf(z). We then find the surface temperature to be

$$T(0,t) = T_0 + \frac{aQ}{k}\int_0^t\left[\frac{1}{\sqrt{\pi\tau}}\exp\left(-\frac{v_k^2}{4a^2}\tau\right) + \frac{v_k}{2a}\mathrm{erfc}\left(-\frac{v_k}{2a}\sqrt{\tau}\right)\right]d\tau. \tag{25}$$

Introducing the unit of time $t^* = 4a^2/v_k^2$ and the unit of temperature $T^* = aQ\sqrt{t^*}/\sqrt{\pi}k)$, we can rewrite (25) as

$$u = \int_0^\theta\left[\frac{\exp(-\xi)}{\sqrt{\xi}} + \sqrt{\pi}\,\mathrm{erfc}(-\sqrt{\xi})\right]d\xi, \tag{26}$$

where

$$u = \frac{T - T_0}{T^*}\ \text{and}\ \theta = \frac{t}{t^*}.$$

For $\theta \ll 1$, the condition which corresponds physically to the initial stage of the process or to a condensation rate which is small in comparison with the velocity at which the thermal wave moves into the substrate, we can rewrite (26) as

$$u = 2\sqrt{\theta} + \sqrt{\pi}\theta, \qquad (27)$$

which differs only by the second term from the familiar solution for the case without condensation.

The condition of no evaporation can evidently be written[10]

$$M \gg \sqrt{\frac{\mu}{2\pi R T_n}}\, P(T_n), \qquad (28)$$

where R is the universal gas constant, $P(T_n)$ is the saturation vapor pressure of the given material, and $T_n \equiv T(0, t)$. With specified M and W we can use this condition to determine the maximum duration of steady-state condensation over which we can neglect reevaporation.

Numerical calculations show that for the condensation of sulfur on sulfur ($n_\infty = 10^{16}$ cm^{-3}, $T_\infty = 5 \cdot 10^5$, and $v_\infty = 5 \cdot 10^5$ cm/sec^{-1}, as before), reevaporation must be taken into account after only $t > t_p \simeq 6 \cdot 10^{-6}$ sec, while for condensation of copper on copper, with the same properties of the vapor flow, reevaporation can be neglected for a time $t = t_p \simeq 0.3$ sec.

We have analyzed the conditions prevailing at the wall in the condensation of a dense vapor flow, making significant use of the assumption of a steady-state. Turning briefly to the transient stage in the collision of the flow with the substrate, we note that the transient flow which results can be divided into two parts: a nonequilibrium kinetic part having a side on the order of the mean free path l, directly adjacent to the wall; and a gas-dynamic part (with possible rapid changes in the properties). If the characteristic time for changes in the properties in the nonequilibrium region is $\tau \sim l/v \ll t_y$, where t_y is the characteristic time for the establishment of a steady-state flow, we can use Eqs. (2)-(4) or (2), (13), and (14) above as boundary conditions for the kinetic region and use Eqs. (10) or (19) as boundary conditions for the gas-dynamic region.

In conclusion we turn to the errors associated with the approximation of the nonequilibrium distributions by a sum of Maxwellian distributions.

Obviously, any distribution with one or several clearly defined peaks can be approximated as the sum of one or more Maxwellian distributions [as was done in (2)], whose most probable velocities coincide with the peaks and whose "temperatures" give the widths of these peaks. When the distributions are normalized in the same manner, the areas under the curves representing the real and approximate distributions will be equal, and the error due to the approximation can be expressed in terms of the difference between the ordinates of the two curves. For each concrete value of v_x this error can be large; the parameters of the Maxwellian distributions describe only the general features of the situation.

When there are only two peaks – a main peak corresponding to most of the particles, at equilibrium, and an additional peak giving the deviation from equilibrium – we can estimate the errors by using the kinetic equation with a relaxation term. For the problems considered here (in the steady-state, with no fields), this term is

$$v_x \frac{\partial f}{\partial x} = -\frac{f - f_e}{\tau} \qquad (29)$$

where f_e is the equilibrium distribution function and τ is the relaxation time. Finding the ratio f/f_e from (29), we can treat the quantity

$$\delta \sim \frac{\tau}{l}\left(v_x \frac{\Delta f}{f_e}\right) \qquad (30)$$

as the relative error in the determination of the parameters of the main peak. Here l represents the dimension of the nonequilibrium sheath, over which the value of $f = f(v_x)$ changes by Δf. The distribution f_e as well as τ and l are governed by the particles corresponding to the main peak.

It follows from (30) that the errors in the approximation decrease with decreasing amplitude of the auxiliary peak and with decreasing separation of this peak from the ordinate axis. For example, for the case of elastic reflection the quantity δ reduces simply to the ratio of the normalization factors a_+ and a_-, becoming equal to $\sim(1 - \alpha)$. Accordingly, at sufficiently large condensation coefficients, Eqs. (2)-(4) turn out to be a good approximation. In the case of diffuse reflection it follows from (15) and (16) that Δf increases, and the values of v_x for the additional peak decrease. The errors remain approximately the same.

Effect of focusing conditions on the morphology of surface films produced with a laser

V. G. Dneprovskii and B. A. Osadin

(Submitted December 12, 1972; resubmitted May 26, 1973)
Zh. Tekh. Fiz., 44, 442-446 (February 1974)

Experiments on the vacuum deposition of thin films by means of a neodymium-glass laser operating in the free-run mode are reported. An optimum situation, corresponding to the minimum number of macroscopic film defects (drops, breaks, and punctures), is achieved by defocusing the beam. This situation is shown to correspond to the formation of a shallow hole (whose depth h is much smaller than its transverse dimensions) at the target. For Cu and Si with a total energy of about 150 J per pulse a radiation flux density of $q_0 \sim 10^6$ W/cm² corresponds to the optimum conditions.

Many papers have recently appeared on the use of lasers to deposit thin films in vacuum.[1-12] Interest in this method stems from the several advantages of causing evaporation with laser radiation: the minimization of the contamination of the deposited films, the possibility of achieving a high vapor-deposition rate (~ 10^6 Å/sec or higher), the possibility of evaporating refractory materials, the possibility of retaining the stoichiometry of complicated substances, the possibility of working with radioactive substances, etc. On the other hand, exploitation of these advantages is seriously hindered by the inhomogeneity of the products resulting from the destruction of a material by laser radiation: In addition to the vapor phase there are drops and even solid macroscopic particles.

In this note we describe the optimum conditions for the vacuum deposition of thin films by a laser (corresponding to the minimum number of macroscopic film defects) by defocusing the laser radiation. We have studied two materials (Cu and Si).

The experiments are carried out in an evacuated chamber at a pressure of (1-2) · 10^{-5} torr. A neodymium-glass laser (PGLS-4 glass) is used in the free-running mode. The wavelength is 1.06 μ, the pulse length is 1.6-1.8 msec, and the pulse energy can be varied up to 200 J. The relative error in the measurement of the pulse energy is about 15%. The laser radiation enters the vacuum chamber through a glass window and is focused by a lens (f = 160 mm) on the ground surface of the target (the material to be evaporated). The surface plane of the target makes an angle of 45° with the beam direction. The destruction products settle on a 45 × 60 mm glass substrate held parallel to the sample surface about 30 mm away.

The flux density is changed by changing the lens–target separation; we use $l = f$, $1.025f$, $1.050f$, $1.075f$, $1.100f$, and $1.125f$. With $l = f$ the diameter of the light spot is 500 μ. The laser beam is defocused intentionally by moving the lens away from the target; otherwise, the radiation would be focused on the target as the hole is deepened. As a rule, we study thin films produced by a single laser pulse (pulse energy of 145-160 J).

EXPERIMENTAL RESULTS

At lens–target separations of $l = f$, $1.025f$, $1.050f$, and $1.075f$ we obtain Cu and Si films differing markedly in quality (i.e., in terms of the presence of macroscopic defects). With $l = 1.100f$ and $l = 1.125f$ we detect no trace of the condensate on the substrate, either by weighing or under a microscope. We also note that sulfur (whose thermal conductivity is much poorer than that of Cu or Si) flies apart in pieces when subjected to laser radiation under analogous conditions; large individual formations can be detected by the unaided eye on the substrate along the films.

Typical experimental results for Cu and Si are shown in Table 1: d, the diameter of the laser beam at the target surface in the case of normal incidence; W, the energy of the coherent radiation reaching the target; q, the energy flux density of the coherent radiation at the target surface; d_{min}, d_{max}, and h, the minimum dimensions of the hole on the target surface and the depth of the hole, respectively; Δm, the mass loss of the target per pulse; Δm_c, the mass of condensate deposited on the substrate per pulse; and σ, the total area of the film covered by macroscopic defects (drops, breaks, and punctures), in relative units ($\sigma = Nd^2$, where N is the number of defects per unit area and d is the average defect dimension).

Figure 1 shows photographs of Cu and Si films at a magnification of × 92, along with the corresponding shapes of the holes formed by the laser radiation at the target (in a cross section along d_{max}) and photographs of the holes (×8), corresponding to the most extreme defocusing used in these experiments at which film formation was detected ($l = 1.075f$).

DISCUSSION OF RESULTS

1. It follows from the photographs of the films (Fig. 1) that there is an obvious correspondence between the

film quality and the shape of the hole formed by the laser radiation in the target. Over the range of radiation flux densities used here, $q = (1\text{-}25) \cdot 10^6$ W/cm^2, an increase in q leads to a deepening of the hole and an increase in the number of macroscopic defects in the film, primarily drops. This result is simple to explain on the basis of current ideas on the mechanism for the formation of apertures by laser radiation.[13] The vapor formed at the bottom of the hole by the direct effect of the radiation condenses partially on the walls of the hole, causing them to melt; at the same time, the high pressure forces the liquid film into a gas-dynamic flow issuing from the hole. Accordingly, a deep hole operates like a directional source of destruction products, consisting largely of the liquid phase. According to estimates based on the energy balance, the relative amount of the liquid phase in the destruction products of Cu with $l = f$, $1.025f$, and $1.050f$ is at least 70–80%; for Si, because of the lower thermal conductivity, higher melting point, and higher viscosity of the liquid phase, this relative amount is slightly less.

The sputtering effect is apparently also affected by the gas absorbed and dissolved in the target material[9] and by the peak nature of the laser pulse.[14]

2. In our case the optimum lens–target separation should be assumed to be $l = l_0 = 1.075f$ (Fig. 1, Table 1). Relatively small holes ($h \ll d_{\min}$) correspond to this separation. On the basis of these measurements it is difficult to draw any reliable conclusions regarding the relative amount of liquid phase in the destruction products for the case $l = l_0$, but photographs of the holes (Fig. 1c and d) show that in the case of a shallow hole the liquid phase is not entrained by the vapor flow and simply "spatters" out of the hole, ending up on the target surface. Evidence that the vapor phase is predominant in the latter case comes from the film quality and the energy balance.

3. Accordingly, the optimum conditions (corresponding to the fewest number of macroscopic defects in the films produced by laser evaporation) in this setup are those for which the laser radiation forms a shallow hole

at the target (the depth of the hole is much less than its transverse dimensions). The energy flux density corresponding to these conditions is $q = q_0 \approx 10^6$ W/cm^2. Obviously, we have not exhausted the possibilities for optimizing the conditions; in particular, a lens having a longer focal length might be useful. However, under our conditions, a reduction of the energy flux density from q_0 by a factor of only 1.5 leads to both the disappearance of the film and the disappearance of the hole from the target (the laser radiation leaves only a slightly fused trace). This latter result is apparently due to the circumstance that the coefficient for the reflection of the radiation from the target surface is a strong function of the state of the surface and of the value of q (ref. 13). Increasing the energy flux density to a value only twice q_0 leads to a sharp degradation of the film quality.

4. It is worthwhile to compare the experimental value of q_0 with the theoretical estimate of the flux density corresponding to the beginning of evaporation, derived in ref. 13. We adopt the following equation for evaluating the flux density which leads to a significant evaporation of material, q^*:

$$q^* = \frac{T^* \sqrt{\pi c_l \varkappa_e}}{2\sqrt{t_0}},$$

where $T^* = (\lambda A)/10R$ is the characteristic temperature, λ is the heat of evaporation, A is the atomic weight, R is the universal gas constant, c_l is the specific heat of the lattice per unit volume, and $\varkappa_e$ is the electronic thermal conductivity. This equation yields $q^*_{Cu} = 3 \cdot 10^5$ W/cm^2 and $q^*_{Si} = 1.5 \cdot 10^5$ W/cm^2.

Because of the known arbitrariness in the specification of T^*, corresponding to the beginning of significant evaporation, we calculate q_0 within the framework of the theory of thermal conductivity, using data on the saturation vapor pressure of Cu and Si (ref. 15). If we define the time which elapses from the beginning of the effect of the thermal pulse to the beginning of significant evaporation, t^*, in terms of the temperature $T(t^*)$, at which we have

$$q_v = \lambda \dot{m} [T(t^*)] = 0.5q,$$

where q_v is the heat loss due to evaporation, $\dot{m}$ is the evaporation rate, and q is the radiation flux density of the target surface, we can show that with $t_0 \sim 10^{-3}$ sec and $q \geq 10^6$ W/cm^2 we would have $t^* \ll t_0$.

Accordingly, for a free-running laser and for the radiation flux densities used in our experiments, the evaporation can be assumed quasisteady-state, and q_0 can be evaluated from the simple equation (we asssume a rectangular laser pulse)

$$q_0 = \frac{\gamma \lambda h}{t_0},$$

where γ is the density of the target material, h = (0.1-0.2)d, and d is the diameter of the laser beam at the target surface.

For the values of h_{Cu} and h_{Si} taken from Table 1, this equation yields $q_0Cu = 1.6 \cdot 10^6$ W/cm^2 and $q_{0Si} = 10 \cdot 10^6$ W/cm^2.

More accurate estimates would require taking account of the reflection of the radiation from the target surface and the discontinuous nature of this radiation.

Thermophoresis and diffusophoresis of small, volatile aerosol particles

Yu. I. Yalamov and E. R. Shchukin

Institute of Physical Chemistry, Moscow

(Submitted February 8, 1973; resubmitted July 9, 1973)
Zh. Tekh. Fiz., 44, 447-450 (February 1974)

The thermophoresis and diffusophoresis of small, volatile particles, i.e., particles on whose surfaces there can be appreciable condensation and evaporation of the drop material, are analyzed in the steady-state approximation. The contribution of the volatility to the force equation is shown to be directly proportional to the reciprocal of the Knudsen number; this contribution is negligibly small.

INTRODUCTION

A theory has been derived for the thermophoresis and diffusophoresis of small, nonvolatile aerosol particles[1-5] ($Kn = \lambda/R > 1$). Here, "volatile aerosol particles" are those on whose surfaces the aerosol material can condense and evaporate; in certain cases, e.g., water droplets in air, these processes can be important.

Since the volatility strongly influences the motion of moderately large and large volatile particles,[4,6-14] it is worthwhile also to analyze the motion of small volatile particles; we take up this problem below in the steady-state approximation.

CALCULATION OF THE FORCE AND VELOCITY OF THERMODIFFUSOPHORESIS

We consider a small spherical particle of radius R ($Kn = \lambda/R > 1$) suspended in a binary gaseous mixture with mean free path λ, an inhomogeneous distribution of the temperature T, and a density n_{10}. One component of the mixture (in our case the first component, n_1) consists of molecules of the same material as the drop. The temperature and density gradients of the gaseous mixture are small enough so that we can use the distribution function for the gas molecules in the first approximation in the temperature and density gradients.

We analyze the particle motion in a coordinate system fixed at the center of mass of the mixture.

As the particle moves it experiences a thermodiffusophoretic force $\mathbf{F}_{TD}$ due to the temperature and density gradients, and it experiences the drag of the medium, $\mathbf{F}_u$. The total force, equal to the sum of $\mathbf{F}_{TD}$ and $\mathbf{F}_u$, is found in the kinetic theory of gases by integrating the momentum flux of the molecules incident on the drop over the surface of the drop:[1-5,15]

$$\mathbf{F} = -\sum_i \int ds \sum_{\mp} \int d\mathbf{v}_i \mathbf{v}_i \mathbf{v}_i m_i f_i^{\mp}, \tag{1}$$

where $f_i^{\mp}$ are the distribution functions of the incident (−) and reflected (+) molecules, and m_i and $\mathbf{v}_i$ are the mass and velocity of molecules of species i.

Taking account of the smallness of the influence of a particle on the distribution of molecules in the surrounding gas,[1-5,15] for simplicity we adopt a volume distribution function for the incident molecules in the approximation based on the first two Sonine polynomials:[16]

$$f_i = n_i \left(\frac{m_i}{2\pi kT}\right)^{3/2} \exp\left(-\frac{m_i v_i^2}{2kT}\right)\left\{1 - \frac{m_i}{kT}\mathbf{v}_i\mathbf{u} - \left[(-1)^{i-1}\frac{d_0\rho_1\rho_2}{\rho n_i m_i^{1/2}} + d_{(-1)^{i-1}} S^1_{3/2}\left(\frac{m_i}{2kT}v_i^2\right)\right]\sqrt{\frac{m_i}{2kT}}\,\mathbf{v}_i \nabla n_{10} - \left[(-1)^{i-1}\frac{a_0\rho_1\rho_2}{\rho n_i m_i^{1/2}} + a_{(-1)^{i-1}} S^1_{3/2}\left(\frac{m_i}{2kT}v_i^2\right)\right]\sqrt{\frac{m_i}{2kT}}\,\mathbf{v}_i \nabla \ln T\right\}. \tag{2}$$

In Eq. (2), T is the temperature of the gas surrounding the particle; n_i is the number density of molecules of species i (per unit volume); $\rho_i = m_i n_i$; $\rho = \rho_1 + \rho_2$, $n = n_1 + n_2$; $n_{10} = n_1/n$; $S^1_{3/2}$ is the Sonine polynomial;[16] a_0, d_0, $a_{(-1)^{i-1}}$ and $d_{(-1)^{i-1}}$ are quantities which are functions of the nature of the interaction of the molecules and the thermodynamic properties of the medium, which are expressed in terms of the coefficients a_{ik} calculated in ref. 16; k is the Boltzmann constant.

Assuming that some of the molecules of the second species are reflected diffusely and some undergo specular reflection with a tangential-momentum accommodation coefficient q_2 (refs. 1-5), we seek the distribution function at the surface of the particle, f_2^+, in the following form:

$$f_2^+ = q_2 f_{2w}^0 + (1 - q_2) f_2^- [\mathbf{v}_2 - 2\mathbf{n}_r(\mathbf{n}_r\mathbf{v}_2)], \tag{3}$$

where f_{2w}^0 is a local Maxwellian distribution and $\mathbf{n}_r$ is the unit vector along the outward normal.

In the equation for the distribution function for molecules of the first species escaping from the surface of the particle we have taken account of the circumstance that the relative number of molecules which are evaporated from the surface of the drop material in a diffuse distribution is proportional to the coefficient α_m and that the relative number of incident molecules which undergo specular reflection is proportional to $(1-\alpha_m)$ (refs. 16, 17, 19):

$$f_1^+ = \alpha_m n_{1s} \exp\left(\frac{2V_1 l}{RkT_s}\right) \exp\left\{\frac{-m_1 v_1^2}{2kT_s}\right\} \left(\frac{m_1}{2\pi kT_s}\right)^{3/2} + (1 - \alpha_m) f_1^- [\mathbf{v}_1 - 2\mathbf{n}_r(\mathbf{n}_r\mathbf{v}_1)], \tag{4}$$

where α_m is the mass accommodation coefficient,[16,19] T_s is the temperature at the given point on the particle surface, n_{1s} is the saturation vapor density of the drop material above the plane of the surface at T_s, V_1 is the volume per molecule in the solid or liquid phase of the aerosol particle, and l is the surface tension.

Solving Eq. (5) (which follows) for the temperature distribution in the interior of the particle, T_k, and using the system of boundary conditions (6), (7), we find the distributions of the quantities T_{w2}, n_{w2}, and $T_s = T_k|_{r=R}$ by introducing the energy accommodation coefficient γ_2 and taking account of the difference between T_{w2} and T_s:

$$\Delta T_k = 0, \tag{5}$$

$$(\mathbf{N}_2\mathbf{n}_r) = 0, \tag{6}$$

$$\mathbf{n}_r(\mathbf{E}_2 + \mathbf{E}_1 + L m_1 \mathbf{N}_1) = -\varkappa_k(\mathbf{n}_r \nabla T_k)|_{r=R}, \tag{7}$$

where

$$\mathbf{N}_i=\int d\mathbf{v}_i\mathbf{v}_i f_i;\quad \mathbf{E}_i=\int d\mathbf{v}_i\mathbf{v}_i\frac{m_i v_i^2}{2}f_i, \tag{8}$$

n_r is the unit vector along the outward normal, $\varkappa_k$ is the thermal conductivity of the particle material, L is the latent heat of evaporation at $T = T_S$ (refs. 1, 6, 17, 18), and T_{W2} and n_{W2} are the distributions over the particle surface of the temperature and density of reflected molecules of the second species.

Condition (6) takes account of the fact that molecules of the second species do not penetrate the surface of the particle, while condition (7) expresses conservation of the energy flux across this surface. This energy flux consists of terms proportional to the temperature and density gradients, which appear in the expression for $(E_1 + E_2)$; account is taken of the heat of the phase transition at the given point, Lm_1N_1.

Substituting the values found for T_{W2}, T_S, and n_{W2} into Eqs. (3) and (4), and integrating (1), we find the total force to be

$$\mathbf{F}=\mathbf{F}_{TD}+\mathbf{F}_u, \tag{9}$$

where

$$\begin{aligned}\mathbf{F}_{TD}=&-\frac{4}{3}\sqrt{\pi}R^2kT\left\{\frac{2d_0\rho_1\rho_2}{\rho}\left[\frac{(1+\delta_{11})}{\sqrt{m_1}}-\frac{(1+\delta_{21})}{\sqrt{m_2}}\right]-[d_1n_1(1+\delta_{12})\right.\\&\left.+d_{-1}n_2(1+\delta_{22})]+\Theta_{11}R\right\}n\nabla n_{10}\\&-\frac{4}{3}\sqrt{\pi}R^2kT\left\{\frac{2a_0\rho_1\rho_2}{\rho}\left[\frac{(1+\beta_{11})}{\sqrt{m_1}}-\frac{(1+\beta_{21})}{\sqrt{m_2}}\right]\right.\\&\left.-[a_1(1+\beta_{12})+a_{-1}(1+\beta_{22})]-\Theta_{22}R\right\}\nabla\ln T.\end{aligned} \tag{10}$$

In (10) we use

$$\delta_{11}=\alpha_m\frac{\pi}{8}\frac{kn_2}{\varkappa_k}\sqrt{\frac{2kT}{\pi m_1}}\left[\frac{5}{2}+\frac{Lm_1}{kT}\right]pR, \tag{11}$$

$$\delta_{12}=\alpha_m\frac{5}{16}\pi\frac{kn_2}{\varkappa_k}\sqrt{\frac{2kT}{\pi m_1}}\,pR, \tag{12}$$

$$\beta_{11}=\delta_{11};\ \beta_{12}=\delta_{12};\ \beta_{21}=\delta_{21};\ \beta_{22}=\delta_{22}, \tag{13}$$

$$\left.\begin{aligned}\delta_{21}=&\sqrt{\frac{T_{w2}}{T}}\frac{\pi}{8}\delta_2+\delta_2(1-\gamma_2)\frac{\pi}{64}\sqrt{\frac{T}{T_{w2}}}\\&+\frac{\pi}{8}\gamma_2\delta_2\frac{kn_2}{\varkappa_k}\sqrt{\frac{2kT}{\pi m_2}}\left(\frac{5}{4}-\frac{T_s}{T}\right)pR,\end{aligned}\right\} \tag{14}$$

$$\delta_{22}=\frac{5}{32}\pi\delta_2(1-\gamma_2)\sqrt{\frac{T_{w2}}{T}}+\frac{5}{16}\pi\gamma_2\delta_2\frac{kn_2}{\varkappa_k}\sqrt{\frac{2kT}{\pi m_2}}\,pR, \tag{15}$$

$$\Theta_{11}=\left[(1-\alpha_m)-(1-\delta_2)-\sqrt{\frac{T_{w2}}{T}}\delta_2\right], \tag{16}$$

$$\Theta_{22}=\frac{n_2}{2}\gamma_2\delta_2\sqrt{\frac{T_{w2}}{T}};\quad \Theta_{33}=\frac{5}{4}+\frac{Lm_1}{2kT} \tag{17}$$

$$\left.\begin{aligned}p=&\left\{\frac{\delta_2\gamma_2}{2}\sqrt{\frac{T_{w2}}{T}}+\alpha_m T_s\frac{n_{1s}}{n_2}\right.\\&\left.\times\exp\left(\frac{2V_1l}{RkT_s}\right)\left[\frac{d\ln n_{1s}}{dT_s}-\frac{2V_1l}{RkT_s^2}+\frac{1}{T_s}\right]\right\}.\end{aligned}\right\} \tag{18}$$

The viscous force is

$$\begin{aligned}\mathbf{F}_u=&-\frac{8}{3}\sqrt{2\pi kT}R^2\left\{n_2\sqrt{m_2}\left[1+\frac{\pi}{8}\sqrt{\frac{T_{w2}}{T}}\delta_2\right.\right.\\&\left.+\frac{\pi}{64}\delta_2(1-\gamma_2)\sqrt{\frac{T}{T_{w2}}}+\frac{\pi}{8}\gamma_2\delta_2\frac{n_2k}{\varkappa_k}\sqrt{\frac{2T}{\pi m_2}}\,pR\left(\frac{5}{4}-\frac{T_s}{T}\right)\right]\\&\left.+n_1\sqrt{m_1}\left[1+\frac{\pi}{8}\alpha_m\Theta_{33}\frac{kn_2}{\varkappa_k}\sqrt{\frac{2kT}{\pi m_1}}\,pR\right]\right\}\mathbf{u}.\end{aligned} \tag{19}$$

In Eqs. (10)-(19), a_0, d_0, and $a_{\pm1}$, $d_{\pm1}$ are constants governed by the masses of the gas molecules, m_1 and m_2, and the nature of the interaction between them: they are expressed in terms of the coefficients a_{ik} calculated in ref. 16. Also, $\bar{T}$, $\bar{T}_S$, and $\bar{T}_{W2}$ are the average temperatures of the medium, the aerosol particle, and the molecules of the second species reflected from the surface of the particle; n_1 and n_2 are the average number densities (per unit volume) of molecules of the first and second species; $n = n_1 + n_2$; $n_{10} = n_1/n$; and $(dn_{1S})/(d\bar{T}_S)$ is the derivative of the saturation vapor density above the plane of the surface with respect to the temperature at $\bar{T}_S$. The particle velocity can be found by setting Eq. (9) equal to zero.

The average temperature of the drop surface, $\bar{T}_S$, and that of the reflected molecules of the second species, $\bar{T}_{W2}$, are found from Eqs. (20) and (21):

$$\begin{aligned}&\gamma_2\delta_2n_2\sqrt{\frac{T}{m_2}}k[T_s-T]+\alpha_m\frac{k}{\sqrt{m_1}}\left[n_{1s}(T_s)T_s^{3/2}\exp\left(\frac{2V_1l}{RkT_s}\right)-n_1T^{3/2}\right]\\&+\alpha_m\frac{L\sqrt{m_1}}{2}\left[n_{1s}(T_s)\exp\left(\frac{2V_1l}{RkT_s}\right)T_s^{1/2}-n_1T^{1/2}\right]=0,\end{aligned} \tag{20}$$

$$T_{w2}=\gamma_2T_s+(1-\gamma_2)T. \tag{21}$$

DISCUSSION OF RESULTS

We have derived equations for the thermodiffusophoretic force and the drag force of the medium, taking account of the effects of volatility.

At a vanishing temperature gradient these equations become the equations for pure diffusophoresis of volatile particles, and with $n_1 = 0$, $a_0 = 0$, and $a_1 = 0$ they become the equations for the thermophoresis of volatile particles.

We see from Eqs. (10)-(19) that the contribution of the volatility effects to the force equations is proportional to R/λ. Numerical estimates, on the other hand, show that the contribution of volatility effects for substances of practical interest is less than 1%, and in an estimate of the forces exerted on volatile particles we can use the equations found above for nonvolatile particles, setting $q_1 = 0$.

Electron spectrometer for electric excitation of nuclei in a storage ring

D. M. Nikolenko and S. G. Popov

(Submitted September 18, 1972; resubmitted April 12, 1973)
Zh. Tekh. Fiz., 44, 451-456 (February 1974)

A magnetic electron spectrometer with 180° focusing and a wide energy range is described. The spectrometer uses wire spark chambers. The instrument is used for experiments on electric excitation of nuclei in a storage ring and has been calibrated at the VÉP-1 storage ring. The resolution (half-width of the peak for elastically scattered electrons) is 160 keV for a 40-MeV beam. Certain other experiments which can be carried out with a storage ring with an internal target are discussed.

Considerable progress has been recently made in the study of the properties of atomic nuclei by means of electron scattering. The interest in such experimental methods is based on the fact that the interaction of electrons with nuclei is amenable to an accurate theoretical description and on the fact that electron scattering offers far more possibilities than photonuclear reactions.[2] Exact experiments have been made possible by the development of linear accelerators, which provide strong particle beams with a relatively low energy spread. The development of electron storage devices also opens up new possibilities in this field.[3-5] Because of radiation damping the energy spread of the electron beam in a storage ring is small ($\sim 10^{-4}$ in existing devices) and is not affected by the introduction of a very thin target. Nevertheless, the "effective thickness" (the product of target thickness and the number of times an electron crosses it) can be as high as 0.2 radiation length units.[3]

A very thin target, for example consisting of a stream of gas or vapor, makes it possible to reconstruct the kinematics of scattering processes involving secondary low-energy particles and heavy particles. The recoil nucleus can be regarded as such a secondary particle. Kinematic considerations[6] indicate that for a fixed electron scattering angle the recoil nuclei are emitted in the same direction both in pure elastic scattering and in scattering involving the emission of bremsstrahlung γ photons (to within $\sim 1/\gamma$, where γ is the relativistic factor and the energy of the recoil nucleus is neglected). Recoil nuclei, excited in inelastic scattering, move at an angle φ to this direction. The angle can be found from

$$\operatorname{tg}\varphi = \frac{p - p'}{2p}\operatorname{ctg}\frac{\theta}{2},$$

where θ is the angle of the scattered electron, p and p' are the electron momenta before and after scattering. Using the anticoincidence mode with "elastic" recoil nuclei, or the coincidence mode with "inelastic" nuclei, it is possible to eliminate the bremsstrahlung background in inelastic scattering (see refs. 2, 7, 8).

The operating conditions of electron storage rings allow the application of wire spark chambers as detectors. This makes it possible to build a multichannel instrument with high energy resolution capable of analyzing a wide range of energies at one time. Simultaneous detection of electrons over a wide range of energies increases the rate of statistical data acquisition and facilitates the determination of relative cross sections. Thus, it is not desirable to use double focusing spectrometers, conventionally used in linear accelerators, as they only cover a narrow energy range.[8,9]

The magnetic electron spectrometer described below is intended for use in experiments on electric excitation of nuclei. The spectrometer is equipped with two wire spark chambers and the energy range $E_{max}/E_{min} \simeq 2$.

The magnetic field of the spectrometer is uniform. The two spark chambers are positioned along one line in the field. Since the field of the main magnet along the part of the electron trajectory ending at the entrance to the first chamber is compensated (by the compensating magnet 3 in Fig. 1) so that electrons of any energy crossing this path can suffer only a parallel displacement, the electrons cross the first spark chamber in the direction they have when leaving the target. The radius of an electron in the field of the main magnet is given by $R = R_0/\cos\alpha$, where $R_0 = (x_1 + x_2 + L)/2$, x_1 and x_2 are coordinates of the electron in the first and second chamber, respectively, L is the distance between the origins of the x_1 and x_2 coordinates (Fig. 1), and α is the angle between the direction of motion of an electron through the first chamber and the normal to the plane of the wire electrode of the chamber (entrance angle into the first chamber). This angle is determined from the coordinate x_1 assuming a point target and calculating the parallel displacement for any specific electron energy.

The stray fields of the main and compensating magnets provide edge focusing of electrons in a direction normal to the magnet pole plane. The electrons are focused primarily by the compensating magnet when leaving its field and entering the field of the main magnet. The focal

length is estimated as ~ 1 m for particles of maximum energy. Since the spectrometer chamber measures two electron coordinates (x and y, y being the coordinate normal to the magnet pole plane), it is possible to determine the focal length experimentally. The obtained result agrees with the estimate. Knowing y_1 and y_2 for the electron allows us, if necessary, to take account of the transverse electron-momentum component in calculating the electron energy.

The spectrometer design has been described in ref. 4 and is similar in many details to that described in ref. 10. The following two changes have been made: To reduce the error in entrance angle determination caused by multiple scattering, the entrance foil of the spectrometer has been brought out to the storage ring foil, and the compensating magnet has been made with parallel poles of 30 × 200 mm with a 20 mm gap between them. The wire chambers have a glass textolite frame. The grounded wires for determining the electron flight coordinates x_1, x_2 are wound with a 0.5 mm pitch. The high-voltage electrode wires, which determine the y_1, y_2 coordinates, are parallel to the grounded wires and have a 1 mm pitch. The electrode gap is 7 mm. The spark chambers are filled with helium at atmospheric pressure with an admixture of 2% ethyl alcohol. The high-voltage pulse applied to the spark chamber has an exponential shape (time constant of 1.6 μsec) and an amplitude of 5.5 kV. The second chamber is separated from the first by a light shield. The apertures of the entrance and exit chambers are respectively 26 × 155 and 38 × 450 mm. The maximum electron radius in the main magnet field is limited by the construction and by the size of the useful magnetic-field region and is about 30 cm. Thus, $R_{\max}/R_{\min} \simeq 2$ (L = 130 mm).

The spectrometer has been tested on the VÉP-1 storage[1] ring with an electron beam energy of 40 MeV. The targets are a chemically pure aluminum foil and a shaped stream of water vapor at a pressure of about 10^{-4} torr striking a liquid-nitrogen trap. The second case corresponds to the so-called hyperfine target (see ref. 3). The spectrometer has been located so that the first chamber is approximately one meter from the target. The solid angle of the spectrometer is then approximately $2 \cdot 10^{-3}$ sr.

The VÉP-1 and spectrometer magnet coils, connected in series, are supplied from a single motor generator. The coil current is electronically stabilized. The magnetic fields are monitored by a nuclear magnetic resonance apparatus.

Figure 1 shows a block diagram of the experiment. An electron scattered in the target passes through the magnetic system of the spectrometer and is detected by the scintillation counter 6; to reduce false triggering by noise, the counter has two photomultipliers 9 connected to a fast coincidence circuit 10. The counter triggers the high-voltage pulse generator 11, which feeds the spark chambers. The sampling (ferrite memory cube 13) and tape-punching system 14 operates only when both spark chambers 8 fire simultaneously. The information is fed to a digital computer.

Firing of the spark chamber is indicated by pulses taken from the secondary winding of a ferrite-core transformer 15, whose primary carries the high-voltage pulses. Pulses from the secondary windings are shown in Fig. 2 (top waveform). The left- and right-hand photographs were taken before and after chamber firing respectively. The pulse in Fig. 2a is due to current charging the chamber capacitance when the high-voltage pulse is applied. The first pulse in Fig. 2a' is due to the same cause while the second is produced by the current surge during chamber breakdown. The time T between these two pulses corresponds to the breakdown development in the chamber. The bottom waveforms in Fig. 2 show the same pulses after passing the integrating circuit (17 in Fig. 1); it is seen that after chamber firing the pulse has a much higher amplitude and can be easily identified in the discriminator (16 in Fig. 1).

It should be noted that when the chamber is triggered by light produced in breakdown of the second chamber (this effect has been discussed in ref. 10), T is much longer than when breakdown is initiated by a particle (see Table 1). This feature can be exploited in systems using many chambers in which the use of light shields is undesirable.

The spectrometer resolution is affected by the following factors: spatial resolution of the chamber, displacement of the electron from its ideal trajectory as a result of multiple scattering in the chamber gas, uncertainty of the entrance angle to the first chamber, fluctuation of ionization loss in the VÉP-1 and spectrometer foils and in the chamber gas, and inhomogeneity of the main magnet field.

These effects have been estimated as follows.

1. The spatial resolution of the chambers has been measured and found to be equal to $(\Delta x^2)^{1/2} = 0.30$. The contribution to the spectrometer resolution is

$$\frac{\Delta E}{E} = \left(\frac{\overline{\Delta x^2}}{2R^2}\right)^{1/2},$$

where R is the radius of particle trajectory in the magnetic field.

2. If the electron displacement due to multiple scattering in gas is calculated from the simplified dependence of the mean-square angle $\overline{\theta^2}$ on the path traveled in gas:

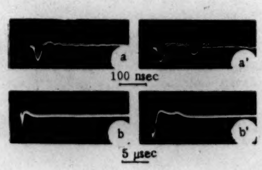

Fig. 2

TABLE 1. Time of Breakdown Development in Spark Chamber (in nsec)

	U, kV			
	6.6	6.0	5.5	5.0
Particle initiated	70	80	120	170
Light initiated	20	170	250	400

$\overline{\theta^2} = k(l/E^2)$ (where l is the length of the path), then taking into account 180° scattering we have

$$\frac{\Delta E}{E} = \frac{1}{E}\left(k\frac{\pi R^3}{8}\right)^{1/2}.$$

3. The energy error due to the uncertainty of the entrance angle to the first chamber is $(\Delta E)/E = \tan\alpha(\overline{\Delta\alpha^2})^{1/2}$. The error in the angle α results from multiple scattering in the foils and gas in front of the first chamber, which is due to the fact that the extended target does not allow full compensation of the stray fields.

Table 2 shows the individual contributions of the various factors in the spectrometer resolution (σ is the mean-square deviation) for an electron energy 40 MeV and R = 28 cm; the table also lists the energy spread of the storage ring beam and the overall resolution of the experiment.

Figure 3 shows peaks for elastically scattered electrons. The two bottom curves have been obtained with the compensating magnet switched off. The entrance angles α at the first chamber are in this case considerable (14° on the average). Curve c has been plotted assuming that the distance between the flight coordinates in the spark chamber is equal to the diameter of trajectory of particles in a magnetic field. Curve b shows the spectrum of the same electrons corrected for the entrance angle approximately calculated from the entrance coordinate at the first chamber. The topmost curve has been obtained with the compensating magnet in operation. The experimental curve is in this case asymmetric. The resolution determined from the left-hand drop of the curve is in good agreement with the calculated resolution (Table 2).

TABLE 2

Factor	σ, keV
Entrance angle error	10
Spatial resolution of chambers	30
Displacement of electrons because of multiple scattering	40
Fluctuation of ionization loss	5
Nonuniformity of main magnet field	5
Spectrometer resolution	50
Energy spread of storage ring beam	30
Overall resolution	60

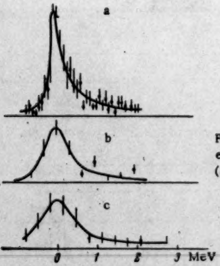

Fig. 3. Peaks of elastically scattered electrons: σ = 65(a), 200 (b), and 500 (c) keV; Al^{27}, 40 MeV, 128°.

The asymmetry of the peak is significantly affected by the loss of energy of electrons passing through the wires of the first chamber. Thus, with 0.1 mm bronze wires, 26% of all electrons pass through one wire and lose a total of 180 keV. Figure 4 shows electron peaks obtained with 0.1 bronze wires (1) and 0.03 nichrome wires (2) in the first chamber. To facilitate comparison different scales are used so that the peak heights are the same. The left sides of the peaks practically coincide. The right side of the peak is lower with thin wires than with the thicker ones. The half-widths are 160 and 200 keV respectively. A water vapor target (2) gives a peak due to electrons elastically scattered by hydrogen.

As is evident from Table 2, the contribution of the energy spread of the storage ring beam into the overall resolution is not dominant. Moreover, if the beam energy is increased up to some limit (approximately 100 MeV), there is even an absolute decrease in energy spread. For example, for a VÉP-1 beam of 100 MeV and 30 sec lifetime,[11] σ = 15 keV. Thus, there are good reasons for improving the spectrometer resolution.

One of the possible ways to improve resolution is to reduce the effect of multiple scattering on the path between the two chambers. This can be achieved by gas filling only a small volume of the spectrometer between the two chambers. Since it is important that the material traversed by electrons be as thin as possible, particularly in the first chamber, a thin lavsan film is indicated. The construction can be facilitated by using argon at a low pressure in the chambers.[12] As indicated above, the resolution is proportional to $R^{3/2}$ with respect to electron displacement by multiple scattering, and to $1/R$ with respect to spatial resolution of the chambers. If the first effect is eliminated, the radius of electron trajectory in the magnetic field can be increased so that the contribution of spatial resolution of the chambers into the overall spectrometer resolution is minimized.

The authors thank V. A. Kabannik and A. P. Chabanov for help with the experiments, V. A. Semenychev for building the spark chambers, and all laboratory workers who contributed to this work. The authors also are indebted to A. P. Onuchin for useful comments.

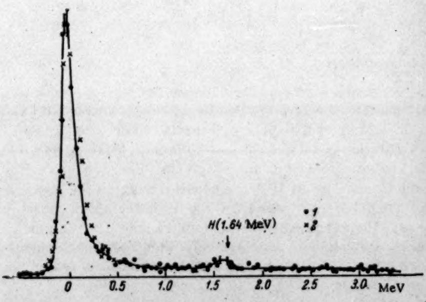

Fig. 4. Electron peaks obtained with 0.1 mm bronze wires (1) and 0.03 mm nichrome wires (2) in the first chamber: 1) Al^{27}, 40 MeV, 52°, $\Gamma_{1/2}$ = 200 keV; 2) O^{16} (H_2O), 40.5 MeV, 90°, $\Gamma_{1/2}$ = 160 keV.

Strobe unit for measuring luminescence in the range 10^{-7}-$2 \cdot 10^{-10}$ sec

V. A. Bonch-Bruevich and N. A. Tolstoi

(Submitted May 18, 1973)
Zh. Tekh. Fiz., 44, 457-462 (February 1974)

A method of measuring luminescence relaxation times τ in the range 10^{-7}-$2 \cdot 10^{-10}$ sec is described. The time scale of the investigated signals is linearly transformed by means of a sampling oscilloscope, and subsequent measurement of τ is performed with a low-frequency unit. Storage methods are used in the low-frequency part of the device to improve the signal-to-noise ratio.

The value of information on the kinetics of induced physical phenomena (photoconductivity, luminescence, populations of energy levels, and so on) is well known. The increasing interest in such phenomena has given rise to a demand for a technique for investigating transient processes that is capable of extension to ever-increasing ranges of the measured parameters, especially the relaxation time τ. One important requirement is that the technique be convenient and simple.

The taumeter technique[1] is one of the simplest and most effective ways[1)] of measuring τ. Proposed in 1947 (initially for the range 10^{-1}-10^{-5} sec), this technique has been developed greatly over the last 25 years. In particular, instruments have been built utilizing a mechanical light modulator[2] (10^{-1}-10^{-7} sec), an electrooptical light modulator[2] (10^{-5}-10^{-8} sec), the IS-3 flash lamp[3] ($5 \cdot 10^{-6}$-$2 \cdot 10^{-8}$ sec), etc. Such embodiments of the taumeter technique have been the basis of many investigations on the kinetics of induced phenomena.

The main feature and advantage of the taumeter technique is that the values of τ accessible to correct measurement can be one and a half orders smaller than the times characterizing the intrinsic time delay of the apparatus used (rise time of exciting pulses, photomultiplier, and oscilloscope delay). This important property is directly connected with the "functional balance" or "null" character of the taumeter method of measurement. The analog nature of the taumeter method, in which the investigated relaxation process induced by an exciting pulse is swept on an oscilloscope screen by the process induced in an analog RC circuit by the same exciting pulse, in effect eliminates the delay introduced by the measuring apparatus. Apparatus delay does not introduce errors into the measurements but only reduces the sensitivity of the method. Since the initial sensitivity is extremely high (we have in mind the sensitivity of the method under conditions when the delay is negligible compared with τ), the real sensitivity remains satisfactory, even when the delay is 30-40 times greater than the delay of the process under investigation.

A second important property conferred by the analog nature of the method is that the shape of the exciting pulse plays a comparatively small role: The pulse need not be rectangular. It is sufficient that the pulse have at least one steep edge, which, as is well known, is a characteristic of flash lamps. The essence of the matter is that the differential (kinetic) equation of an exponentially relaxing process and the differential equation of an electrical RC circuit are formally identical. When RC = τ an RC integrating circuit distorts any exciting pulse in the same manner as the investigated object, so that the taumeter loop on the oscilloscope screen degenerates into a straight line for any shape of exciting pulse.

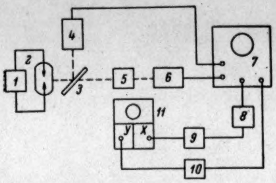

Fig. 1. Block diagram of strobing ultrataumeter. 1) Flash lamp power supply; 2) flash lamp; 3) beam-splitting plate; 4) X-channel photomultiplier; 5) investigated object; 6) Y-channel photomultiplier; 7) S1-39 sampling oscilloscope; 8) taumeter measuring circuit; 9) X-channel storage device; 10) Y-channel storage device; 11) S1-19 oscilloscope.

The present paper describes an ultrataumeter utilizing standard elements, in which effective use is made of the above features.

A block diagram of the ultrataumeter is shown in Fig. 1. The main component is a two-channel S1-39 sampling oscilloscope with a 0.7 GHz response which is used to expand the time scale. Luminescence is excited in the investigated object by a DKSSh-120 xenon flash lamp operating in a regime of high-voltage periodic self-breakdown. By suitably choosing the parameters of the discharge circuit of the lamp (discharge capacitance about 50 pF) the length of the leading edge of the radiation pulse can be reduced to 3 nsec. The length of the trailing edge is an order of magnitude longer. The repetition frequency of the pulses (1-2 kHz) is set by the supply voltage (10-15 kV). A beam-splitting plate forms two light beams. One of these beams excites the luminescence of the sample, located in the "main" Y channel of the taumeter. The other beam is used to produce an analog signal in the sweep (X) channel. The required regions in the lamp emission spectrum and in the luminescence spectrum of the sample are selected by glass light filters. Two photomultipliers of the same type serve as light receivers. The signals from the photomultipliers of the two channels are fed to the inputs of the S1-39 sampling oscilloscope. The envelopes of the peaks of the low-frequency pulses removed from the S1-39 outputs constitute the time-transformed main and sweep signals. The main Y signal is then fed to a storage device and then to the Y input of an S1-19 oscilloscope. The sweep (X) signal passes through a calibrated RC circuit with variable R and C (the measuring circuit of the taumeter) to a storage device and then to the X input of the S1-19 oscilloscope, in which the sweep unit is replaced by a preamplifier identical to the preamplifier of the Y channel. The screen of the S1-19, on which the envelope of the Y signal is swept by the envelope of the X signal, is used to monitor the straightening out of the taumeter loop. The storage devices are RC integrating circuits with variable time constants and cathode followers at the inputs.

The two channels of the device as a whole are balanced (by adjusting optical distances, cable lengths, photomultiplier power supplies, time constants of storage devices in both channels) until, at an RC of the taumeter circuit equal to zero and both photomultiplier cathodes illuminated by the same light pulse, a straight line is obtained in place of a loop on the screen of the S1-19.

Thus, the main and the sweep signals are functionally balanced after transformation (slowing down) of their time scale by many orders of magnitude, for example, from the nanosecond to the millisecond region. At the same time the storage devices greatly enhance the signal-to-noise ratio.

The oscillograms of Figs. 2 and 3 illustrate the features and the possibilities of the method. The role played by the storage devices is seen clearly. In principle, the storage devices degrade the time resolution of the method; however, the improvement in the signal-to-noise ratio is so large that the time resolution actually improves when they are used. The optimum value of the time constant of the storage devices is different under different measurement conditions but can be set up without difficulty.

In a measurement of τ (equal to 4 nsec) of an alcohol solution of rhodamine C (Fig. 2d) the time resolution of the method with FÉU-28 photomultipliers is better than ± 1 nsec. Indeed, as Figs. 2e and f show, insertion into the taumeter circuit of RC values of 5 or 3 nsec results in the appearance of distinct loops. Figures 2h and i show that τ can be measured by the described method in signals with a signal-to-noise ratio of the order of unity. We note that the time resolution of the method is mainly determined by the transient response of the FÉU-28, which is by no means the optimum photoreceiver for time measurements.

The time resolution is considerably enhanced by using FÉU-30 photomultipliers. For example, in a measurement of the $\tau = 6.4$ nsec of an alcohol solution of 4-methylamino-N-methylphthalimide[4] (Fig. 3a), distinct loops are observed for a taumeter imbalance of 0.2 nsec (Fig. 3b, c). The time resolution here is now determined by the delay of all the components of the setup and is estimated as ± 0.1 nsec.

We note that different true time delays in the X and Y channels, which should not be confused with different response times of the channels, also result in the formation of loops on the oscilloscope screen. Figure 3e shows such a loop, obtained by increasing the path of the light in the Y channel of an initially balanced system by 30 cm, which

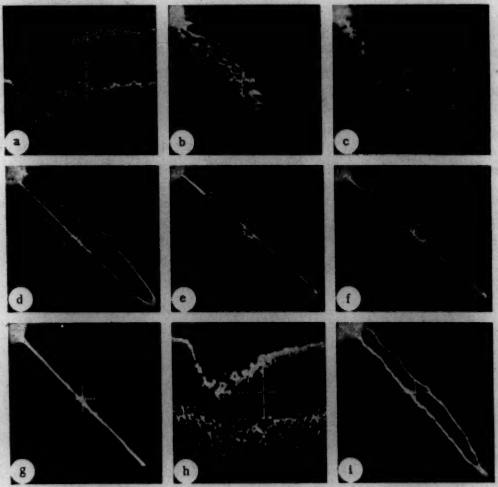

Fig. 2. Oscillograms illustrating operation of strobing ultrataumeter with FÉU-28 photomultipliers. a) Signals in X and Y channels of balanced device observed on screen of S1-19 sampling oscilloscope (scales: 20 nsec/div along horizontal, 200 mV/div along vertical); b) line observed on S1-19 screen on sweeping signals of oscillogram (a) one with the other (storage devices off); c) loop from sample with τ = 4 nsec (storage devices off); d) same as c, but with storage devices on; e) loop overcompensated, 5 nsec introduced; f) loop undercompensated, 3 nsec introduced; g) loop compensated, 4 nsec introduced; h) form of signals on screen of S1-19 for large noise level in sample luminescence signal with τ = 4 nsec (lower beam), scales: 20 nsec/div along horizontal, 20 mV/div for lower and 100 mV/div for upper signal along vertical; i) loop obtained from oscillogram h.

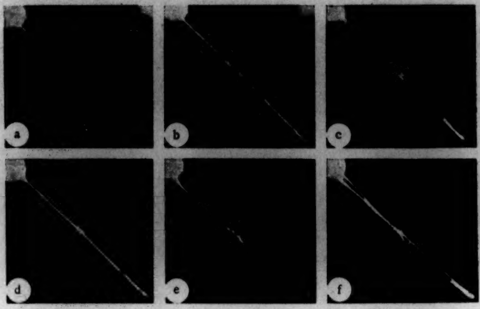

Fig. 3. Oscillograms illustrating operation of strobing ultrataumeter with FÉU-30 photomultipliers. a) Loop from sample with $\tau = 6.4$ nsec; b) undercompensated loop, 6.2 nsec introduced; c) overcompensated loop, 6.6 nsec introduced; d) compensated loop, 6.4 nsec introduced; e) loop resulting from 1 nsec optical delay in Y channel; f) an attempt to straighten the loop of oscillogram (e) by introducing RC into the X channel.

corresponds to 1 nsec. Such a loop can no longer be straightened out by introducing an RC in the X channel (Fig. 3f). A delay of 1 nsec can thus be clearly distinguished by the described method.

As an illustrative example of the quality of the measurements of the τ of fast luminophors that can be attained, we show in Fig. 4 the temperature dependence of the luminescence time constant of a Decalin solution of 3-monomethylamino-N-methylphthalimide. Parallel measurements of the luminescence efficiency η made by E. N. Viktorova, who kindly presented us with the investigated solution, give excellent coincidence of the form of the curves $\tau(T)$ and $\eta(T)$. (Figure 4 gives a rough idea of the photometric sensitivity of the method. The curve was obtained with a light flux of about 10^{16}-10^{17} photons/sec falling upon the cathode of the photomultiplier.)

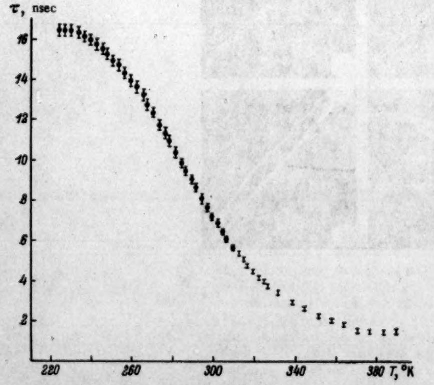

Fig. 4. Temperature dependence of luminescence time constant of Decalin solution of 3-monomethylamino-N-methylphthalimide.

Thus, the time range within the scope of the proposed method covers, to a considerable extent, the range in which phase fluorometers operate.[5] Besides simplicity and cheapness, the strobing taumeter possesses yet another promising feature: Being based on pulsed excitation it can, in principle, be used with high-power exciting sources, e.g., a laser operating in the periodic pulsed mode. This opens up at least two interesting possibilities. Firstly, investigations can be conducted in the nonlinear region, i.e., under conditions when τ depends on the intensity of the exciting radiation. Secondly, investigations can be conducted under conditions when the luminescence is extremely weak, e.g., under conditions of spectral expansion or in local investigations through a microscope. The latter is likely to be of considerable interest in connection with biological applications.

We note in conclusion that the lower time limit of the strobing ultrataumeter ($2 \cdot 10^{-10}$ sec) is probably not the ultimate. The method can probably be extended to times in the range 10^{-10}-10^{-11} sec by using faster flash lamps and better photomultipliers.

---

1) We shall concern ourselves here only with optical signals and an exponential relaxation described by a single value of τ. This covers the case of a nonexponential process approximated by an effective value of τ.

Optical characteristics of K-8 glass subject to radiation from a neodymium laser

A. M. Bonch-Bruevich, Ya. A. Imas, V. S. Salyadinov, and A. V. Shatilov

(Submitted August 23, 1973)
Zh. Tekh. Fiz., 44, 463-467 (February 1974)

The change in the bulk refractive index (Δn) of K-8 optical glass is measured while the glass is exposed to pulses from a free-running neodymium laser. The observed Δn values correspond to temperature variations of several tens of degrees at radiation fluxes which are close to the threshold for the optical breakdown of K-8 glass. The value of the absorption coefficient corresponds to the tabulated value. A possible mechanism for optical breakdown is discussed.

PROBLEM AND EXPERIMENTAL TECHNIQUE

Interferometry is used in ref. 1 to investigate the change in the refractive index (Δn) in bulk K-8 glass which has been placed into the focal plane of a lens in application of radiation from a free-running neodymium laser. Since there is no correlation between the change in the refractive index and the time-dependent structure of the laser radiation, it is concluded that the destruction of the K-8 glass takes place by a thermoelastic mechanism. Estimates of the absorption coefficient (k) are based upon calculations of the temperature of the glass volume irradiated and result in $k = 0.02\ \mathrm{cm}^{-1}$, which is higher by approximately one order of magnitude than the usual residual absorption coefficient of K-8 glass. The discrepancy can be explained by the assumption that k depends on the temperature and that it increases during the laser pulse. The value $k = 0.02\ \mathrm{cm}^{-1}$, which is obtained in experiments, must be considered an integrated characteristic averaged over the entire laser pulse. If this assumption is correct, the dependence of the temperature of the irradiated sample area on the radiation flux density must be nonlinear.

In the present work we wish to determine the nonlinear component of the refractive index. As in ref. 1, we use a Michelson interferometer to measure Δn (Fig. 1). A sample 1 of optical K-8 glass is inserted into one arm of the interferometer and irradiated with the pulses from a free-running neodymium-glass laser 2 (pulse length τ = 400 μsec). The laser is provided with a telescope-type resonator and operator under conditions close to single-mode-operation (divergence of the radiation $\Theta = 3 \cdot 10^{-4}$ rad). The radiation is focused with an optical system 3, which is composed of a cylindrical lens (f = 2320 mm) and a spherical lens (f = 280 mm) located 100 mm behind the cylindrical lens. The beam has a cross section of 0.12 × 5 mm in the focal plane of the optical system. A specially selected diaphragm 4, which is inserted behind optical system 3, provides a uniform distribution of the light flux along the focal line. The focal line is parallel to the axis of the interferometer. As a consequence, the sensitivity of the arrangement to changes in the refractive index is increased considerably. Variations in the refractive index are determined by means of the following expression:

$$\Delta n = \frac{\lambda \Delta S}{2ld}, \tag{1}$$

where l denotes the size of the optical inhomogeneity, d denotes the distance between the bands of the interference pattern, ΔS denotes the shift of a band, and λ denotes the wavelength of the illuminating radiation source. In order to eliminate from our considerations the Δn fraction related to striction, the interference pattern is photographed 0.01–0.2 sec after the radiation pulse of the neodymium-glass laser. We use a single-mode ruby laser 5 operating with single giant pulses as the illuminating source. The radiation of this laser is polarized so that the electric vector is in the plane passing through the focal line and the optical axis of laser 2 (yz plane). The Q factor is modulated with a passive shutter of KS-19 glass. The ruby laser pulse can be delayed with respect to the initiation of the radiation pulse by 100 μsec to 0.5 sec.

RESULTS AND THEIR DISCUSSION

Figure 2 shows interference patterns of optical inhomogeneities which develop at various times after the start of the pulse from the neodymium laser. The results of the quantitative evaluation of the interference patterns are indicated in Fig. 3. The interference patterns are obtained at $Q = 13.4\ \mathrm{kJ/cm^2}$ in the focal area, which is approximately one half the threshold value. The threshold at which the bulk of the glass is destroyed is about 25-30 $\mathrm{kJ/cm^2}$. It is noteworthy that when the interference pattern spreads in the course of time, the area under the Δn(x) curve is approximately constant, which means that there is a linear relation between Δn and the temperature. This conclusion agrees with the results of the calculation given below and makes it possible to determine the change in the refractive index and the temperature by the time at which the laser pulse terminates. For example, for $Q = 13.4\ \mathrm{kJ/cm^2}$, the maximum variation of the refractive index referred to the end of the laser pulse is $\Delta n = 1.4 \cdot 10^{-4}$.

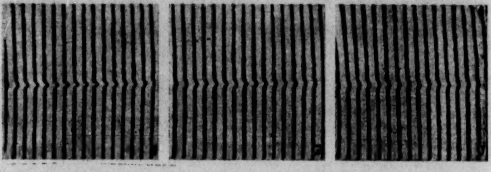

Fig. 2. Interference patterns of optical inhomogeneities at various times after the beginning of the pulse from the neodymium laser. τ_d denotes the time by which the ruby laser pulse is delayed relative to the beginning of the pulse from the neodymium laser. 2:1 scale. τ_d(msec): 1) 45; 2) 110; 3) 200; Q = 13.4 kJ/cm².

The changes of the refractive index in the heated layer consist of two components, i.e., a purely temperature-dependent component, which is usually associated with the shift of the main absorption band, and a component associated with the thermal stress:

$$\Delta n=\left(\frac{\partial n}{\partial T}\right)_\sigma \Delta T+\left(\frac{\partial n}{\partial \sigma_\parallel}\right)_T \sigma_\parallel+\left(\frac{\partial n}{\partial \sigma_\perp}\right)_T \sigma_{\perp\perp}+\left(\frac{\partial n}{\partial \sigma_{\perp\perp}}\right)_T \sigma_{\perp\perp}. \quad (2)$$

The notation is as follows: $\sigma_\parallel$ and $\sigma_\perp$ denote thermoelastic stresses, which in the yz plane are parallel and perpendicular to the vector of ruby-laser radiation, respectively; and $\sigma_{\perp\perp}$ denotes stresses perpendicular to the yz plane. Under the assumption that the entire irradiated layer is uniformly heated to a temperature T, we obtain the following expressions[2] for $\sigma_\parallel$ and $\sigma_\perp$:

$$\left.\begin{aligned}\sigma_\parallel&=-\frac{E}{1-\mu}\Delta\varepsilon_\parallel,\\ \sigma_\perp&=-\frac{E}{1-\mu}\Delta\varepsilon_\perp,\end{aligned}\right\} \quad (3)$$

where E and μ denote the elastic moduli; and $\Delta\varepsilon_\parallel$ and $\Delta\varepsilon_\perp$ denote deformations in directions parallel and perpendicular to the z axis, respectively. Obviously,

$$\Delta\varepsilon_\parallel=\Delta\varepsilon_\perp=\alpha(T-\bar{T}),$$

where α denotes the thermal expansion coefficient of the glass; $\bar{T}$ denotes the average temperature of the sample, which in the case under consideration can be replaced by the sample temperature T_0 outside the heated layer. The stress $\sigma_{\perp\perp}$ develops because the sample is compressed by an amount close to its thermal deformation $\Delta\varepsilon = \alpha\Delta T$, contrary to the case in which the heated layer fills the entire cross section area of the sample in the yz plane and, hence, the sample can freely expand in the direction of the temperature gradient (see, e.g., ref. 3). The corresponding stress is

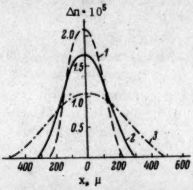

Fig. 3. Refractive index variation (Δn) of the bulk of the glass at various times after the beginning of the pulse from the neodymium laser. τ_d = (msec): 1) 45; 2) 110; 3) 200; Q* = 13.4 kJ/cm².

$$\sigma_{\perp\perp}=-E\Delta\varepsilon+\mu(\sigma_\parallel+\sigma_\perp), \quad (4)$$

where the second component accounts for the stresses acting in the yz plane. Since

$$\left(\frac{\partial n}{\partial T}\right)_\sigma\equiv\beta=2.2\cdot10^{-6}\ \text{deg}^{-1}$$

(the values of the constants were taken from refs. 4 and 5 for K-8 glass) and

$$\left(\frac{\partial n}{\partial \sigma_\parallel}\right)_T\equiv C_1=-0.5\cdot10^{-7}\ \text{cm}^2/\text{kg}\ ,$$

$$\left(\frac{\partial n}{\partial \sigma_{\perp\perp}}\right)_T=\left(\frac{\partial n}{\partial \sigma_\perp}\right)_T\neq C_2=-3.2\cdot10^{-7}\ \text{cm}^2/\text{kg}\ ,$$

we obtain finally an expression for Δn:

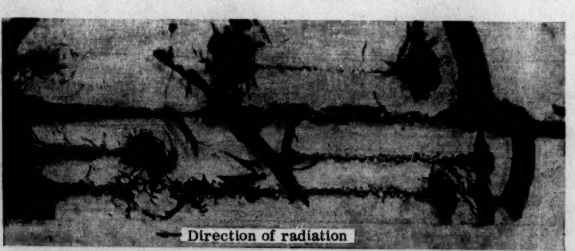

Fig. 4. Microphotographs of needle-like areas in which the K-8 glass sample is destroyed. ×40. Q* = 30 kJ/cm².

$$\Delta n = \Delta T\left[\beta + (C_1 + (2+\mu)C_2)\frac{aE}{1-\mu}\right]. \qquad (5)$$

With the above experimental value $\Delta n = 1.4 \cdot 10^{-4}$, we obtain $\Delta T = 20°C$ and, when we use the self-evident expression

$$k = \frac{\rho C \Delta T}{Q}, \qquad (6)$$

where $\rho C = 2$ kJ/cm^3·deg denotes the specific heat per unit volume of the K-8 glass, we obtain $k = 3 \cdot 10^{-3}$ cm^{-1}, which, within the error limits of the experiment and the calculations, corresponds to the calculated coefficient of residual absorption.

Under the conditions of our experiments, this k value is almost constant at least up to $Q = (0.7\text{-}0.9)Q^*$ (Q^* denotes the threshold of the energy density). Thus, it appears that the k value of ref. 1 may be too large. We note that so small ΔT values which are observed in the peak of the free-running laser at $Q \leq Q^*$ rule out the assumption that the K-8 glass is destroyed by a thermal effect. The destruction which occurs in the glass when the threshold Q^* is exceeded by 15% (Fig. 4) is in its form close to the destruction resulting from strictional self-focusing. The destruction develops when a nanosecond pulse is effective. Characteristic thin filaments develop in both cases. The appearance of these filaments may be related to the fact that the wave front of the beam is broken into areas which are self-focusing. Self-focusing increases the flux density inside individual filaments so that optical breakdown occurs.[6]

Electron energy distribution in a high-frequency discharge in an axial magnetic field

S. D. Vagner, V. A. Virolainen, Yu. M. Kagan, and T. A. Kalmykova
Karelian State Pedagogical Institute, Petrozavodsk

(Submitted July 18, 1973)
Zh. Tekh. Fiz., 44, 468-469 (February 1974)

The second-derivative method is used to measure the electron energy distribution functions in a high-frequency helium discharge. The functions are used to calculate the ionization rate. When an axial magnetic field is applied the ionization rate increases sharply from the axis of the tube towards the walls. This effect is due to a change in the radial electron energy distribution caused by the magnetic field.

In this note we consider the effect of a magnetic field on the electron energy distribution in a high-frequency helium discharge. The measurements are based on the second-derivative method[1] and are performed in a 32 mm diameter discharge tube at a current of 160 mA and helium pressures of 0.05 and 0.2 torr. The frequency of the exciting field is 25 MHz. The distance between the external ring electrodes is 35 and 20 cm. The high-frequency current is measured by means of photoelectric devices set up next to the tube electrodes. Cylindrical probes 0.2 and 0.06 mm in diameter and 3 and 5 mm long are sealed into the central part of the tube. The 0.06 mm probe can be moved radially. The probes are perpendicular to the magnetic field.[2] Two identical, symmetrically positioned, antiprobes are placed near the probes on the walls. In contrast to ref. 1, one of the antiprobes is used as the reference electrode and is held at a constant potential relative to the plasma during the measurements. For the purposes of calculation the plasma potential is taken as the value at which the second derivative of the probe current passes through zero.

Figure 1 gives distribution functions for three positions of the movable probe. When a magnetic field is applied the fraction of fast electrons in the center of the tube is decreased sharply; however, there is very little change at the periphery. It is noted that the radial distribution of the total electron density is approximation by a Bessel function. Similar results are obtained at a pressure of 0.2 torr with an interelectrode distance of 35 cm.

The measured distribution functions are used to calculate the number of ionization events per electron per unit time z(r). The following equation is used:

$$z(r)=\frac{\sqrt{\frac{2e}{m}}\int\limits_{V_i}^{\infty} Q_i(V)\sqrt{V}F(r,V)\,dV}{\int\limits_0^{\infty} F(rV)\,dV}, \qquad (1)$$

TABLE 1

H, Oe	r/R	$n\cdot 10^{-9}$, cm^{-3}	$z\cdot 10^{-4}$, sec^{-1}	$z_1\cdot 10^{-4}$, sec^{-1}	$z_T\cdot 10^{-4}$, sec^{-1}

	0.8	1.9	2.3		

where F(r, V) is the measured distribution function, $Q_i(V)$ and V_i are the ionization cross section and ionization potential, and e and m are the charge and mass of an electron. The cross section for direct ionization $Q_i(V)$ is taken from ref. 3. Since the distribution function with the field present depends on the distance from the axis r, the quantity z is a function of r, in contrast to the Schottky theory, where it is assumed to be constant.

An estimate of the importance of stepwise ionization[1] made on the basis of the population of resonance and metastable levels measured by the reabsorption method[5] has shown that this process leads to an ionization rate at least an order of magnitude smaller than that for direct ionization.

Knowing z(r) and the radial variation of the total density n(r) we can determine the average ionization rate over the cross section from the equation

$$z_1=\frac{\int\limits_R^0 z(r)\,n(r)\,r\,dr}{\int\limits_0^R n(r)\,r\,dr}, \qquad (2)$$

where R is the tube radius.

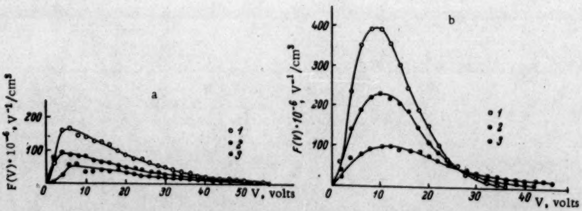

Fig. 1. Electron energy distribution functions at various distances from the axis of the discharge tube. p = 0.05 torr, L = 20 cm. Values of r/R: 1) 0; 2) 0.4; 3) 0.8. H in oersteds: a) 0; b) 420.

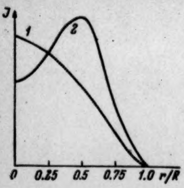

Fig. 2. Radial distribution of the relative radiation intensity. λ = 5016 Å. Values of H in oersteds: 1) 0; 2) 420.

An average ionization rate z_2 can also be determined from the value of the ion current density to the wall j if we assume that the recombination of charged particles occurs at the walls of the tube; we use the equation

$$z_2 = \frac{Rj}{e\int\limits_0^R n(r)\,r\,dr}. \tag{3}$$

Values for z_1 and z_2 are given in Table 1 and are in close agreement under all conditions. Evidently, z is essentially constant in the absence of a magnetic field over the whole of the cross section. With the magnetic field, z increases sharply with r. Although the value of z near the axis drops markedly when the magnetic field is applied, the value near the periphery changes very little. The measured radial distribution of radiation intensity of certain spectral lines confirms qualitatively the radial variation of the distribution functions (Fig. 2). The change in the electron distribution function with radius must be taken into account in any calculation of the average ionization rate over a cross section.

The relation between the radial variation in the electron distribution function in a magnetic field and the so-called anomalous diffusion in a high-frequency discharge[6] requires special examination.

Line shape of a quadrupole mass spectrometer

G. I. Slobodenyuk

(Submitted January 15, 1973; resubmitted June 20, 1973)
Zh. Tekh. Fiz., 44, 470-472 (February 1974)

The shape and intensity of a line in the mass spectrum of a quadrupole mass spectrometer have been studied as functions of the energy of the ions injected into the analyzer, V_{acc}, and as functions of the ratio of the voltages in the analyzer, $U/V = \lambda$. A criterion for evaluating the overall quality of the detector is proposed and a simple method is described for determining the resolving power of the spectrometer.

This experimental study has been carried out because of the importance of the characteristics of a quadrupole mass spectrometer, the difficulties involved in an exact analytic description of them, and the absence of information on this question in the literature (there are only a few fragmentary reports[1-4]).

The experiments are carried out on the KM-2 apparatus, which is part of the KM-4 gas analyzer.[5] The lines of molecular oxygen $^{16}O_2^+$ (M = 32 amu) and the xenon isotope $^{134}Xe^+$, which are isolated in the mass spectrum, are monitored. These lines appear in the mass spectrum when air and pure xenon, respectively, are injected at a pressure of $(3\text{-}4) \cdot 10^{-6}$ torr into the working chamber of the gas analyzer, evacuated beforehand to a pressure of 2 10^{-7} torr. The signal is recorded at the minimum scanning rate in the KM-2 (0.15 amu/sec) and at the maximum feed rate for the chart of an ÉPP-09MZ recording potentiometer. All the information with which we are concerned here is shown in Figs. 1 and 2: the variations in the shape and intensity of a line in the mass spectrum of the KM-2 corresponding to a change in the energy of the ions injected into the analyzer (V_{acc}, V) and a change in the ratio of the analyzer voltages (λ, arbitrary units), respectively. These figures show two series of recordings of the molecular oxygen line correspondihg to the specified operating conditions of the quadrupole mass spectrometer. The quantitative changes in the line intensities can be determined on the basis of the line amplitudes and the scaling factors indicated in the figures.

We can reach certain conclusions on the basis of these figures. 1) As V_{acc} is reduced and λ increased, the corresponding increase in the absolute resolution of the quadrupole mass spectrometer at the 50% level is accompanied by an extremely nonuniform decrease in the line intensity. Initially, this decrease is not very pronounced (see the first nine peaks at the left in Fig. 1 and the first 11 peaks in Fig. 2), but then the decrease becomes important, amounting to a factor of tens or hundreds. 2) In both cases, as the resolution increases the line changes from a dome shape (in agreement with the results of ref. 3) to a bell shape with large tails. It is found in observation of the change in the line shape at various pressures in the detector of the spectrometer that these tails are due not only to the factors discussed in ref. 4, but also, and significantly, to scattering of " unstable"[1,4] ions by the residual gas molecules at the end of the analyzer. This scattering helps the ions reach the ion detector. 3) There is a characteristic distortion of the peak shape (indicated by the arrows in Figs. 1 and 2) caused by distortions of the analyzer field and leading to a parasitic peak broadening. All these variations in the shape and intensity of the $^{16}O_2^+$ peak are reproduced in the behavior of the $^{134}Xe^+$ peak.

Comparing the results, we conclude that there is an optimum adjustment for the resolution of the spectrometer, i.e., for minimizing possible changes in sensitivity. The method consists essentially of simultaneously changing two quantities, V_{acc} and λ, in accordance with an equation which can be derived in an elementary manner from the equations for the absolute resolution, which follow from the theory of quadrupole mass spectrometers: $U_{acc} = 0.089(Mf^2L^2/A^{2/3})(1-\lambda/0.16784)$, where M is the ion mass

The arrows show characteristic distortions. I) 1:1, 1; II) 1:1, 2; III) 1:1, 3; IV) 1:1, 4; V) 1:1, 5; VI) 1:1, 5.5; VII) 1:1, 6; VIII) 1:1, 6.76; IX) 1:1.57, 6.76; X) 1:1.57, 7; XI) 1:0.46, 7.5; XII) 1:0.46, 7.5; XIII) 1:0.46, 8.0; XIV) 1 :0.2, 8.0; XV) 1:0.2, 8.5; XVI) 1:0.06, 8.5; XVII) 1:0.06, 9.0; XVIII) 1:0.06, 9.5; XIX) 1:0.023, 9.5; XX) 1:0.023, 10; XXI) 1:0.023, 10.5; XXII) 1:0.0004, 11.00. (The $^{14}N_2^+$ peak.)

(amu), f is the frequency (megahertz) of the rf voltage in the analyzer, L is the length of the analyzer (centimeters), and A is the ratio of the peak amplitude to the signal level at which the resolution is required.

A second conclusion is that we can evaluate the nature and, sometimes, the magnitude of the imperfections in the field configuration in the analyzer on the basis of the characteristic distortions which these imperfections cause in the peak shape. Furthermore, the minimum value of U_{acc} at which it is still possible to obtain the mass-spectrum signal if the relation given above between U_{acc} and λ is satisfied is an objective measure of the imperfections of the analyzer and the ion source. This minimum value can thus serve as a criterion for evaluating the production quality of the detector in a quadrupole mass spectrometer or as a criterion for the cleanliness of the field-shaping electrodes; contamination of these electrodes also distorts the field configuration in the analyzer and the ion source.

When the KM-2 is adjusted in the optimum manner, stable operation is possible with the following set of basic parameters: At an absolute resolution of 0.5 amu at the 50% level at a mass of 219 amu and at a recording rate of 0.4 amu/sec, a sensitivity of $2 \cdot 10^{-12}$ torr nitrogen equivalent is obtained. The dynamic range of the apparatus is[4] $2.6 \cdot 10^5$, and the isotopic sensitivity is 10^4 at 18 and 19 amu. The maximum working pressure in the detector is $1.5 \cdot 10^{-4}$ torr.

In the course of our experiments we have found and successfully used a simple method for achieving an operational relative quantitative evaluation of the signal discrimination of the quadrupole mass analyzer in the mass range being analyzed. This method consists essentially of recording the mass spectrum at a low resolution, with a low signal discrimination and an approximately unit signal-suppression factor. Then, with the apparatus operating normally, the spectrum is recorded at the required resolution. The changes in the intensity ratios for lines of different masses in the two spectra yield the (normalized) desired functional dependence of the discrimination (or suppression) factor on the mass number in the mass range being analyzed. To determine the mass discrimination in the KM-2, we record the spectra of singly, doubly, and triply charged xenon at relative mass resolutions of 70 and 500 at a mass of 134 amu. The ratios of the peak intensities $^{132}Xe^{+++}$:$^{132}Xe^{++}$:$^{132}Xe^{+}$ are 1:4.8:13.4 in the first case and 1:1.44:0.3 in the second. From these ratios we find the discrimination factors at masses of 44, 66, and 132 amu, referred to the signal at 44 amu, to be 1:0.3:0.022.

Investigating prebreakdown fields in water by means of the Kerr effect

I. T. Ovchinnikov, K. V. Yanshin, and É. V. Yanshin

Institute of Automation and Electrometry, Siberian Branch,
Academy of Sciences of the USSR
Siberian Scientific-Research Power Institute, Novosibirsk

(Submitted February 21, 1973)
Zh. Tekh. Fiz., 44, 472-474 (February 1974)

The electric field distribution in the gap formed by extended electrodes is investigated in fields of 1.3 MV/cm. Space charge, which can distort the field in the gap, is not formed for 200 nsec (measurement error of 0.3%).

The electric field distribution in the discharge gap is of considerable importance in the theory of breakdown and in the development of methods of controlling electrical discharges indielectrics. From this point of view water is of interest because it is a good example of a polar liquid; in addition, it finds many applications in high-voltage electrical devices, such as pulsed energy storage units, switches, etc.

We have studied the field distribution in a Kerr cell formed by cylindrical brass electrodes (diameter 1 cm, length 5 cm, and gap 0.2 cm), filled with distilled water.[1)]

The light from an ISSh-400 flash tube is passed through a collimating device, a filter, a piece of polaroid P_1, to the cell, and is analyzed by means of the polaroid P_2. The transmitted light is recorded by sweeping the slit of a "Kanal" high-speed electrooptical photorecorder.[1]

The light intensity incident on the photocathode of the recorder is

$$I = I_0 \sin^2 \pi B l E^2,$$

where $B \sim 10^{-11}$ cm/V^2 is the Kerr constant of water,[2] and l is the optical path length in the field E. As the voltage across the cell electrodes is increased, alternate illumination and darkening of the gap occurs and a series of alternate dark and bright bands are recorded on the photosweep. If the field across the observed volume is uniform, the bands will be straight lines perpendicular to the time axis of the chronogram. Any deviation of the field from uniformity will give rise to a corresponding bending of the bands.

On the part of the chronogram (see Fig. 1) corresponding to the flat part of the pulse ($50 < t < 200$ nsec) there are four pairs of straight bands, i.e., the field in the gap is uniform. The appearance of these bands is due to the small change in the voltage across the cell. In our case, for a pulse amplitude U = 265 kV and a corresponding field $E \sim 1.3$ MV/cm, a change in the field of 0.3% gives rise to the appearance of a single additional band.

The limited resolution time, determined mainly by the slit width, enables us to record only the first pair of bands on the leading edge of the pulse ($0 < t < 50$ nsec). During this time the total number is approximately 75 pairs. The interval between the dark and bright bands for the first pair is approximately 5 nsec, and 0.1 nsec for the last pair.

The symmetric broadening of the dark bands at the

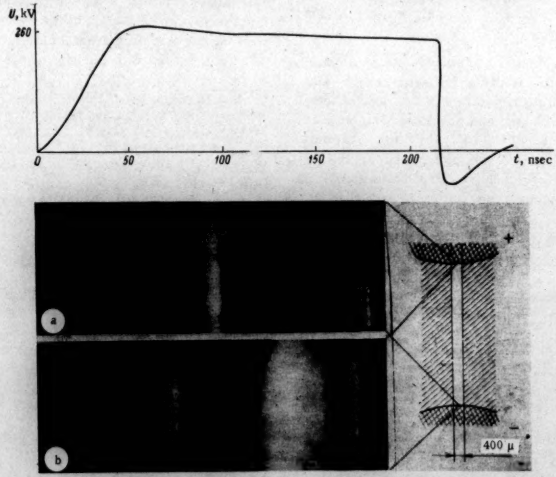

Fig. 1. Slit sweeps of the light modulated by the Kerr cell, combined with an oscillogram of the applied pulse. a) Polaroids crossed; b) polaroids uncrossed. The position of the slit with respect to the cell electrodes is shown on the right.

edges is due to current overload of the electrooptical converter. This can be seen by comparing the photosweeps, where, when the orientation of a polaroid is changed, the bands corresponding to the same voltage change their direction of curvature, while the bright bands are always convex.

Hence, from the photosweeps obtained it follows that for a field of E ~ 1.3 MV/cm the field in the gap remains uniform to at least 0.3% for 200 nsec. This shows, in particular, the untenability of the hypothesis which explains the "polarity effect" (the predominant development of the discharge from the anode in water when pulses of length $\leq 10^{-6}$ sec act) as due to the formation of a space charge, resulting from the emission of electrons from the cathode into the interelectrode gap, which increases the field in the region of the anode[3-5] by more than a factor of 1.5. Hence additional difficulties arise in explaining the electric breakdown of water from the point of view of ionization theory.

The authors thank Yu. N. Vershinin for suggesting the problem and for his interest.

---

1) The parameters of the cell and of the high-voltage pulse are chosen to provide a field ≥ 1 MV/cm in the gap; at the same time breakdown is controlled by limiting the pulse length.

New method for obtaining probe characteristics

Yu. I. Osipov

P. N. Lebedev Physics Institute
Academy of Sciences of the USSR, Moscow
(Submitted December 8, 1972)
Zh. Tekh. Fiz., 44, 474-477 (February 1974)

A new method is proposed for obtaining probe characteristics. This method avoids the difficulties which arise in studying plasmas with high particle densities and high energy densities.

1. In the usual method of obtaining the probe characteristic (Fig. 1a), an external (adjustable) voltage source is connected between the probe and a reference electrode.[1] The power of this source must exceed the power evolved in the external probe circuit in the flow of the saturation electron current I_{e0}, which is proportional to the probe area and the electron density n_e. For example, in the plasma of an Ar^+ laser we have $n_e \sim 10^{13}$–10^{14} cm^{-3}, and for a probe 1 mm long and 0.1 mm in diameter the current I_p can reach 1.0 A or more. Estimates show that in this case the power capacity of an external voltage source suitable for the measurements is hundreds or thousands of watts. Serious technical difficulties arise in designing such voltage sources. Sometimes a charged high-capacitance capacitor bank is used, and the probe characteristic is recorded point by point (with each point corresponding to a certain bank voltage). This method, which requires much time, can be used if the plasma is stable enough over the time required to obtain the entire characteristic.

In this note we propose a new pulsed method for obtaining probe characteristics; we have used this method successfully to study the plasma in a cw Ar^+ laser. The method is based on the circumstance that the probe current is a function only of the probe potential with respect to the plasma; in other words, the shape of the probe characteristic is not a function of the parameters of the external part of the probe circuit and is governed solely by processes which occur in the plasma itself and at the electrodes. This statement is true if the time required to record the characteristic, τ, is short in comparison with any characteristic time for changes in the plasma properties, τ_1, but large in comparison with the time required for a redistribution of the ions in the sheath, τ_2. This latter time is approximately equal to the ratio of the Debye length λ_D to the ion thermal velocity v_+, and for the plasma of an Ar^+ laser it is $(10^{-3}\ \mathrm{cm})/(10^5\ \mathrm{cm/sec}) = 10^{-8}$ sec.

If an RC circuit is connected between the probe and the reference electrode (e.g., the anode) (Fig. 1b), the situation is equivalent to that which would obtain if we connect to the RC circuit an emf $U_f = V_f - V_a$ (Fig. 1a). A transient process begins in the circuit: A current I_p flows and charges capacitance C. The voltage between the probe and the anode, U(t), which is equal to the sum of the voltage across the capacitance, $U_C(t)$, and that across the resistance, $U_R(t)$, increases from some initial value $U_{ini} = V_{ini} - V_a$ to $U_f = V_f - V_a$ ($U_{ini} = RI_{ini}$). The probe potential assumes all values from V_{ini} to the floating potential V_f. (If R = 0, we have $V_{ini} = V_a$; if $R \to \infty$, we have $V_{ini} \to V_f$; Fig. 1a.)

If the voltage $U_R(t) = RI_p(t)$ is fed to the Y plates of an oscilloscope and the voltage $U(t) = U_C(t) + U_R(t)$ to the X plates, the electron branch of the probe characteristic is produced on the oscilloscope screen. The values of R and C only govern the recording time and the initial potential V_{ini} from which the recording of the electron branch of the characteristic begins.

If the cathode is used as a reference electrode, the ion branch of the probe characteristic is obtained in a completely analogous manner. In this case the probe potential assumes all values from $\sim V_k$ to V_f. The RC circuit can be replaced by an RL or an RCL circuit.

This method has the following advantages: 1) There is no external voltage source in the probe circuit; 2) it is extremely simple; 3) the parameters of the external circuit are independent of the electron density and other plasma properties; 4) this arrangement can be used to study a variety of steady-state, transient, and pulsed

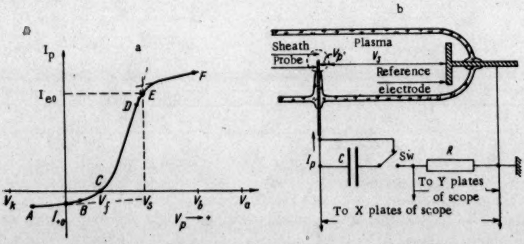

Fig. 1. a) Typical probe (voltage–current) characteristic. V_k is the cathode potential, V_f is the floating potential, V_s is the space potential, V_b is the breakdown potential at the probe, V_a is the anode potential, I_p is the probe current, and I_{e0} and I_{f0} are the electron and ion saturation currents, respectively; b) schematic diagram of the new method for obtaining a single-probe characteristic.

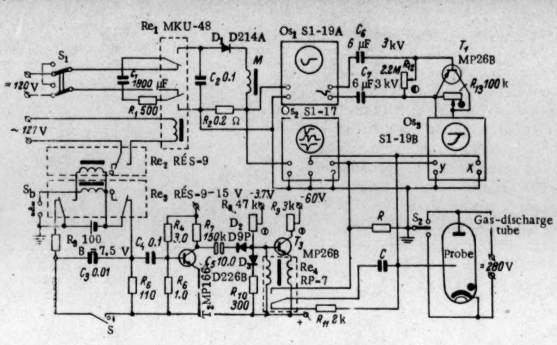

Fig. 2. Schematic diagram of the electronics.

plasmas, because the recording time can be easily adjusted over a broad range by changing the values of R and C. This method thus simplifies and extends the range of applicability of the probe method. It is only necessary to satisfy two conditions, which are standard for the single-probe method: 1) There must be a suitable reference electrode; 2) the recording time τ must satisfy the condition $\tau_2 \ll \tau \ll \tau_1$ stated above.

2. Another difficulty arises from the circumstance that in plasmas with a high energy density and a high particle density (in this case I_{e0} is also high) there is the danger that the probe will be destroyed. Estimates for an Ar^+ laser (energy density of 200-700 W/cm^3) show that the probe cannot be left in the plasma safely at the floating potential for more than 0.1 sec, and the time over which the characteristic is recorded cannot exceed 1 msec. It is therefore necessary to use a moving probe[2] and a pulsed method to record the characteristic. In our setup a "jumping" probe is thrust directly upward by an electromagnet (M) for 20-40 msec. It penetrates a specified distance into the plasma and hovers at its uppermost point for 200-500 μsec while the probe characteristic is recorded. Then it falls freely back to its initial position in ~ 80 msec. The maximum probe displacement during the measurement (account is taken of the elastic impact with the ring, which limits its motion) does not exceed 0.1 mm. The probe remains in the discharge plasma for about 35 msec. Figure 2 shows the complete circuit for controlling and synchronizing the probe motion and recording the probe characteristics. When the button switch (S_b) is pushed (the cable release for a camera is used), capacitance C_1 (1800 μF), charged to 120 V, discharges through the electromagnet (M), in which the ring with the probe and contacts (K) are held in a quartz tube. When the probe reaches its uppermost position and closes the contacts, a small capacitance C_3 (previously charged by battery B) discharges completely through resistance R_5. This arrangement prevents arcing between contacts K when they subsequently are opened. The voltage pulse across resistance R_5 triggers a blocking generator, whose transformer is the winding of relay RP-7, which closes the RC circuit. When this method is used to actuate relay RP-7, the delay between the closing of the contacts (K) and the closing of the RC circuit does not exceed 0.5 msec. The probe characteristic is recorded by an oscilloscope (Os_3: an S1-19B oscilloscope with two BPU-1 units). The current $I_p(t)$ and the potential U(t) are recorded, along with the magnet (M) current, by oscilloscope Os_2 (S1-17). Since the RC circuit is open as the probe is rising, and capacitance C is shorted, the U(t) behavior gives the radial profile of the floating potential. To eliminate a perturbing effect on the plasma by the field of magnet M, and to turn this magnet off before the recording of the probe characteristic is begun, we use a diode (D_1) and adjust the relative positions of magnet M and the ring with the probe. This adjustment is monitored on oscilloscope Os_2. Oscilloscope Os_1 (S1-19) is used as a pulse generator and to indicate the time over which the beam of oscilloscope Os_3 is intensified. The beam is intensified by a pulsed shunting of variable resistance R_{13} by a transistor (T_1); this resistance regulates the beam brightness of the S1-19 oscilloscope. In this manner we can adjust the beam brightness from zero to maximum and thus work at shorter recording times. Oscilloscopes Os_1 and Os_2 are

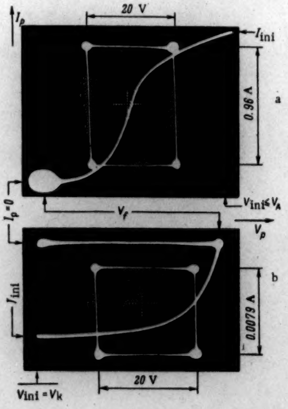

Fig. 3. Oscillograms of the probe characteristic obtained by this method. a) Electron branch; b) ion branch. The horizontal line at the top shows the change in the floating potential as the probe moves through the plasma. The scale rectangles are produced by briefly feeding calibrated periodic rectangular voltages from two generators to both pairs of oscilloscope plates (while the probe is rising).

triggered by the leading edge of the current pulse in magnet M. Switch S_2 is used to switch from the mode in which the electron branch of the characteristic is recorded to that in which the ion branch is recorded. Relays Re_1, Re_2, and Re_3 are used because it is necessary to hold part of the circuit at the floating potential during the measurement and to avoid a double grounding. As an example, Fig. 3 shows oscillograms of both branches of the probe characteristic, obtained with this apparatus in the plasma of an Ar^+ laser. The construction of the probe unit and the results of measurements in the plasma of an Ar^+ laser will be published separately.

In conclusion the author thanks N. N. Sobolev, V. F. Kitaeva, and A. A. Sapronov for their interest; the author is indebted to A. L. Shelekhov and V. P. Ageev for their participation in this work.

Condensation of an erosion plasma

B. A. Osadin and N. V. Rusakov

(Submitted December 12, 1972)
Zh. Tekh. Fiz., 44, 477-478 (February 1974)

The experimental use of a plasma gun as a pulsed evaporator for depositing thin films in vacuum is reported. The condensation rate is found to be 10^6-10^8 Å/sec, or five to six orders of magnitude higher than the condensation rate obtained with standard methods for obtaining thin films. Under certain conditions a brightly glowing plasma sheath is observed directly in front of the condensation surface. This sheath results from the difference of the condensation coefficient from unity. Other unusual features of the physical conditions for the condensation of an erosion plasma are reported.

1. Over the last two decades there has been an intense study of devices that generate pulsed plasma flows, particularly generators of an erosion plasma, i.e., the plasma produced in a vacuum discharge as a result of the destruction of the electrodes or of dielectric inserts.[1] Various applications have been found for erosion-plasma generators (in spectroscopy, in physical studies of cool plasmas, propulsion, etc.), but there has been essentially no use of these generators in applications associated with condensation of erosion-plasma streams. We believe that the study of this condensation can be very worthwhile both for studying the physics of the condensation process and in techniques for producing thin films, which are widely used in modern electronics.[2]

2. We have carried out an experimental study of the condensation of sulfur vapor produced with a plasma gun whose design and basic characteristics are described elsewhere.[3] The only changes in the experimental apparatus are in the method used to initiate the discharge, which is initiated by a high-voltage pulse (~ 40 kV) and the subsequent discharge of an auxiliary capacitor (2 μF, 500 V) in the electrode material (molybdenum) and in the material of the auxiliary insulator (alundum), chosen in order to reduce the corresponding impurity levels in the plasma.

The condensation occurs on flat substrate plates (glass or copper) at various distances from gun and at various angles with respect to its axis.

In addition to carrying out the measurements which are standard for plasma guns (recording oscillograms of the discharge currents, measuring the sulfur expenditure per discharge as a function of the voltage on the capacitor bank, and taking streak photographs of the plasma glow), we use traps 25 mm in diameter and 40 mm long, made of stainless steel foil, to study the angular distribution of the mass emission (Fig. 1). We study the sulfur films produced on a substrate in one or several discharges under an MIM-7 microscope; we determine the thickness of these films by weighing them and with an MII-4 interferometer.

3. In our experiments the condensation conditions are markedly different from the ordinary condensation conditions for the case in which thin films are deposited in vacuum by means of various types of evaporators.[4,5] In our experiments we are dealing with the condensation of a gas-dynamic flow, in which the mean free path of the vapor particles is less than or much less than the distance from gun (evaporator) to the substrate ($\lambda \ll d$). The density of sulfur atoms in the incident flow is 10^{14}-10^{16} cm^{-3}, depending on the discharge energy and the distance d, and the deposition rate of the condensate is 10^6-10^8 Å/sec, i.e., five or six orders of magnitude higher than the typical deposition rates achieved with steady-state evaporators. The flow velocities of (4-7) · 10^5 cm/sec and the high ethalpy of the plasma produce heat fluxes of 10^4-10^5 W/cm^2 to the substrate, so that during the condensation various layers of the condensate are at quite different temperatures, and these temperatures vary as a function of the time. At a heat flux larger than or roughly equal to 3 · 10^5 W/cm^2 we observe reevaporation of the condensate and even destruction of the copper substrate.

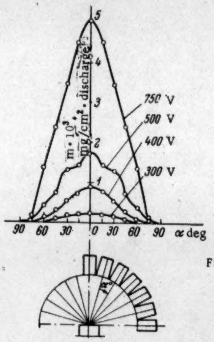

Fig. 1. Angular distribution of the mass emission. C = 280 μF.

4. With d ≤ 10 cm, a brightly glowing plasma "cushion" is observed near the substrate surface (Fig. 2). The formation of this plasma can be attributed to the reverse flow of vapor from the substrate, which results from incomplete condensation or reevaporation from the substrate. Calculations of the thermal conditions and comparison of the streak photographs for the glass and copper substrates show that the presence of elastically or diffusely reflected particles can be assumed primarily responsible for the formation of the plasma cushion. Photometry of the streak photographs reveals that the brightest part of the cushion is about 0.3-0.4 mm from the substrate, (~ λ). Accordingly, in these experiments the erosion plasma condenses from a plasma sheath at (2-4) · 10^4 °K directly adjacent to the substrate. Here again there is a difference from the condensation conditions in ordinary methods for producing thin films in vacuum.

5. We produce sulfur films ranging in thickness from several hundred to several thousand angstroms (the thickness increment varies from tens to hundreds of angstroms per discharge). Measurements of the film thickness reveal that films quite uniform with respect to thickness can be produced at a moderate discharge energy (W < 35 J),

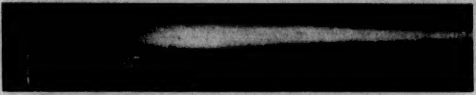

Fig. 2. Streak photograph of the plasma glow at the substrate (the vertical scale is 5:1, while the horizontal scale is 5 mm = 1 μsec).

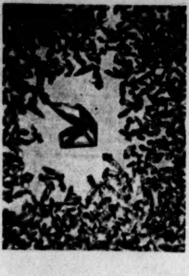

Fig. 3. Photograph of part of the film after it was held for 48 h in air (×600).

in good agreement with Fig. 1. Inspection of the films immediately after their production under a microscope at ×600 reveals no defects or foreign inclusions. After the films are held for 60 h in air, they crystallize (Fig. 3). First, individual crystals form at inhomogeneities of the substrate; then the crystallization spreads over the entire surface. The large crystals break up into smaller crystals, and the film becomes polycrystalline. Relative thin films retain their initial appearance relatively longer.

Theoretical and mathematical physics

Energy resolution of quadrupole lenses for charged-particle beams

V. S. Siksin

(Submitted May 3, 1973; resubmitted July 16, 1973)
Zh. Tekh. Fiz., 44, 481-490 (March 1974)

The energy resolution of a system consisting of a 90° deflecting magnet and a doublet of quadrupole lenses is found for arbitrary values of the field parameters of the individual lenses of the doublet. In three-dimensional (k_1, k_2, F) space the energy resolution function F(k_1, k_2) is represented by a surface. Cross sections of this energy resolution surface made by planes perpendicular to the plane of its base (k_1, k_2) which pass through the origin form a family of characteristic curves with maxima. The values of the energy resolution are the same at these maxima, being equal to the energy resolution of the beam produced by the deflecting magnet alone. It is established that the necessary and sufficient condition for the preservation and reproduction of a chosen energy resolution curve of the beam, and thus the preservation and reproduction of the value of the energy resolution for a change in the field parameters k_1 and k_2 of the individual lenses of the doublet, is the preservation of a constant value of k_1/k_2 equal to 1.02, 2.05, and 0.51, and cases "c" and "d" have been determined. The value of the energy resolution of a beam of protons in the regions of transition from a virtual to a real image of the object (beam crossover) for various values of k_1/k_2 does not depend on C, the distance from the exit lens of the doublet to the crossover plane, at which the energy resolution is determined. For k_1/k_2 equal to 1.02, 2.05, and 0.51, various distances C, and cases c and d differences are found in the effect of variations of the parameters k_1 and k_2 on the energy resolution. The energy resolution curves are compared for these cases. The values of the parameters $k_{1\max}$ and $k_{2\max}$ corresponding to the beat value of the energy resolution are determined. The widths of these curves are found.

INTRODUCTION

The general considerations for energy resolution of a beam of charged particles in a system consisting of a 90° deflecting magnet and a doublet of quadrupole lenses are given in ref. 1. Those principles are applicable to nonrelativistic and relativistic particles. These principles are illustrated in ref. 1 for the case of identical values of the field parameters of the individual lenses of the doublet of quadrupole lenses. In the present note we discuss the energy resolution of a beam of charged particles by a 90° deflecting magnet and a doublet of quadrupole lenses for arbitrary values of the field parameters k_1 and k_2 of the individual lenses of the doublet.

PRINCIPLES OF THE ENERGY RESOLUTION OF A BEAM OF CHARGED PARTICLES FOR ARBITRARY VALUES OF THE FIELD PARAMETERS OF THE INDIVIDUAL LENSES OF A DOUBLET OF QUADRUPOLE LENSES

We consider the transmission of a beam of charged particles through a system consisting of a 90° deflecting magnet and a doublet of quadrupole lenses. The energy resolution in the plane perpendicular to the axis of the beam and at a distance C from the last lens of the doublet is given by[1]

$$F=\pm\frac{\Delta E}{E}=\frac{2\Delta x}{\left(2r_0+\frac{B}{X}-\frac{C}{X}\right)}\quad\text{for}\quad\frac{B}{X}\geqslant\frac{C}{X},\qquad(1a)$$

$$F=\pm\frac{\Delta E}{E}=\frac{2\Delta x}{\left(2r_0+\frac{C}{X}-\frac{B}{X}\right)}\quad\text{for}\quad\frac{B}{X}<\frac{C}{X},\qquad(1b)$$

where $\Delta x = \pm\ 0.05$ cm is the deviation of the beam from the axis a distance C from the right-hand edge of the last lens of the doublet, and all the terms of the sum in the denominators of (1a) and (1b) are measured in centimeters. The quantity B is the distance from the right-hand edge of the exit lens of the doublet to the image of the object, the beam crossover, located at the focus of the magnetic analyzer. The quantity X is the magnification of the doublet of quadrupole lenses. The quantity $2r_0$ is twice the radius of deflection of the beam in the analyzing magnet. Equation (1a) holds if $B/X \geq C/X$. This condition corresponds to the formation of a virtual or a real image of the object (beam crossover) and to finding a real image either in the plane in which the energy resolution of the beam is determined, or in planes to the right of it in the direction of the beam axis. Equation (1b) holds if $B/X < C/X$. In this case a real image of the object is formed; the beam crossover lies between the right-hand edge of the exit lens and the plane in which the energy resolution is determined. All the quantities B, C, and X are positive. Equations (1a) and (1b) are applicable to nonrelativistic and relativistic particles.

There are two ways of arranging the individual lenses of the doublet. In the first case "c" in the plane in which the proton momenta are dispersed the beam diverges in the first lens of the doublet and converges in the second. In the second case "d" in the same plane of dispersion of the magnet the beam converges in the first lens and diverges in the second. We denote the field parameters of the first lens of the doublet by k_1 and the second by k_2. The ion-optical quantities B_c, B_d, X_c, X_d, B_c/X_c, B_d/X_d, C/X_c, and C/X_d, and the energy resolution of the beam F have been calculated by computer using the equations given in ref. 1. From these calculations the function F(k_1, k_2) is found. Each of the equations (1a) and (1b) relating the quantities F, k_1, and k_2 is the equation of a surface. The function F(k_1, k_2) calculated for cases c and d and distances C = 100 and 800 cm is shown in Figs. 1a, 2a, 1b, and 2b. The function F(k_1, k_2) has also been calculated for cases c and d and distances C = 200, 314, 506, and 700 cm. For each distance C it is represented by a complicated surface in three-dimensional F, k_1, k_2 space. Cross sections of this surface of energy resolutions made by planes perpendicular to its base (k_1, k_2) and passing through the origin form characteristic curves with maxima. The energy resolution of the beam is the same at these maxima, being equal to the energy resolution of the beam produced by the deflecting magnet alone (10^{-3}).

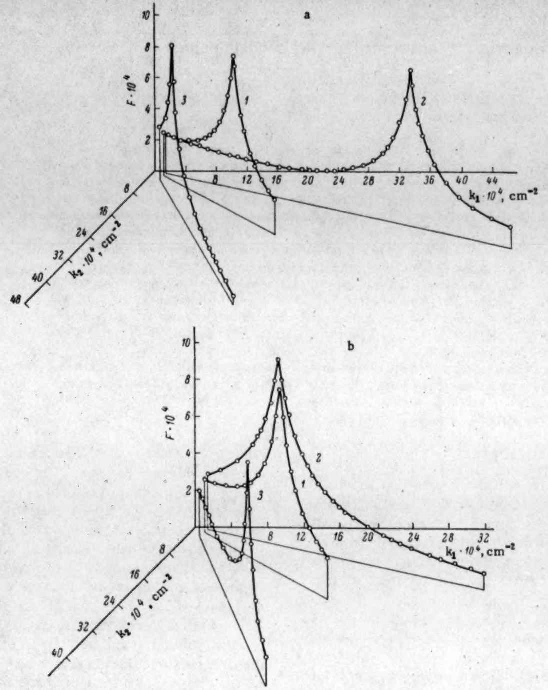

Fig. 1. Energy resolution surfaces of a beam of protons for lens arrangement c (a) and d (b). Distance C = 100 cm. Curves 1, 2, and 3 correspond to k_1/k_2 equal to 1.02, 205, and 0.51 respectively.

In these figures, curve 1 corresponds to essentially identical values of the field parameters $k_1 \approx k_2$ ($k_1/k_2 = 1.02$). Curve 2 corresponds to the ratio $k_1/k_2 = 2.05$, and curve 3 holds for $k_1/k_2 = 0.51$. Segments of the energy resolution curves of the beam 4-14 correspond to values of k_1/k_2 equal to 1.2, 0.87, 0.75, 0.83, 0.9, 0.92, 1.09, 1.11, 1.14, 1.33, and 1.45. The figures also show the projections of the energy resolution curves on the (k_1, k_2) plane. It is clear from Figs. 1 and 2 that the energy resolution surfaces are different for cases c and d. In case d the values of the parameters $k_{1\,\max}$ and $k_{2\,\max}$ corresponding to the maxima of the various energy resolution curves 1, 2, 3 lie closer to one another than in case c. In addition, when the lenses of the doublet are interchanged curves 2 and 3 are reversed.

If, in an attempt to focus the beam, the field parameters k_1 and k_2 of the individual lenses are changed separately and the ratio k_1/k_2 is not kept constant, there will be a jump from one energy resolution curve to another with irregular changes in the energy resolution of the beam. Consequently, an examination of the energy resolution surfaces leads to an important condition: the theorem on the preservation and reproduction of the value of the energy resolution of the beam in focusing by a doublet of quadrupole lenses.

A necessary and sufficient condition for keeping a given energy resolution curve and thus keeping a given energy resolution with changes in the field parameters k_1 and k_2 is that the ratio k_1/k_2 must be kept constant.

COMPARISON OF ENERGY RESOLUTION CURVES CALCULATED FOR CERTAIN VALUES OF k_1/k_2 AND VARIOUS DISTANCES C

Figures 3 and 4 show curves 1, 2, and 3 previously represented in three-dimensional F, k_1, k_2 space. As in the case of identical values of the field parameters $k_1 \approx k_2$, these curves show that there are only two possibilities for obtaining high energy resolution of a beam of protons. One way is to operate the doublet of quadrupole lenses in the weak defocusing regime, i.e., on the left-hand slopes of the curves. The second way is to operate in the strong focusing regime, i.e., on right-hand slopes of the curves.

Table 1 shows some calculated values of the energy resolutions for C = 800 cm.

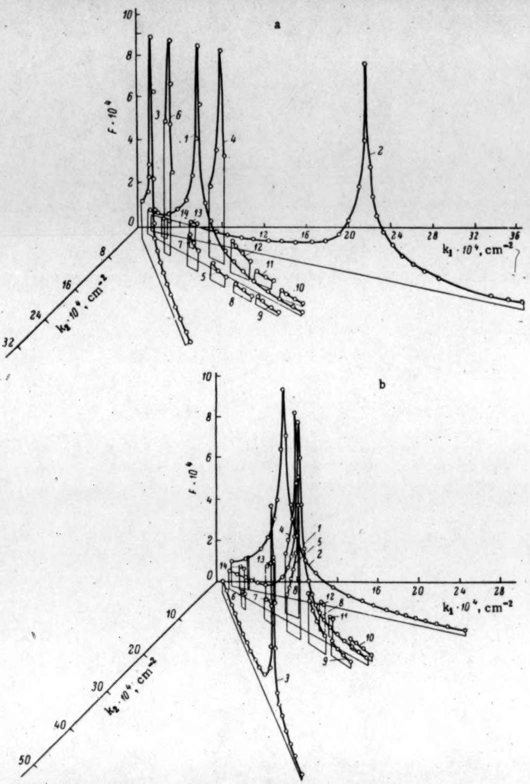

Fig. 2. Energy resolution surfaces of a beam of protons for case c(a) and for case d (b). Distance C = 800 cm. Curves 1, 2, and 3 are calculated for k_1/k_2 equal to 1.02, 2.05, and 0.51. Fragments of curves 4-14 were obtained for k_1/k_2 equal to 1.02, 0.87, 0.75, 0.83, 0.9, 0.92, 1.02, 1.11, 1.14, 1.33, and 1.45.

TABLE 1. Comparison of Energy Resolutions of a Beam of Protons

Case	$k_1 \cdot 10^4$, cm^{-2}	k_1/k_2	$F \cdot 10^4$
c	1.86	0.51	2.05
c	1.86	1.02	1.04
c	1.86	2.05	0.829
c	23.6	2.05	1.98
c	23.6	1.02	0.2
c	60	2.05	0.082
c	23.6	0.51	0.086

d	24.6	1.02	0.306
d	24.6	2.05	0.303
d	29.5	0.51	0.13
d	29.5	2.05	0.202

Table 2 gives values of the field parameters of the first lens of the doublet $k_{1\max}^{(1)}$, $k_{1\max}^{(2)}$, and $k_{1\max}^{(3)}$ obtained from curves 1, 2, and 3 of Figs. 3a and 4a and similar curves for distances C = 200, 314, 506, and 700 cm and corresponding curves for case c, in which the last lens of the doublet is a converging lens. The superscripts (1), (2), and (3) refer to the energy resolution curves with k_1/k_2 equal to 1.02, 2.05, and 0.51 respectively. These values of the field parameters correspond to the maximum value of the energy resolution of a beam of charged particles (10^{-3}), which depends only on the dispersion of the magnet. The values of $\Delta k_1^{(1)}$, $\Delta k_1^{(2)}$, and $\Delta k_1^{(3)}$ listed in Table 3 are the widths at half-maximum of curves 1, 2, and 3. These widths characterize the slopes of the energy resolution curves. The ratios of these widths to the values of the field parameter of the first lens corresponding

to the maximum value of the energy resolution characterize the effect of variations of the field parameters of the lenses k_1 and k_2 on the energy resolution. It can be seen from curves 1, 2, and 3 and the data of Table 2 that for variations of the field parameters close to the values $k_{1\,max}^{(1)}$, $k_{1\,max}^{(2)}$, and $k_{1\,max}^{(3)}$, the transition into the region of higher energy resolutions depends on the value of k_1/k_2. The same variations of the field parameters of the lenses give a very much larger reduction in the value of the energy resolution for large values of the ratio of the field parameters.

Table 3 lists the values of the field parameters of the first lens of the doublet $k_{1\,max}^{(1)}$, $k_{1\,max}^{(2)}$, $k_{1\,max}^{(3)}$, and $\Delta k_1^{(1)}$, $\Delta k_1^{(2)}$, $\Delta k_1^{(3)}$, obtained from curves 1, 2, and 3 of Figs. 3b and 4b and similar curves for C = 200, 314, 506, and 700 cm, and case d curves for the same values of the ratio of the field parameters. In this case F diminishes for variations of the parameters k_1 and k_2 about the values $k_{1\,max}$ and $k_{2\,max}$. This decrease is even greater for $k_1/k_2 = 0.51$. The energy resolution F depends on the field parameter k_2 of the exit lens of the doublet in the same way as it does on k_1. The only difference is in the scale of the abscissa axis. The values of F corresponding to given values of k_2 can be obtained from curves 1, 2, 3 of the same figures.

The values of the parameters $k_{1\,max}^{(1)}$, $k_{2\,max}^{(2)}$, and $k_{max}^{(3)}$, corresponding to the maximum value of the energy resolution, the widths of the energy resolution curves $\Delta k_2^{(1)}$, $\Delta k_2^{(2)}$, and $\Delta k_2^{(3)}$, and the ratios $\Delta k_2^{(1)}/k_{2\,max}^{(1)}$, $\Delta k_2^{(2)}/k_{2\,max}^{(2)}$, and $\Delta k_2^{(3)}/k_{2\,max}^{(3)}$ can also be found from curves 1, 2, and 3. These curves and Tables 2 and 3 show that a change in the distance C from the exit lens of the doublet to the place where the energy resolution is determined changes the values of $k_{1\,max}^{(1)}$, $k_{1\,max}^{(2)}$, and $k_{1\,max}^{(3)}$. As C is increased $k_{1\,max}$ and $k_{2\,max}$ are decreased, and the maxima of the energy resolution curves are shifted into the region of lower values of the field parameters. This shift is very much larger in case c. The widths of the energy resolution curves $\Delta k_1^{(1)}$, $\Delta k_1^{(2)}$, $\Delta k_1^{(3)}$, and $\Delta k_2^{(1)}$, $\Delta k_2^{(2)}$, $\Delta k_2^{(3)}$ decrease as the distance C is increased, and the energy resolution is diminished.

THE CHANGE IN THE ENERGY RESOLUTION OF A BEAM OF PROTONS WITH THE FIELD PARAMETERS k_1 AND k_2, THE RATIO k_1/k_2, AND THE DISTANCE C

The energy resolution of a beam of protons as a function of the field parameters of the lenses of the doublet k_1 and k_2 is given in ref. 1 for identical values of the field parameters and various distances C. Here, we consider arbitrary values of these parameters. Figures 5 and 6 show energy resolution curves calculated for the object (crossover of the proton beam) at the focus of the magnetic analyzer. The ratio of the parameters of each of these curves[15] is constant. For the curves of Figs 5 and 6 k_1/k_2 = 0.51 and 2.05 respectively. The energy resolution curves for the proton beam shown in Fig. 5 (1, 3, 5, 7, 9, and 11) correspond to case c with C = 100, 200, 314, 506, 700, and 800 cm. Curves 2, 4, 6, 8, 10, 12 (Fig. 5b) are calculated for case d and the same values of C. The curves shown in Fig. 6 are calculated for cases c and d and the same distances C.

These energy resolution curves are clearly symmetric, and exhibit maxima. The energy resolution at the maximum is the same for all distances C and is equal to the energy resolution of the beam due to the dispersion of the magnet alone. The values of the field parameters $k_{1\,max}$ and $k_{2\,max}$ corresponding to the largest value of the energy resolution depend strongly on whether the last lens of the doublet is converging or diverging in the plane of dispersion of the magnet.

The values of the parameters $k_{1\,max}$ and $k_{2\,max}$ also depend on the ratio k_1/k_2. The energy resolution curves are nonuniformly shifted into the region of smaller values of k_1 and k_2 when the target is moved away from the lens doublet, i.e., when the distance C is increased. The energy resolution of a beam of charged particles improves as the distance C is increased. Figure 5 shows that for

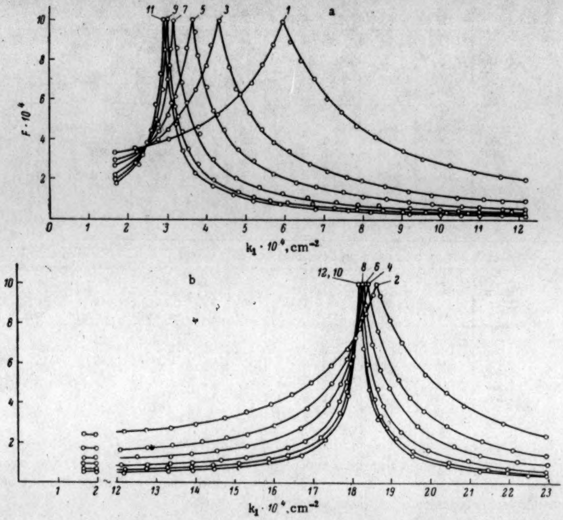

Fig. 5. Comparison of energy resolution for a beam of protons: a) in case c; b) in case d for distances C equal to 100, 200, 314, 506, 700, and 800 cm, and $k_1/k_2 = 0.51$.

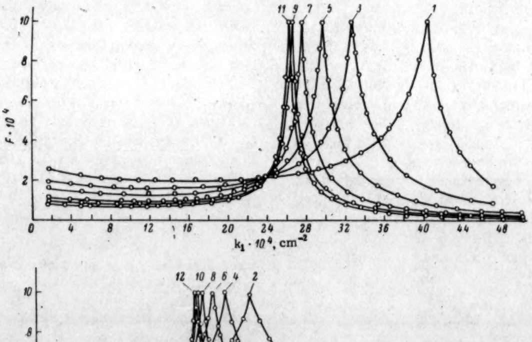

Fig. 6. Comparison of energy resolution curves for a beam of protons: a) in case c; b) in case d for distances C equal to 100, 200, 314, 506, 700, and 800 cm, and $k_1/k_2 = 2.05$.

$k_1 = 2.46 \cdot 10^{-4}$ cm^{-2} (case c) and $k_1 = 1.81 \cdot 10^{-3}$ cm^{-2} (case d) the energy resolution curves intersect at points corresponding to the regions of transition from a virtual to a real image of the object, the crossover of the beam. The values of the energy resolutions of the beam for these values of the field parameters are $3.63 \cdot 10^{-4}$ and $7.44 \cdot 10^{-4}$ respectively and remain unchanged for various values of C in the 100-800 cm range.

The energy resolution curves shown in Fig. 6 for $k_1 = 2.39 \cdot 10^{-4}$ cm^{-2} (case d) also intersect at points corresponding to regions of transition from a virtual to a real image of the object (the beam crossover) and the values of the energy resolution are $2.12 \cdot 10^{-4}$ and $5.06 \cdot 10^{-4}$ respectively and do not depend on the distance C.

RESULTS AND DISCUSSION

1. The general principles derived analytically[1] for the energy resolution of a beam of charged particles by a system consisting of a 90° deflecting magnet and a doublet of quadrupole lenses have been illustrated for arbitrary values of the field parameters of the doublet lenses.

2. For arbitrary values of the field parameters of the individual lenses of the doublet k_1 and k_2 the energy resolution function $F(k_1, k_2)$ is represented by a surface in three-dimensional F, k_1, k_2 space. Cross sections of this energy resolution surface made by planes perpendicular to the plane of its base (k_1, k_2) and passing through the origin form a family of characteristic curves with maxima. The values of the energy resolutions at all these maxima are the same and equal to the value of the energy resolution of the beam produced by the deflecting magnet alone.

3. The necessary and sufficient condition for the preservation and reproduction of a chosen energy resolution curve for the beam and, thus, the preservation and reproduction of the value of the energy resolution for a change of the field parameters k_1 and k_2 of the individual lenses of the doublet is the preservation of a constant value of k_1/k_2.

4. The differences in the energy resolutions of the beam for $k_1/k_2 = 1.02$, 2.05, and 0.51 and cases c and d have been determined.

5. The value of the energy resolution of a beam of protons in the transition regions from a virtual to a real image of the object (the beam crossover) for various values of k_1/k_2 does not depend on the value of C, the distance from the exit lens of the doublet to the beam crossover plane, where the energy resolution is determined.

6. For $k_1/k_2 = 1.02$, 2.05, and 0.51, various distances C, and cases c and d differences were found in the effect of variations of k_1 and k_2 on the energy resolution of the beam. The energy resolution curves have been compared in these cases. The values of $k_{1\,\max}$ and $k_{2\,\max}$ corresponding to the largest value of the energy resolution were determined. The widths of the curves have been found.

(Submitted June 22, 1973
Zh. Tekh. Fiz., 44, 491-501 (March 1974)

The possibility of deriving a systematic magnetohydrodynamic theory for pulsed xenon tubes is analyzed. At temperatures high enough so that the emission of the discharge approaches that of an absolute blackbody and the energy loss at the walls is negligible it is possible to find an exact solution for the problem of the equilibrium and stability of radiating discharges confined by walls on the basis of the radiative magnetohydrodynamic model. The results agree with experimental data and available numerical calculations.

1. INTRODUCTION

The equilibrium and stability of high-current discharges in a dense plasma under conditions of intense radiative heat transfer have been studied theoretically and experimentally[1-6] in connection with the design of high-intensity pulsed light sources. The emitter must have properties corresponding to a brightness temperature of 3-5 eV in order to provide a maximum radiation in the spectral range near 2000 Å. At these high temperatures it is extremely undesirable to allow contact between the discharge channel and the walls of the vessel. Therefore, the discharge current in such sources must be high enough to provide magnetic confinement of the plasma in a limited volume by means of the self current (the pinch effect). However, such a discharge confined at equilibrium by the magnetic field of a current turns out to be unstable with respect to the development of strong instabilities. The conversion coefficient for the radiation, i.e., the ratio of the radiated energy to that stored in the system, is approximately the same as in ordinary pulsed gas-discharge tubes.[7,8] Accordingly, in those cases in which the spectral range of interest lies in the visible region, the most efficient sources would apparently be relatively low-current discharges in a dense plasma having a brightness temperature of 1-2 eV. Examples of such sources are ordinary pulsed xenon tubes. Here the term "low-current discharge" means that the discharge current is not high enough to lead to the pinch effect; under these conditions the plasma is confined in equilibrium by the walls of the discharge tube. Under these conditions strong instabilities cannot be tolerated, so in this sense we can speak of a discharge stabilized by the walls of the discharge chamber (stabilization of this type is clearly displayed in the xenon pumping tubes mentioned above).

Much effort has been devoted to theoretical calculations of the physical properties of such wall-confined discharges.[8-12] In most of this work,[8-11] however, either the plasma is assumed to be completely optically transparent or empirical corrections are introduced for the optical grayness of the discharge.[8,10] Clearly, this model of the discharge is valid only at low current densities, low temperatures, and low plasma densities; furthermore, it cannot yield the spectral distribution of the radiation. Accordingly, an approximate numerical calculation has been carried out[12] for the properties of the gas-discharge plasma in pulsed radiation sources. The results of this calculation agree with experimental results,[13,14] even though the temperature is actually assumed to be radially homogeneous in ref. 12. This homogeneity seems unlikely in the transparency region of the plasma; it requires a special study.

Analysis shows, however, that at high temperatures, $T \geqslant 1.5$ eV, there are broad ranges of the external discharge properties (the specific power supplied to the discharge, W; the discharge current density j_0; and the initial pressure in the tube, p_0) for which the discharge radiates like an absolute blackbody and over which a rigorous analytic calculation is possible.

In the present work we report the results of such a calculation, analyze the range of applicability of the derived equations, and compare the results with the results of ref. 12 and with experiment.

2. INITIAL ASSUMPTIONS AND BASIC EQUATIONS

We consider a discharge confined by walls in which the temperature is 1.5-2.0 eV and in which the initial pressure ranges from some tenths of an atmosphere to several atmospheres (typical conditions in pulsed xenon tubes). Under these conditions, as follows from data reported elsewhere,[8,10,12] the gas in the discharge channel can be assumed to be completely ionized. Furthermore, for a typical discharge-tube diameter of the order of 1 cm, the radiation of the discharge at such high temperatures and plasma densities differs only slightly from that of an absolute blackbody, as has been shown by calculations[12] and experiments.[9,14] Under these conditions we can use the approximation of radiative heat transfer, i.e., neglect electronic heat transfer in comparison with radiative transfer.

In accordance with the definition in the introduction we require two conditions: First, we require that the magnetic pressure of the discharge current be small in comparison with the kinetic pressure of the plasma,

$$\frac{B^2}{8\pi} \ll p; \tag{2.1}$$

Second, we require that the pressure in the discharge be constant,

$$p = (1+z)n\varkappa T = p_w = \text{const}, \tag{2.2}$$

where p_w is the pressure at the wall of the discharge tube, z is the average ion charge, $\varkappa$ is the Boltzmann constant, and n is the charged-particle density in the plasma.

Under these assumptions it is a straightforward matter to write the complete system of equations used to study any transient phenomena in this discharge. This system of equations is similar to the usual system of MHD equations with radiative heat transfer. They follow from the system of equations introduced in ref. 2, in which we incorporate conditions (2.1) and (2.2) (we will not write these equations out explicitly here).

We restrict the analysis to the case of an equilibrium, steady-state [d/(dt) = 0, v = 0] discharge, for which we can write this system of equations as

$$\left.\begin{aligned} &\operatorname{curl}\mathbf{B}=\frac{4\pi}{c}\sigma\mathbf{E};\\ &\operatorname{div}\left\{\frac{c^2}{16\pi^2}\frac{1}{\sigma}[\operatorname{curl}\mathbf{B}\times\mathbf{B}]-\chi\operatorname{grad}T\right\}=0,\\ &p=(1+z)n\varkappa T=p_w=\text{const},\end{aligned}\right\}\qquad(2.3)$$

where

$$\sigma=\alpha T^n,\quad \chi=\beta\frac{T^m}{p^k}\qquad(2.4)$$

are the conductivity and radiation thermal diffusivity of the plasma. The values of m and k, which govern the functional dependence of the radiation diffusivity on the temperature and pressure, are themselves governed by the mechanism by which light is absorbed in the plasma (below we refine these values for specific cases). Under conditions of complete ionization, the value of n is a weak function of the nature of the material This functional dependence varies strongly as a function of the degree of ionization of the plasma.

Finally, to close the problem, we require a symmetric temperature profile over the cross section of the discharge, and we specify the energy balance in the discharge under the assumption that the energy which appears as Joule heat is partially carried away from the plasma surface as blackbody radiation and partially expended in heating and evaporating the surfaces confining the discharge:

$$-\int_V\sigma E^2d\mathbf{r}+S\delta T^4(a)+SQ_w=0.\qquad(2.5)$$

Here V and S are the volume and surface area of the plasma, T(*a*) is the temperature at the boundary of this volume, and Q_W is the specific rate at which heat is evolved at the tube walls, a function of the actual wall temperature T_W. It is shown elsewhere[12] that at temperatures of 1-2 eV we can write

$$\left.\begin{aligned} &T_w\approx 0.8T(a),\\ &Q_w(T_w)\simeq 0.125Q_w(T(a))\\ &=\frac{0.125n}{\sqrt{2\pi M_i}}(\varkappa T(a))^{3/2}\left\{\frac{1}{2}\ln\frac{M_i}{m}+4+\frac{E_i}{\varkappa T(a)}\right\},\end{aligned}\right\}\qquad(2.6)$$

where M_i is the ion mass and E_i is the ionization energy of an atom in the plasma. Comparison of the loss due to radiation and the loss at the walls shows that it is important to take Q_W into account over broad ranges of plasma pressures and temperatures. However, at initial tube pressures which are not too high and at high temperatures T(*a*), we can neglect Q_W. For example, with p_0 = 300 torr, a typical initial pressure in a xenon discharge, and with T = 2 eV, the loss at the walls is about 20% of the radiation loss.[15]

3. EQUILIBRIUM OF A PLANE DISCHARGE

We consider a plane plasma layer which is inhomogeneous (bounded) along the x axis and to which is applied a homogeneous, fixed electric field $\mathbf{E}_0$ = const along the z axis (there is no skinning of the field in the plasma because of its low conductivity). This case corresponds to some extent to pulsed tubes with a rectangular cross section[16] and, partially, to "hollow" pulsed tubes with a thin plasma layer between external and internal cylindrical shells.[17] Here the magnetic field obviously lies along the y axis and vanishes at the axis.

System (2.3) can be solved exactly if χ(T) and σ(T) are functions of the plasma temperature alone. This condition is in fact satisfied for this discharge, because of the condition p = const. Accordingly, in the most general case, we set

$$\chi=\beta_0T^m,\quad \sigma=\alpha T^n.\qquad(3.1)$$

Then, we find an equation for T from Eqs. (2.3):

$$\frac{d}{dx}T^m\frac{dT}{dx}+T^n\delta=0,\quad \delta=\frac{\alpha}{\beta}E_0^2=\text{const},\qquad(3.2)$$

which is to be solved with the boundary conditions

$$T|_{x=0}=T(0)\quad \left.\frac{dT}{dx}\right|_{x=0}=0.\qquad(3.3)$$

This equation can be easily integrated by means of the variable substitution u = (1/2)[dT/(dx)]²; when the odd parity of the derivative dT/dx is taken into account, this equation yields the temperature distribution in quadratures:

$$\int_T^{T(0)}\frac{dT}{F[T,T(0)]}=|x|,\qquad(3.4)$$

where

$$F[T,T(0)]=T(0)^{-m}\left\{\frac{2\delta T(0)^{n+m+1}}{n+m+1}\left[1-\left(\frac{T}{T(0)}\right)^{m+n+1}\right]\right\}^{1/2}.\qquad(3.5)$$

Knowing T(x), we can easily find the density distribution ρ(x) and the magnetic field distribution B(x) from Eqs. (2.3). In particular, we find

$$\rho(x)=\frac{np_w}{(1+z)\varkappa T(x)}.\qquad(3.6)$$

Equations (3.5) and (3.6) determine the equilibrium of the discharge at a given temperature at the discharge axis, T(0), determined from the energy balance. From (2.5) we then find

$$-2\int_0^a\sigma E^2dx+2\delta T^4(0)=0,\qquad(3.7)$$

where $2a$ is the thickness of the discharge. We have neglected processes involving energy absorption by the walls of the discharge tube in this equation, in correspondence with the estimates above, and also in view of the known[8,16-20] high-energy efficiency of pulsed xenon tubes as radiation sources (the efficiency reaches 60-85% over the spectral range 1800-450 nm, in terms of the electrical energy dissipated in the tubes).

From (3.7) and

$$\int_{T(a)}^{T(0)} \frac{dT}{F[T,\ T(0)]} = a \qquad (3.8)$$

we determine T(0) and T(a), thereby completely solving the problem for the equilibrium of a wall-confined discharge in a dense, optically opaque plasma.

The general equations derived here, which govern the equilibrium characteristics of the discharge, can be simplified in two limiting cases: a) when the thickness a is so small that the temperature is nearly homogeneous over the plasma cross section, i.e., in the case T(0) ≃ T(a); b) when a is large and T(0) ≫ T(a). Let us consider these limiting cases in more detail.

Case a. When the discharge thickness a is so small that T(0) ≃ T(a), we can use (3.4) and expand in terms of the small deviation from the maximum temperature, finding

$$\left.\begin{aligned} T(x) &= T(0)\left[1 - \frac{x^2}{x_T^2}\right], \\ x_T^2 &= \frac{2}{\delta}\, T(0)^{m-n+1} = \frac{2\beta_0}{\alpha E_0^2}\, T(0)^{m-n+1}. \end{aligned}\right\} \qquad (3.9)$$

On the other hand, from the thermal-balance equation, (3.7), we find

$$a = \frac{\delta T(0)^{n-4}}{\alpha E^2}\left[1 - \frac{(4-n)\,a^2}{x_T^2}\right]. \qquad (3.10)$$

It is easy to see that Eqs. (3.9) and (3.10) hold only if $a^2 \ll x_T^2$ or, equivalently,

$$E > \frac{\delta T(0)^{\frac{7-n-m}{2}}}{\sqrt{2a\beta}}. \qquad (3.11)$$

We now incorporate the relation $\chi = (16/3)\hat{\sigma} l_p T(0)^3 = \beta_0 T(0)^m$ and require satisfaction of the obvious condition for the applicability of the approximation of radiative heat transfer: $2a > l_p$. Then we find

$$E > \frac{4\sqrt{2}}{\sqrt{3}}\, \frac{\delta T(0)^{\frac{7-n-m}{2}}}{\sqrt{a\beta}}. \qquad (3.12)$$

If condition (3.11) is not satisfied, the plasma temperature in the discharge cannot be assumed to be only slightly inhomogeneous, and we instead have case b. If inequality (3.12) is not satisfied, we have a situation corresponding to the conversion of the discharge from opaque to transparent. Accordingly, case a holds in an optically dense plasma over a quite narrow range of plasma properties, given by the inequalities

$$\frac{8}{\sqrt{3}} > \frac{E\sqrt{2a\beta}}{\delta T(0)^{\frac{7-n-m}{2}}} > 1. \qquad (3.13)$$

Case b. We now consider the opposite case, in which T(0) > T(a) and in which the plasma temperature varies significantly over the discharge thickness. In this case, working from Eq. (3.4) and introducing $t = [T/T(0)]^{(m-n+1)/2}$, we find

$$T(0)^{\frac{m-n+1}{2}} = \frac{a\sqrt{2\delta(m+n+1)}}{B\left(1 - \frac{n}{m+n+1},\ \frac{1}{2}\right)}, \qquad (3.14)$$

where

$$B(p,\ q) = \int_0^1 t^{p-1}(1-t)^{q-1}\,dt = \frac{\Gamma(p)\,\Gamma(q)}{\Gamma(p+q)}. \qquad (3.15)$$

On the other hand, from energy-balance equation (3.7) we find

$$\hat{\sigma} T^4(0) = \alpha E^2 \int_{T(a)}^{T(0)} \frac{T^n(x)\,dT}{F[T,\ T(0)]} \simeq \alpha E^2 \int_0^{T(0)} \frac{T^n dT}{F[T,\ T(0)]}. \qquad (3.16)$$

Now carrying out the integration by the method described above, and using (3.14), we finally find the desired quantity T(0), which is a characteristic of the radiation of the discharge:

$$\hat{\sigma} T(a)^4 = E_0 \sqrt{\frac{2\alpha\beta T(0)^{n+m+1}}{n+m+1}}. \qquad (3.17)$$

Here T(0) is given by (3.14).

Finally, we write the voltage–current characteristic of the discharge. It is easy to see that the total current per unit width of the discharge is

$$I_0 = 2\int_0^a j_0\,dx = 2\int_0^a \sigma E_0\,dx = 2\alpha E_0 \int_{T(a)}^{T(0)} \frac{T^n dT}{F[T,\ T(0)]} \qquad (3.18)$$

Now, using (3.4) and (3.7) we find

$$I_0 = \frac{2\hat{\sigma} T^4(a)}{E_0}, \quad \int_{T(a)}^{T(0)} \frac{dT}{F[T,\ T(0)]} = a. \qquad (3.19)$$

Equations (3.18) and (3.19) completely determine the voltage–current characteristic of the discharge, $I_0(E)$. (This characteristic can be written out explicitly for limiting cases a and b considered above.)

In case a, using Eq. (3.10) we find

$$I_0 = 2aE_0T^n(0) = 2aE_0\left(\frac{\alpha a E_0^2}{\delta}\right)^{\frac{n}{4-n}} \sim E^{\frac{4+n}{4-n}}. \tag{3.20}$$

In case b, we find from Eqs. (3.14) and (3.17)

$$I_0 = 2\sqrt{\frac{2\alpha\beta T(0)^{n+m+1}}{n+m+1}} = \sqrt{\frac{8\alpha\beta}{n+m+1}} \times \left\{\frac{a\sqrt{2\frac{\alpha}{\beta}E_0^2(n+m+1)}}{B\left(\frac{m+1}{n+m+1}, \frac{1}{2}\right)}\right\}^{\frac{m+n+1}{m-n+1}} \sim E^{\frac{m+n+1}{m-n+1}}. \tag{3.21}$$

Finally, it should be kept in mind that the total discharge current is bounded from above by inequality (2.1), which leads to the condition

$$I_0 < c\sqrt{\frac{2p_w}{\pi}}. \tag{3.22}$$

Only if this condition is satisfied are all the equations derived above valid. It is easy to see that (3.22) gives an upper limit on the discharge field E for a given discharge width. This limitation must be taken into account along with (3.13).

4. EQUILIBRIUM OF A CYLINDRICAL DISCHARGE

Let us consider the case in which the plasma is cylindrical, an assumption corresponding to the situation in an ordinary tubular pulsed xenon tube – a common situation in practice. As in the case of a plane discharge, we can reduce system (2.3) to an equation for T:

$$\frac{1}{r}\frac{d}{dr}rT^m\frac{dT}{dr} + T^n\delta = 0, \tag{4.1}$$

where δ is given by Eq. (3.2). The boundary conditions are analogous to (3.3). We restrict the analysis to the case in which the temperature varies only slightly over the discharge – the case of most practical interest. Then we easily find

$$T(r) = T(0)\left[1 - \frac{r^2}{r_T^2}\right], \quad r_T = \frac{4}{\delta}T(0)^{m-n+1} = \frac{4\beta}{\alpha E^2}T(0)^{m-n+1}. \tag{4.2}$$

The temperature at the discharge axis, T(0), is calculated from the energy-balance equation in the discharge. Assuming as before that the discharge radiates as an absolute blackbody, we can write this equation as

$$\delta T^4(0)\left[1 - \frac{4a^2}{r_T^2}\right] = \frac{\alpha E^2 a}{2}T^n(0)\left[1 - \frac{na^2}{2r_T^2}\right], \tag{4.3}$$

where *a* is the radius of the discharge tube. Hence we can write, approximately,

$$T(0) = \left(\frac{\alpha E^2 a}{2\delta}\right)^{1/(4-n)}. \tag{4.4}$$

From the condition for the homogeneity of the temperature ($a \ll r_T^2$) and the condition for the applicability of the approximation of radiative heat transfer ($a > l_p$), we find restrictions on the electric field in the discharge [cf. (3.13)]:

$$\sqrt{\frac{32}{3}} > \frac{E\sqrt{\alpha\beta}}{\delta T(0)^{(7-m-n)/2}} = \xi(E, T(0)) > 1. \tag{4.5}$$

From the condition under which we can neglect the magnetic pressure we find a restriction on the total discharge current:

$$I < ca\sqrt{2\pi p_w}. \tag{4.6}$$

Finally, the voltage–current characteristic of the discharge is

$$I = 2\pi\int_0^a jr\,dr = \pi a^2\alpha\left(\frac{\alpha a}{2\delta}\right)^{n/(4-n)}E^{(4+n)/(4-n)}. \tag{4.7}$$

We note that here the current is of the ordinary dimensionality, in contrast with the currents in (3.20) and (3.22).

5. STABILITY OF A WALL-CONFINED DISCHARGE

In these discharges the magnetic field of the current is negligibly weak, so there are no strong instabilities such as constrictions and kinks, which are typical of high-current self-constricted discharges and are consequences of the inequality of the magnetic and MHD pressures.[1,2] The only dangerous instability could be the superheating instability,[3] because in a completely ionized plasma there can be no current-contraction mechanisms (there can be no shunting of the glow discharge, accompanied by an abrupt current increase), which are characteristic of a weakly ionized plasma in which the gas temperature is significantly inhomogeneous over the cross section of the discharge tube.[21] To analyze the possible growth of this instability we start from the equation

$$\rho T\left[\frac{\partial s}{\partial t} + (\mathbf{v}\nabla)s\right] = \sigma E^2 - \operatorname{div}\chi\nabla T, \tag{5.1}$$

where s is the entropy per unit mass of the plasma. In the case of an ideal, completely ionized plasma we have

$$s = \frac{(1+z)\varkappa}{M_i}\ln\frac{T^{3/2}}{\rho}. \tag{5.2}$$

If

$$\frac{c^2}{4\pi\sigma a^2} \gg \omega \sim \frac{j^2}{\sigma p_w}, \tag{5.3}$$

and there is no skinning of the field in the plasma, whether the superheating instability occurs depends on the slope of the function

$$\varphi(T) = \frac{T\chi(T)}{\sigma(T)}. \tag{5.4}$$

As shown previously,[22] the discharge displays the superheating instability if $\varphi'(T) < 0$, but this instability cannot develop if $\varphi'(T) > 0$. If

$$\omega \sim \frac{j^2}{\sigma p_w} \gg \frac{v_s}{a}, \tag{5.5}$$

the plasma density does not manage to change during the growth of the instability; we can write [cf. (2.4)] $\sigma \sim T^n$ and $\chi \sim T^{m-k}$ for the conductivity and the radiation thermal diffusivity in this case. As a result we find

$$\varphi(T) \sim T^{m-k-n+1}. \tag{5.6}$$

The condition for the onset of the instability is

$$m-k-n+1<0. \tag{5.7}$$

If the inequality opposite to (5.5) holds, we have $\sigma \sim T^n$ and $\chi \sim T^m$, and the necessary condition for the onset of the superheating instability is

$$m-n+1<0. \tag{5.8}$$

Finally, according to (5.1), the growth rate for the superheating instability, under conditions such that this instability can occur, is determined by the characteristic time for Joule heating (or supercooling) of the plasma and is given in order of magnitude by

$$\operatorname{Im}\omega \simeq \frac{j^2}{\sigma p_w}. \tag{5.9}$$

It is important to note that conditions (5.7) and (5.8) are necessary but not sufficient conditions. For the development of the superheating instability, another necessary condition is

$$\sigma E^2 \geqslant \frac{\varkappa T}{r_T^2}, \tag{5.10}$$

where r_T is the scale of the inhomogeneity of the plasma temperature in the equilibrium (or quasiequilibrium) state of the discharge.

6. DISCUSSION OF RESULTS

These results are of a completely general nature and hold for discharges in arbitrary optically opaque media. Let us apply them to the case of a discharge in xenon at initial pressure of $p_0 \lessapprox 1$ atm and at $T \simeq 1.5$-2 eV. At these pressures and temperatures we have $z = 1$, and the conductivity and thermal diffusivity of the xenon are described by

$$\sigma = aT^{3/2}, \quad n = \frac{3}{2}, \quad a = 4\cdot 10^7,$$
$$\chi = \beta_0 T^{13/2}, \quad m = \frac{13}{2}, \quad \beta_0 = \frac{2.5\cdot 10^{-8}}{p_w^2}, \quad k = 2. \tag{6.1}$$

Here we have used the ordinary expression for the conductivity of a completely ionized plasma for σ, while for the radiation thermal diffusivity we have used the expression given by the Kramers-Unsöld approximation for photoionization absorption by xenon atoms.[23]

We first note that $m-n+1 = 6 > 0$ and $m-n-k+1 = 4 > 0$. Accordingly, a discharge in xenon under conditions such that the xenon is optically opaque is stable with respect to perturbations of the superheating type.

The Rosseland mean free path for light in xenon under these conditions is

$$l_p = \beta_1 T^{7/2}, \quad \beta_1 = \frac{3}{16}\frac{\beta}{\delta}. \tag{6.2}$$

At $p_0 \simeq 0.5$ atm $\simeq 0.5\cdot 10^5$ dyn/cm² and with $T \simeq 10^4$ °K we find $l_p \simeq 0.5$ cm, $\sigma_0 \simeq 4\cdot 10^{13}$ sec⁻¹, and $\chi \simeq 1.6\cdot 10^7$ erg/(cm · g · cm) [sic].

According to (4.5), with $T(0) \simeq 10^4$ °K a discharge in xenon will be nearly homogeneous with respect to the temperature if the field E_0 lies in the range

$$250\,\text{V/cm} \simeq 0.8\ \text{cgs esu} > E_0 > 0.25\ \text{cgs esu} \simeq 70\ \text{V/cm}. \tag{6.3}$$

In strong fields, the condition for optical opacity of the plasma is not satisfied, while in weak fields the condition for homogeneity of the temperature is not satisfied. We assume $E \simeq 100$ V/cm $\simeq 1/3$ cgs esu; then from (3.14) we find the discharge width to be

$$2a = 0.3\ \text{cm}. \tag{6.4}$$

The radiation of the plasma under these conditions is similar to that of a blackbody at $T_0 = 1$ eV, and the voltage–current characteristic, according to (4.7), is

$$j_0 = 1.1\cdot 10^{14} E_0^{11/4}. \tag{6.5}$$

For a comparison of this theoretical characteristic with experimental data it is convenient to rewrite the characteristic as

$$\sigma = 0.39 j^{7/11}. \tag{6.6}$$

For pulsed krypton and xenon tubes having inside diameters from 0.2 to 1.4 cm, a cold gas pressure of ~0.15 atm, and electric fields from 15 to 150 V/cm, it has been found experimentally[8] that σ can be described satisfactorily as a function of j by

$$\sigma = 4.66 j^{1/2}, \tag{6.7}$$

which also turns out to be approximately valid for a much broader range of electric fields (up to 6000 V/cm) and for much broader ranges of the other parameters.

In ref. 24 for xenon tubes of approximately the same diameters, at cold pressures of 0.25-1 atm and at current densities of 0.4-10 kA/cm^2, it is found that σ is described accurately as a function of j by the empirical equation

$$\sigma = 0.885 j^{1/2}. \tag{6.8}$$

The following empirical equation is found in ref. 25 for xenon tubes with inside diameters from 0.5 to 1.8 mm, at a cold pressure of about 0.5 atm:

$$\sigma = A j^{1/2}. \tag{6.9}$$

Here A increases from 0.2 to 0.56 with increasing diameter and increasing rise time of the current.

Finally, a study[26] of xenon tubes with inside diameters of 0.7 and 1.6 cm and cold pressures of 0.5-0.8 atm at current densities of 0.3-3 kA/cm^2 reveals that empirical equation (6.8) is satisfied extremely well; for a cold pressure of 0.15 atm, an analogous equation is found, in which the coefficient of $j^{1/2}$ is about 1.15. Some increase in σ with decreasing pressure has been observed in several cases (see, e.g., ref. 8), and we can assume that the increase in A noted in ref. 25 with increasing diameter and increasing current rise time is a consequence of the escape of some of the gas from the working part of the tube into the cold regions near the electrodes and to a corresponding reduction of the gas density between the electrodes (the volumes near the electrodes are minimized in ref. 26, and no functional dependence of σ on the diameter is detected).

Functional dependence (6.8) is also verified in ref. 27 over broader ranges of the parameters. The differences among empirical relations (6.7)-(6.9) are seen from Fig. 1 to be slight, possibly within the corresponding experimental errors, for the current-density range studied in detail. Theoretical curve 4 in this figure, plotted from (6.6), lies quite close to all the experimental curves, implying a satisfactory agreement between theory and experiment in terms of the voltage−current characteristic.

Returning to Eq. (6.5), we find, with E = 1/3 cgs esu, we have $j_0 \simeq 3300$ A/cm^2, a result which is consistent with inequality (4.8).

At fields weaker than the lower limit in (6.3), the plasma temperature becomes very inhomogeneous in the discharge, and the efficiency of the source must fall off appreciably, again in agreement with experiment.[8] For example, with E = 30 V/cm, we find (p_0 = 1 atm) $T(0) \simeq 1$ eV from (3.14) and $T(a)$ = 6400°K from (3.17). Figure 2 shows the temperature in the discharge as a function of the current density, calculated theoretically from Eq. (4.4); also shown here is the result of a numerical calculation[12] and experimental results.[28-30] We see that there is a satisfactory agreement at high current densities, $j_0 \gg 5$ kA/cm^2. Under these conditions the discharge parameters are such that all the simplifications used in this paper are valid. At lower current densities the discrepancy between the theoretical and experimental results increases; nevertheless, our simple analytic relations still yield correct estimates of the basic discharge parameters.

Nonlinear statistical theory of a condensate of plasmons.
II. Stochastic heating of plasma ions by large-scale Langmuir turbulence

F. Kh. Khakimov
V. I. Lenin Tadzhik State University, Dushanbe

(Submitted May 14, 1973; resubmitted September 7, 1973)
Zh. Tekh. Fiz., 44, 502-507 (March 1974)

The heating of ions due to low-frequency waves generated by a Langmuir turbulence is evaluated. The calculations are carried out under the assumption that the ion motion is one-dimensional (the ions are "magnetized").

INTRODUCTION

Low-frequency waves are known to be excited in a plasma with plasma turbulence;[1,2] when these waves interact with the plasma particles, the latter are heated. Khakimov and Tsytovich[3] analyzed the stochastic heating of electrons due to low-frequency waves generated by plasma turbulence. These authors found the spectra of a strong turbulence of low-frequency pulsations excited by plasma turbulence. In the present paper we analyze the stochastic heating of ions under the same conditions. As in ref. 3, we assume the ion motion to be one-dimensional; we assume a strong magnetic field ($\omega_{Hi} \gg \omega_{pi}$), but consider the case $v_{li} < \omega/k < v_{Te}$ and $v_{li} < v_{Ti}$, since $\omega < kv_{Ti} < k_1 v_{Ti}$, i.e., $k < k_1$, where k_1 is the wave number of the plasma waves.

The results show that the ion heating rate differs by a factor v_{Ti}/v_{Te} from the electron heating rate.

1. LINEAR THEORY OF THE MODULATION INSTABILITY

A nonlinear theory for the absorption of plasma waves is derived in ref. 3; in particular, an analysis is made of the profound change in the electromagnetic properties of a plasma at low frequencies under the influence of high-frequency turbulence. Our purpose here is to find the analytic form of the low-frequency dielectric constant of the plasma, which is a linear function of the spectral energy of the turbulence, W_{k_1,ω_1}:

$$W = \int W_{k_1,\omega_1} dk_1 d\omega_1. \tag{1}$$

Here, W is the total energy of the condensate.

To find the form of the dielectric constant we use the equation $\operatorname{div} E = 4\pi e n$ and the quasilinear equation for the distribution function, which takes account of the effect of high-frequency waves:

$$-i(\omega - kv) f^{R(1)i}_{k,\omega} = -\frac{e}{m_i} E^R_{k,\omega} \frac{\partial \Phi^i}{\partial v} + \frac{\partial}{\partial v} D_1 \frac{\partial \Phi^i}{\partial v}. \tag{2}$$

Here Φ^i is the ion distribution function for the basic turbulent state,

$$D_1 = i(\omega - kv) n^{(1)}_k \left(\frac{e}{m_i}\right)^2 \frac{\omega^2_{pi}}{n_0} \int \frac{I_{k_1,\omega_1} dk_1 d\omega_1}{\bar{\varepsilon}(k - k_1,\ \omega - \omega_1)\, \omega_1 (\omega_1 - \omega)^3} \tag{3}$$

is the diffusion coefficient, and I_{k_1,ω_1} is the correlation function for the high-frequency fluctuations.

In our case, $kv_{li} < \omega < kv_{Ti}$, for one-dimensional plasma turbulence

$$\omega_{k_1} = \omega_{pe} + \frac{3}{2} \frac{k_1 v^2_{Te}}{\omega_{pe}}$$

we have

$$\varepsilon^i(k,\ \omega) = 1 + \frac{\dfrac{\omega^2_{pi}}{k^2 v^2_{Ti}}}{1 + \dfrac{n_0}{v^2_{Ti}} d_1}, \tag{4}$$

where

$$d_1 = \left(\frac{e}{m_i}\right)^2 \frac{\omega^2_{pi}}{n_0} \int \frac{I_{k_1,\omega_1} dk_1 d\omega_1}{\bar{\varepsilon}(k - k_1,\ \omega - \omega_1)\, \omega_1 (\omega_1 - \omega)^3}. \tag{5}$$

For $kv_{li} < \omega < kv_{Te}$ we have $d_1 \approx 3k^2 v^2_{Te} W / 4n_0^2 m_e \omega^2$; then

$$\varepsilon^e(k,\ \omega) = 1 + \frac{\dfrac{\omega^2_{pe}}{k^2 v^2_{Te}}}{1 + \dfrac{3W}{4n_0 T_e} \dfrac{k^2 v^2_{Te}}{\omega^2}}. \tag{6}$$

Using (4) and (6) under the conditions $\varepsilon^e(k, \omega)$, $\varepsilon^i(k, \omega) \gg 1$, we find the dispersion relation

$$\omega^2 = -k^2 v^2_{\sim} \frac{1 + \left(\dfrac{m_e}{m_i}\right)^{1/2}}{1 + \dfrac{T_i}{T_e}}. \tag{7}$$

Here $v^2_{\sim} = 3W/4n_0 m_e$. When $\omega > kv_{\sim}(T_e/T_i)^{1/2}(m_e/m_i)^{1/4}$ we have

$$\omega^2 = -k^2 v^2_{\sim} \frac{T_e}{T_e + T_i}. \tag{8}$$

Equation (8) shows an aperiodic buildup of the waves:

$$\omega = \pm ikv_{\sim}\left(1 + \frac{T_i}{T_e}\right)^{-1/2}. \tag{9}$$

In the opposite limiting case $\omega < kv_{\sim}(T_e/T_i)^{1/2}[m_e \cdot (m_i)^{-1}]^{1/4}$,

$$\omega^2 = -k^2v_{\sim}^2\left(1 + \sqrt{\frac{m_e}{m_i}}\right). \tag{10}$$

2. EQUATION FOR THE AVERAGED DISTRIBUTION FUNCTION

Following the calculation procedure of ref. 3, and neglecting the smallness of the phase velocities of the low-frequency waves ($\omega/k \ll \omega_L/k_L$, where ω_L and k_L are the frequency and wave number of the plasma waves), we find an equation for Φ which takes account of the average effect of both the high-frequency and low-frequency waves:

$$\frac{\partial\Phi}{\partial t} + v\frac{\partial\Phi}{\partial z} = I_1 + I_2, \tag{11}$$

where

$$I_1 = -\frac{e}{m_i}\left\langle E^R \frac{\partial f^{R(1)}}{\partial v}\right\rangle_l = -\frac{e}{m_i}\frac{\partial}{\partial v}\int \left\langle E^R_{k',\omega'} f^{R(1)}_{k,\omega}\right\rangle_l dk\,dk'\,d\omega\,d\omega', \tag{12}$$

$$\begin{aligned} I_2 &= -\frac{e}{m_i}\left\langle E^{T(1)} \frac{\partial f^{T(1)}}{\partial v}\right\rangle_{h,l} \\ &= -\frac{e}{m_i}\frac{\partial}{\partial v}\int \left\langle E^{T(1)}_{k_1'',\omega_1''} f^{T(1)}_{k_1',\omega_1'}\right\rangle_{h,l} dk_1'\,dk_1''\,d\omega_1'\,d\omega_1'', \end{aligned} \tag{13}$$

and "h" and "l" denote averages over high and low frequencies.

The first quasilinear integral I_1 takes account of the correlation of low-frequency fluctuations, while I_2 takes account of the effect of high-frequency fields on the low-frequency fields and vice versa.

To determine I_1 we must know the exact form of distribution function $f^{R(1)}_{k,\omega}$.

However, we note that the correction to the ion distribution function due to the high-frequency fields turns out to be smaller than the electron correction, so that the ion distribution function is

$$f^{R(1)}_{k,\omega} = -i\frac{e}{m_i}\frac{E^R_{k,\omega}}{\omega - kv}\frac{\partial\Phi}{\partial v}. \tag{14}$$

Substituting this quantity into (12) we find

$$\begin{aligned} I_1 &= i\left(\frac{e}{m_i}\right)^2\frac{\partial}{\partial v}\int \frac{\left\langle E^R_{k,\omega}E^R_{k',\omega'}\right\rangle l}{\omega - kv}\frac{\partial\Phi}{\partial v}\,dk\,dk'\,d\omega\,d\omega' \\ &= 4\pi i\left(\frac{e}{m_i}\right)^2\frac{\partial}{\partial v}\int \frac{w_{k,\omega}}{\omega - kv}\frac{\partial\Phi}{\partial v}\,dk\,d\omega \\ &= \frac{4\pi^2e^2}{m_i^2}\frac{\partial}{\partial v}\int w_{k,\omega}\delta(\omega - kv)\frac{\partial\Phi}{\partial v}\,dk\,d\omega. \end{aligned} \tag{15}$$

The second quasilinear collison integral I_2 can be determined by using the expression for the linear part of $f^{T\,(1)}_{k,\omega}$ (ref. 4). Then we find

$$\begin{aligned} I_2 &= i\left(\frac{e}{m_i}\right)^2\frac{\partial}{\partial v}\int \frac{\left\langle E^{T(1)}_{k_1'',\omega_1''}E^{T(1)}_{k_1',\omega_1'}\right\rangle}{\omega_1' - k_1'v}\frac{\partial\Phi}{\partial v}\,dk_1'\,dk_1''\,d\omega_1'\,d\omega_1'' \\ &= i\left(\frac{e}{m_i}\right)^2\frac{\partial}{\partial v}\int \frac{\left|E^{T(1)}_{k_1',\omega_1'}\right|^2}{\omega_1' - k_1'v}\frac{\partial\Phi}{\partial v}\delta(k_1' + k_1'')\,\delta(\omega_1' + \omega_1'')\,dk_1'\,dk_1''\,d\omega_1'\,d\omega_1'' \\ &= i\left(\frac{e}{m_i}\right)^2\frac{\partial}{\partial v}\int \frac{\left|E^{T(1)}_{k_1',\omega_1'}\right|^2}{\omega_1' - k_1'v}\frac{\partial\Phi}{\partial v}\,dk_1'\,d\omega_1' \\ &= -\pi\left(\frac{e}{m_i}\right)^2\frac{\partial}{\partial v}\int \delta(\omega_1' - k_1'v)\frac{\partial\Phi}{\partial v}\left|E^{T(1)}_{k_1',\omega_1'}\right|^2 dk_1'\,d\omega_1'. \end{aligned} \tag{16}$$

On the other hand, it is known that[3]

$$\left|E^{T(1)}_{k_1,\omega_1}\right|^2 = \frac{\omega_{pi}^6}{n_0^3 m_i}\frac{1 + 2\xi}{(1 + \xi)^2}I_{k_1,\omega_1}\int \frac{w_{k',\omega'}\,dk'\,d\omega'}{\left|\bar{\varepsilon}(k_1 - k', \omega_1 - \omega')\right|^2}\frac{\left|C_{k',\omega'}\right|^2}{(\omega_1 - \omega')^4}, \tag{17}$$

where

$$\xi = \frac{n_0 m_i}{T_e + T_i}d_2, \quad d_2 = \left(\frac{e}{m_i}\right)^2\frac{\omega_{pi}^2}{n_0}\int \frac{I_{k_1,\omega_1}\,dk_1\,d\omega_1}{\bar{\varepsilon}(k - k_1, \omega - \omega_1)\,\omega_1^2(\omega_1 - \omega)^2}. \tag{18}$$

Using these results, we can compare I_1 and I_2. Using (17) and carrying out the corresponding lengthy but straightforward calculations, we find that I_2 differs by a factor of $(W/nT)(kv_{Te}/\omega)^2(m_e/m_i)^2$ from I_1 in our case. From the condition that the spectral distribution $w_{k,\omega}$ reach a maximum at $\omega/(kv_{Te}) \sim 1$ we find

$$\frac{I_2}{I_1} \sim \frac{W}{nT}\left(\frac{m_e}{m_i}\right)^2 \ll 1.$$

Accordingly, from Eq. (15) we can determine the ion heating rate if we know $w_{k,\omega}$.

3. EQUATION FOR THE CORRELATION FUNCTION FOR LOW-FREQUENCY FLUCTUATIONS

To determine the specific form of $w_{k,\omega}$, which takes account of the nonlinear response of the plasma to a low-frequency perturbation, we must first find $f^{R(2)}_{k,\omega}$, which is a quadratic function of E^R:

$$\begin{aligned} f^{R(2)}_{k,\omega} &= -i\left(\frac{e}{m_i}\right)\frac{1}{\omega - kv}\frac{\partial}{\partial v}\int \left(E^R_{k_1,\omega_1}f^{R(1)}_{k_2,\omega_2} - \left\langle E^R_{k_1,\omega_1}f^{R(1)}_{k_2,\omega_2}\right\rangle\right) \\ &\quad \times \delta(k - k_1 - k_2)\,\delta(\omega - \omega_1 - \omega_2)\,dk_1\,dk_2\,d\omega_1\,d\omega_2 \\ &\quad + \frac{an^{(2)}_{k,\omega}}{\omega - kv}\frac{\partial}{\partial v}(\omega - kv)\frac{\partial\varphi}{\partial v}, \end{aligned} \tag{19}$$

where

$$a = \frac{d_1}{1 + \xi}, \quad d_1 = \left(\frac{e}{m_i}\right)^2\frac{\omega_{pi}^2}{n_0}\int \frac{I_{k_1,\omega_1}\,dk_1\,d\omega_1}{\bar{\varepsilon}(k - k_1, \omega - \omega_1)\,\omega_1(\omega_1 - \omega)^3}. \tag{20}$$

Using the equation $E^R_{k,\omega} = (4\pi ie/k)(n^e_{k,\omega} - n^i_{k,\omega})$ and Eq. (19), after lengthy but straighforward calculations analogous to those of ref. 3, we find an equation for the correlation functions of the low-frequency waves:

$$v_\lambda = v_{\lambda e} + v_{\lambda i},$$

where $v_{\lambda e}$ is the electron correlation function described by Eq. (30) of ref. 3, and

$$v_{\lambda i} = \int\limits_0^\lambda \frac{d\lambda_1}{\lambda_1^4} \int\limits_\lambda^{\lambda_1} \frac{\lambda_1 - \lambda_2}{\lambda_2^4 (\lambda - \lambda_1)(\lambda - \lambda_2)} v_{\lambda_1, k_1} v_{\lambda_2, k_2} d\lambda_2 \tag{21}$$

is the equation for the ion correlation function, where

$$\lambda_i = \frac{\omega}{kv_{Ti}}, \quad \lambda_0^2 = \frac{3W}{4n_0 T_e}, \quad v_{\lambda, k} = \frac{\omega_{pi}^2}{2\pi n_0 m_i v_{Ti}^2} w_{k, \omega}.$$

Let us consider the case $\omega/k < v_{Ti}$ and $\omega_1/k_1 > v_{Ti}$, i.e., the case in which ions interact with electrons with large phase velocities, $\omega/k \gg v_{Te}$. Using the form of the correlation function for the electrons, $v_{\lambda e} \simeq \lambda_e^4/\lambda_0^4$, we seek a solution of Eq. (21) in the form

$$v_{\lambda_i} \simeq \left(\frac{m_e}{m_i}\right)^4 \frac{\lambda_i^4}{\lambda_0^8} = \text{const.} \tag{22}$$

In this case we find $v_{\lambda i} \gg v_{\lambda e}$.

Multiplying Eq. (1) by $(mv^2/2)$, integrating over all velocities, and using the solution of Eq. (21), we find the particle heating rate to be

$$\begin{aligned} \frac{d(n_0 T_i)}{dt} &= \frac{\omega_{pi}^2}{n_0} \int w_{k,\omega} v \delta(\omega - kv) \frac{\partial \Phi^i}{\partial v} dk d\omega dv \\ &\simeq n_0 T_i k_{\max} v_{Ti} \lambda_{i\max} \approx n_0 T_i k_{\max} v_{Te} \frac{v_{Ti}}{v_{Te}}. \end{aligned} \tag{23}$$

Using[3]

$$\frac{k_{\max} v_{Te}}{\omega_{pe}} = \left(\frac{W}{nT_e}\right)^{1/2} \xi',$$

where $\xi' = \sqrt{(m_e/m_i)(T_i/T_e)}$, we find the following estimate for the ion heating rate:

$$\frac{1}{nT_i} \frac{d}{dt}(nT_i) = \frac{v_{Ti}}{v_{Te}} \xi' \left(\frac{W}{nT_e}\right)^{1/2} \omega_{pe}. \tag{24}$$

in other words, the ion heating rate is v_{Ti}/v_{Te} times the electron heating rate.

4. EFFECT OF MODULATED WAVES WITH LOW PHASE VELOCITIES ON THE LINEAR PROPERTIES OF THE CONDENSATE

We turn now to the question of how the linear properties of the condensate are affected by the excitation of modulated waves with $\omega < kv_{Ti}$. In analyzing the linear properties of a condensate of plasmons, we take account only of the response $f^T_{k,\omega}$, which is linear in $E^1_{k,\omega}$. We must first find an equation for the correlation function of the high-frequency fluctuations:

$$\langle E^T_{k,\omega} E^T_{k',\omega'} \rangle_h = I_{k,\omega} \delta(k + k') \delta(\omega + \omega'), \tag{25}$$

where

$$I_{k,\omega} = -\frac{4\pi ie}{k} \int \langle E^T_{k',\omega'} f^T_{k,\omega} \rangle dk' d\omega' dv. \tag{26}$$

Now we expand all the quantities $E^T_{k,\omega}$ and $f^T_{k,\omega}$ in series in E^R and retain only the linear terms:

$$E^T_{k,\omega} = E^{T(0)}_{k,\omega} + E^{T(1)}_{k,\omega}, \quad f^T_{k,\omega} = f^{T(0)}_{k,\omega} + f^{T(1)}_{k,\omega}, \tag{27}$$

where "(0)" and "(1)" designate the ground turbulent state and the deviation from it.

Using the following equation[4] for $f^{T(0)}_{k,\omega}$,

$$f^{T(0)}_{k,\omega} = -i \frac{e}{m_i} \frac{E^{T(0)}_{k,\omega}}{\omega - kv} \frac{\partial \Phi^i}{\partial v}, \tag{28}$$

and substituting it into (20), we find

$$\varepsilon_{k,\omega} I_{k,\omega} = 0, \tag{29}$$

where

$$\varepsilon_{k,\omega} = 1 + \frac{\omega_{pi}^2}{n_0 k} \int \frac{1}{\omega - kv} \frac{\partial \Phi^i}{\partial v} dv \approx 1 + \frac{\omega_{pi}^2}{k^2 v_{Ti}^2}$$

is the ordinary linear dielectric constant.

However, in (28) we have taken account only of the linear functional dependence; we have neglected the effect of low-frequency modulated waves.

We now take into account the effects of low-frequency modulated waves:

$$\begin{aligned} \delta f^{T(0)}_{k,\omega} = &-i\left(\frac{e}{m_i}\right) \frac{1}{\omega - kv} \frac{\partial}{\partial v} \int \left(E^{T(1)}_{k_1,\omega_1} f^{R(1)}_{k_2,\omega_2} + E^R_{k_2,\omega_2} f^{T(1)}_{k_1,\omega_1}\right) \\ &\times \delta(k - k_1 - k_2) \delta(\omega - \omega_1 - \omega_2) dk_1 dk_2 d\omega_1 d\omega_2 \end{aligned} \tag{30}$$

and

$$\begin{aligned} f^{T(1)}_{k,\omega} = &-i \frac{e}{m_i} \frac{E^{T(1)}_{k,\omega}}{\omega - kv} \frac{\partial \Phi}{\partial v} - i \frac{e}{m_i} \frac{1}{\omega - kv} \frac{\partial}{\partial v} \int \left(E^{T(0)}_{k_1,\omega_1} f^{R(1)}_{k_2,\omega_2} + E^R_{k_1,\omega_1} f^{T(0)}_{k_2,\omega_2}\right) \\ &\times \delta(k - k_1 - k_2) \delta(\omega - \omega_1 - \omega_2) dk_1 dk_2 d\omega_1 d\omega_2 \end{aligned}$$

or

$$\delta f^{T(0)}_{k,\omega} = -\frac{4\pi e^2}{m_i^2} \frac{1}{\omega - kv} \frac{\partial}{\partial v} \int \frac{w_{k_1,\omega_1} dk_1 d\omega_1}{\omega - \omega_1 - (k - k_1) v} \frac{\partial f^{T(0)}_{k,\omega}}{\partial v} -$$

$$-\left(\frac{e}{m_i}\right)^2\frac{1}{\omega-kv}\frac{\partial}{\partial v}\int\frac{1}{\omega-\omega_1-(k-k_1)v}\frac{\partial}{\partial v}\left\langle E^R_{k_1,\omega_1}E^{T(0)}_{k_2,\omega_2}f^{R(1)}_{k_3,\omega_3}\right\rangle_l$$
$$\times\,\delta(k-k_1-k_2-k_3)\,\delta(\omega-\omega_1-\omega_2-\omega_3)\,dk_1dk_2dk_3d\omega_1d\omega_2d\omega_3$$
$$-\,i\left(\frac{e}{m_i}\right)\frac{1}{\omega-kv}\frac{\partial}{\partial v}\int\left\langle E^{(T(1)}_{k,\omega}\left(f^{R(1)}_{k_2,\omega_2}-i\frac{e}{m_i}\frac{E^R_{k_2,\omega_2}}{\omega_1-k_1v}\frac{\partial\Phi}{\partial v}\right)\right\rangle_l$$
$$\times\,\delta(k-k_1-k_2)\,\delta(\omega-\omega_1-\omega_2)\,dk_1dk_2d\omega_1d\omega_2, \qquad (32)$$

where w_{k_1,ω_1} is the correlation function for low-frequency waves, introduced in the equation

$$\langle E^R_{k,\omega}E^R_{k',\omega'}\rangle_l = 4\pi w_{k,\omega}\delta(k+k')\delta(\omega+\omega'). \qquad (33)$$

Now substituting (32) into (26) and setting $E^T_{k,\omega} = E^{T(0)}_{k,\omega}$, we find the corrections to the linear part of the dielectric constant due to the effect of modulated waves. The correction due to the first two terms in (32) is small because $W/nT \ll 1$, as in ref. 3.

The basic change comes from the third term in (32), which makes the following contribution to the right side of (26):

$$-\frac{4\pi e^2}{m_i^2k}\int\frac{dv}{\omega-kv}\left\langle\!\left\langle E^{T(0)}_{k',\omega'}E^{T(1)}_{k_1-k',\,\omega_1'-\omega'}\right\rangle_h\frac{\partial}{\partial v}\left(f^{R(1)}_{k_2,\omega_2}-i\frac{e}{m_i}\frac{E^R_{k_2,\omega_2}}{\omega_1-k_1v}\frac{\partial\Phi}{\partial v}\right)\right\rangle_l$$
$$\times\,\delta(k-k_2-k_1'+k')\,\delta(\omega-\omega_2-\omega_1'+\omega')\,dk_1dk_2dk'd\omega'd\omega_1d\omega_2. \qquad (34)$$

Neglecting the second term because of the large quantity $\omega-\omega_2$, using the value $\langle E^{T(0)}_{k',\omega'}E^{T(1)}_{k_1'-k',\omega_1'-\omega'}\rangle_h$ from ref. 3, and assuming $f^{R(1)}_{k,\omega}$ to be a linear function of E^R, we find the following equation from (26) for the correction to the dielectric constant which takes account of the modulated waves:

$$\varepsilon^R_{k,\omega}=\frac{\omega^2_{pi}}{n_0^3m_i}\int|C_{k',\omega'}|^2\frac{w_{k',\omega'}dk'd\omega'}{\tilde{\varepsilon}(k-k',\,\omega-\omega')}, \qquad (35)$$

where

$$C_{k',\omega'}=\int\frac{1}{\omega'-k'v}\frac{\partial\Phi^i}{\partial v}dv. \qquad (36)$$

We see from Eq. (35) that the absorption of plasma waves is due to only the imaginary part of $1/\tilde{\varepsilon}(k-k',\,\omega-\omega')$. As in the case of electrons, when we neglect the nonlinear correction to $\tilde{\varepsilon}$, we find that the damping of the condensate is due to a wave resonance of the condensate plasmons and modulation waves.

5. DISCUSSION OF RESULTS

The results found here can be compared with the heating of plasma ions observed experimentally under beam−plasma interaction conditions in Q machines.[5] According to ref. 5, we have a ratio $T_i/T_e \simeq 0.1$-0.25 at various electron temperatures. Calculations based on the equation

$$\frac{T_e}{T_i}=(\omega_{pe}t)^2\frac{W}{nT_e}\left(\frac{m_e}{m_i}\right)\xi'^2 \qquad (37)$$

for a turbulence energy level[5] of $W/(nT_e) = 10^{-2}$-10^{-3}, for the value $\xi' \simeq 10^{-4}$, and under the assumption $t = L/v_{Ti}$, (where L is the length of the apparatus) lead to

$$\frac{T_i}{T_e}\simeq 0.2.$$

We see that the theoretical result agrees satisfactorily with experiment.

In conclusion the author thanks V. N. Tsytovich for interest in this work and for discussion of these results.

Plasma

Surface waves in a magnetized plasma in a radio-frequency field

E. E. Lovetskii and A. N. Starodub

Moscow Engineering-Physics Institute

(Submitted February 8, 1973)
Zh. Tekh. Fiz., 44, 508-513 (March 1974)

The effect of an external radio-frequency electric field (rf field) on the surface waves of a magnetized plasma is analyzed. A strong rf field can lead to stabilization or to a change in the growth region. The parametric excitation of low-frequency surface waves by an rf field is analyzed.

When a plasma is confined by an external magnetic field, surface waves can exist and grow at the plasma–vacuum boundary.[1,2] The basic mechanism for the growth of these waves is charge convection in the field of the wave; this phenomenon is very important in low-frequency waves, i.e., frequencies below the ion plasma frequency. It has been shown that crossing of the magnetic lines of force does not always effectively stabilize surface waves. For this reason we turn to an analysis of the possibility of suppressing surface-wave instabilities by an rf electric field. Electron oscillations in an rf field lead to spatial dispersion, which is one of the mechanisms by which an rf field affects plasma waves. Fainberg and Shapiro[3] analyzed the effect of an rf field on plasma drift waves with wavelengths small in comparison with the characteristic scale of the inhomogeneity; they found that a strong rf field stabilizes oscillations with $\omega \gg k_z v_{Te}$ and changes the instability region for frequencies $\omega \ll k_z v_{Te}$. The effect of an rf field on the low-frequency surface-wave spectra is similar.

It is known that an rf field can parametrically excite surface waves in a plasma.[4,5] Below we focus on the resonant interaction of an rf field with surface waves. We find that under these conditions surface waves can grow rapidly, with growth rates exceeding the ion plasma frequency.

1. We consider electrostatic surface waves of a plasma at its interface with a vacuum. The plane boundary is perpendicular to the x axis. The plasma is in a fixed, homogeneous magnetic field **B** and an rf electric field $\mathbf{E}(t) = \mathbf{E}_0 \sin \omega_0 t$, both of which are parallel to the plasma boundary, along the z axis. We assume that in the region of the smeared-out boundary the plasma is slightly inhomogeneous, i.e., that the Larmor radii of the particles are small in comparison with the characteristic dimension of the plasma inhomogeneity, L. For a slightly inhomogeneous plasma we can use the standard procedure of solving the kinetic equations and obtain the Poisson equation in the following form for the Fourier coefficients of the electric potential:

$$\Delta\Phi_s = \sum_{n,\,p=-\infty}^{\infty} \int dk_x e^{ik_x x} \Phi_p(k_x) M(k_x,\ x,\ \omega_n) J_{n-s}(\mu) J_{n-p}(\mu), \quad (1)$$

where the kernel $M(k_x, x, \omega_n)$ differs from that found in ref. 6 by the replacement $\omega \to \omega_n = \omega + n\omega_0$, $J_p(\mu)$ is the Bessel function with argument $\mu = k_z E_0/\omega_0^2\,(e_i/M + e/m)$, and the electric potential is written in the form $\Phi = \sum_{s=-\infty}^{\infty} \Phi_s \cdot e^{-i(\omega + s\omega_0)t}$. A summation over the different types of particles is also carried out in Eq. (1).

The wavelength of the surface waves is large in comparison with the characteristic scale of the inhomogeneity and even larger in comparison with the Larmor radii of the particles. Under these conditions, integrodifferential equation (1) reduces to a second-order differential equation for Φ_s.

According to the standard procedure for obtaining the dispersion relation for surface waves, we should substitute the solutions of the Poisson equation in the homogeneous regions on the two sides of the boundary into the boundary conditions. We find the boundary conditions on the potential by integrating the Poisson equation along x in the inhomogeneous region. The dispersion relation is found by setting the following determinant equal to zero:

$$\left| \delta_{np} - \frac{\Delta\varepsilon_{in}}{1+\Delta\varepsilon_{in}} \sum_q \frac{\Delta\varepsilon_{eq}}{1+\Delta\varepsilon_{eq}} J_{p-q}(\mu) J_{n-q}(\mu) \right| = 0, \quad (2)$$

where

$$\Delta\varepsilon_n = \frac{1}{2(\varkappa + k_0)} \frac{\omega_L^2}{\Omega^2} \left\{ \varkappa + \left(\varkappa + 2k_y \frac{\Omega}{\omega_n}\right) J_+\left(\frac{\omega_n}{|k_z| v_T}\right) \right.$$
$$\left. - \omega_n \left[\frac{\varkappa + k_y}{\omega_n - \Omega} J_+\left(\frac{\omega_n - \Omega}{|k_z| v_T}\right) + \frac{\varkappa - k_y}{\omega_n + \Omega} J_+\left(\frac{\omega_n + \Omega}{|k_z| v_T}\right) \right] \right\},$$
$$J_+(x) = x e^{-x^2/2} \int_{i\infty}^{x} d\tau e^{\tau^2/2}, \quad \omega_L^2 = \frac{4\pi N e^2}{m}, \quad \Omega = \frac{eB}{mc},$$

and $k_0^2 = k_y^2 + k_z^2$. The quantity $\varkappa$, which represents the reciprocal of the wavelength in the homogeneous region, is defined by

$$\left| \delta_{np} - \frac{\Delta\sigma_{in}}{1+\Delta\sigma_{in}} \sum_q \frac{\Delta\sigma_{eq}}{1+\Delta\sigma_{eq}} J_{p-q}(\mu) J_{n-q}(\mu) \right| = 0, \quad (3)$$

where

$$\Delta\sigma_n = \frac{\omega_L^2}{v_T^2(\varkappa^2 - k_0^2)} \left[J_+\left(\frac{\omega_n}{|k_z| v_T}\right) - 1 \right]$$
$$+ \frac{\varkappa^2 - k_y^2}{\varkappa^2 - k_0^2} \frac{\omega_L^2}{\Omega^2} \left[J_+\left(\frac{\omega_n}{|k_z| v_T}\right) - \frac{\omega_n}{\omega_n - \Omega} J_+\left(\frac{\omega_n - \Omega}{|k_z| v_T}\right) - \frac{\omega_n}{\omega_n + \Omega} J_+\left(\frac{\omega_n + \Omega}{|k_z| v_T}\right) \right].$$

Solving system (2), (3), we can analyze the surface waves of a magnetized plasma in an rf field. If we assume $\omega_0 \gg \omega_{Li}, \Omega_i$, we can simplify system (2), (3), finding

$$\left. \begin{aligned} 1 - \frac{\Delta\varepsilon_{i0}}{1+\Delta\varepsilon_{i0}} \sum_n \frac{\Delta\varepsilon_{en} J_n^2}{1+\Delta\varepsilon_{en}} = 0, \\ 1 - \frac{\Delta\sigma_{i0}}{1+\Delta\sigma_{i0}} \sum_n \frac{\Delta\sigma_{en} J_n^2}{1+\Delta\sigma_{en}} = 0. \end{aligned} \right\} \quad (4)$$

We will analyze this system of equations for two frequency ranges of the surface waves. When $\omega \lessgtr \omega_{Li}$, surface waves of the magnetized plasma can grow in the absence of an external rf field. We therefore turn to the stabilizing effect of the rf field for such waves. Furthermore, surface waves can be parametrically excited by an external rf field. We consider the parametric effect of an rf field on high-frequency surface waves ($\omega \gg \omega_{Li}$) which are stable in the absence of an rf field.

2. The analysis of the stabilizing effect of the rf field on the low-frequency surface waves ($\omega \lesssim \omega_{Li}$) is simplified considerably if the frequency of the rf field is higher than that used in deriving Eqs. (4): $\omega_0 \gg \omega_{Li}^2/\Omega_i, k_z v_{Te} \cdot (\omega_{Li}/\Omega_i)$. This situation corresponds primarily to the case of a dense plasma, with $\omega_{Li} \gg \Omega_i$. In a low-density plasma, we require $\omega_0 \gg k_z V_{Te}$. Furthermore, the plasma densities are limited from above by the condition $\omega_{Le} \ll \Omega_e$. Then we are left with only the n = 0 terms in the sums of Eqs. (4).

We begin the analysis of Eqs. (4) simplified in this manner with the case in which the electron thermal velocity is large in comparison with the plane velocity of the waves, i.e., when $\omega \ll k_z v_{Te}$. In this frequency range, growing ion-acoustic surface waves can exist in the absence of an rf field.[1,2] The rf field modifies the wave spectra slightly and the conditions under which the waves exist.

In a dense plasma, $\omega_{Li} \gg \Omega_i$, surface ion-acoustic waves can exist only in the nonisothermal case $T_e \gg T_i$ at a frequency $\omega \lesssim \Omega_i$ under the condition $k_y > k_z \gg k_y \cdot (m/M)^{1/2}$. The presence of an rf field can change this latter condition: If the field is so strong that $1-J_0^2 \simeq 1$, this condition becomes $k_z \gg k_y\,(\omega_{Le}/\Omega_e)$. The spectrum of surface ion-acoustic waves in the presence of an rf field is

$$\left.\begin{aligned}\omega^2 &= \frac{1}{2}\{k_0^2 v_s^2 + \Omega_i^2 + \omega_{Li}^2(1-J_0^2)\\ &\pm \sqrt{[k_0^2 v_s^2 + \Omega_i^2 + \omega_{Li}^2(1-J_0^2)]^2 - 4k_0^2 v_s^2 \Omega_i^2}\},\\ \gamma &= \sqrt{\frac{\pi}{2}}\frac{\omega^2}{|k_z| v_{Te}}\frac{\Omega_i^2-\omega^2}{k_0^2 v_s^2 \Omega_i^2 - \omega^4}\left\{k_0^2 v_s^2 - \frac{\omega^2}{2}\left[1 + \frac{\omega_{Li}^2}{\omega^2-\Omega_i^2}(1-J_0^2)\right.\right.\end{aligned}\right\} \quad (5)$$

where $v_s^2 = T_e/M$. It follows from (5) that an external rf field does not stabilize surface ion-acoustic waves, but it can significantly change the shape of the spectrum. In particular, under the condition $\omega_{Li}^2(1-J_0^2) \gg \Omega_i^2$, we can write (5) as

$$\omega^2 = \frac{k_0^2 v_s^2 \Omega_i^2}{k_0^2 v_s^2 + \omega_{Li}^2(1-J_0^2)}, \quad \gamma = \sqrt{\frac{\pi}{8}}\frac{\omega^2}{|k_z| v_{Te}}\frac{k_0^2 v_s^2(\Omega_i^2-\omega^2)}{k_0^2 v_s^2 \Omega_i^2 - \omega^4}. \qquad (6)$$

In a low-density plasma with $\omega_{Li} \ll \Omega_i$, growing surface ion-acoustic waves can also exist. The frequency of these waves is low in comparison with the ion gyrofrequency and is given by

$$\omega = -\frac{k_y \omega_{Li}^2}{|k_y| \Omega_i \left[1 + \left(1 + \frac{\omega_{Li}^2}{k_y^2 v_s^2}\right)^{1/2}\right]}, \quad \gamma = \sqrt{\frac{\pi}{2}}\frac{\omega^2}{|k_z| v_{Te}} J_0^2. \qquad (7)$$

These waves can exist under the conditions

$$k_y \frac{\omega_{Li}}{\Omega_i} \gg k_z \gg \frac{k_y \omega_{Li}^2}{|k_y| v_{Te} \Omega_i \left[1 + \left(1 + \frac{\omega_{Li}^2}{k_y^2 v_s^2}\right)^{1/2}\right]} \text{ and } \frac{T_i}{T_e} \ll \frac{\Omega_i^2}{\omega_{Li}^2}.$$

The first of these conditions holds for $k_y v_{Te} \gg \omega_{Li}$; it follows from the second condition that the waves can occur even in an isothermal plasma. The growth rate of the waves falls off with increasing rf fields.

We turn now to the range of wave frequencies which are considerably higher than the ion gyrofrequency but which still satisfy $\omega \lesssim \omega_{Li}$. Surface waves exist in this frequency range in a highly nonisothermal plasma under the condition $T_i/T_e \ll \Omega_i^2/\omega_{Li}^2$; their spectrum can be conveniently found for the two limiting cases $k_y v_s \gg \omega_{Li}$ and $k_y v_s \ll \omega_{Li}$.

If $k_y v_s \gg \omega_{Li}$, we have

$$\omega^2 = \frac{\omega_{Li}^2}{2}\left[1 - \frac{a(a+1)}{a^2+1} J_0^2\right], \qquad (8)$$

where

$$a = \sqrt{\frac{\pi}{8}}\frac{k_y}{|k_y|}\frac{\omega_{Li}^2}{|k_z| v_{Te} \Omega_i}.$$

An increase in the amplitude of the rf field reduces the growth rate of the waves in (8).

If $k_y v_s \ll \omega_{Li}$, the surface-wave spectrum has the following form:

$$\omega^2 = \omega_{Li}^2 \frac{1 + b(1-J_0^2)}{1+b}, \quad \gamma \sqrt{\frac{\pi}{8}}\frac{\omega_{Li}^2}{|k_z| v_{Te}}\frac{bJ_0^2}{(1+b)^2}, \qquad (9)$$

where

$$b = \frac{\pi}{2}\frac{k_y^2}{k_z^2}\frac{\omega_{Le}^2}{\Omega_e^2}.$$

An increase in the amplitude of the rf field can lead to a stabilization of waves (9), as in the case of spectrum (8).

We turn now to surface waves in the case in which the electron thermal velocity is lower than the phase velocity of the waves, i.e., $\omega \gg k_z v_{Te}$. The frequency of these waves must be small in comparison with the ion gyrofrequency.

We first assume a dense plasma: $\omega_{Li} \gg \Omega_i$. If $\varkappa = |k_y|$, and if $\alpha \gg \Omega_i^2/(k_y^2 v_s^2)$, where

$$\alpha = \frac{k_y}{|k_z|}\left(\frac{m}{M}\right)^{1/2},$$

the dispersion relation becomes

$$\omega^3 - \omega\frac{\omega_{Li}^2}{2}(1-J_0^2) - \frac{k_y}{|k_y|} k_z^2 v_{Te}^2 \Omega_i = 0, \qquad (10)$$

from which we see that unstable solutions are possible only when the electron thermal motion is taken into account, for which case the condition

$$12\sqrt{3}\, k_z^2 v_{Te}^2 \Omega_i \gg \omega_{Li}^2 \mu^3 \qquad (11)$$

must hold.

The maximum growth rate of the waves is of order $(k_z^2 v_{Te}^2 \Omega_i)^{1/3}$. If the condition opposite to (11) holds, the plasma is stable because of the influence of the rf field. The critical amplitude of the rf field – above which these waves do not grow – is

$$\frac{m\omega_0^2}{ek_z\omega_{Li}}\left(12\sqrt{3}k_z^2v_{Te}^2\Omega_i\right)^{1/3}.$$

If α is much smaller than $[\Omega_i/(k_yv_s)]^2$ but still large, we have the following surface-wave spectrum:

$$\omega^2=-i\frac{\alpha k_z^2v_{Te}^2}{1+\alpha^2\frac{\omega_{Li}^2}{\Omega_i^2}(1-J_0^2)}. \tag{12}$$

It follows from this expression that the waves become stabilized by the external rf field under the condition $\alpha(\omega_{Li}^2/\Omega_i^2)(1-J_0^2) \gtrsim 1$, i.e., when the field amplitude reaches

$$E_0\sim\frac{m\omega_0^2\Omega_i}{ek_z\omega_{Li}}\left(\frac{2}{\alpha}\right)^{1/2}.$$

For a low-density plasma, $\omega_{Li} \ll \Omega_i$, we consider two possibilities: First, if $\varkappa = |k_y|$, i.e., if $\alpha \gg \Omega_i\omega_{Li}/(k_y^2v_s^2)$, the dispersion relation is

$$\omega^3-\frac{\omega}{4}\frac{\omega_{Li}^4}{\Omega_i^2}(1-J_0^2)-\frac{1}{2\Omega_i}k_z^2v_{Te}^2\omega_{Li}^2=0. \tag{13}$$

This equation has a solution corresponding to growth under the condition $12\sqrt{6}k_z^2v_{Te}^2 > (\omega_{Li}^4/\Omega_i^2)\mu^3$. The maximum growth rate of the waves in this case turns out to be on the order of $(k_z^2v_{Te}^2\omega_{Li}^2/\Omega_i)^{1/3}$. The waves are stabilized when the rf field exceeds an ampltitude

$$\frac{m\omega_0^2}{ek_z}\left(12\sqrt{6}\frac{k_z^2v_{Te}^2\Omega_i^2}{\omega_{Li}^4}\right)^{1/3}.$$

Second, if $\alpha \ll \omega_{Li}\Omega_i(k_y^2v_s^2)$ but $\alpha \gg \Omega_i/\omega_{Li}$, the plasma is unstable with respect to the excitation of surface waves having the spectrum

$$\omega^2=-i\frac{\omega_{Li}}{\Omega_i}\frac{\alpha k_z^2v_{Te}^2}{1+\alpha^2\frac{\omega_{Li}^2}{\Omega_i^2}(1-J_0^2)}. \tag{14}$$

If the amplitude of the external rf field reaches the order of $m\omega_0^2/(ek_z)(\Omega_i/\alpha\omega_{Li})^{1/2}$, the waves in (14) are stabilized, since a condition for their existence, $\omega \gg k_zv_{Te}$ is violated.

3. We turn now to the question of a parametric excitation of surface waves in a magnetized plasma by an external rf field. In the absence of an external field, there is a parametric buildup[4] of surface waves in a cold plasma at the resonance frequency $\omega_{Le}/\sqrt{2}$. In a magnetized plasma, with $\Omega_e^2 \gg \omega_{Le}^2$, we can determine the resonant frequency $\omega_r = (\omega_{Li}^2/\Omega_i)(k_y/k_0+\varkappa)$ from the first equation in (4). As the external frequency ω_0 or its harmonic $n\omega_0$ approaches the resonant frequency, the n-th term in dispersion relation (4) increases in magnitude and can become much higher than the other terms of the series, with the possible exception of the zeroth term. Here the dispersion relation simplifies considerably, since only the zeroth and n-th terms are retained in the sum.

We first consider surface waves having a frequency $\omega \gg \omega_{Li}, \Omega_i$. For such frequencies it follows from the second equation in (4) that

$$\varkappa^2=k_0^2+\frac{\omega_{Li}^2}{v_s^2}\left[1-J_+\left(\frac{\omega}{|k_z|v_{Te}}\right)\right]. \tag{15}$$

The corresponding dispersion relation can be written

$$\omega^3-n\omega_0\xi_n\omega^2+\frac{\varkappa}{k_y}\Omega_i\omega_r^2J_n^2=0, \tag{16}$$

where the detuning is $\xi_n = (\omega_r/n\omega_0)-1$. Among the solutions of this equation are those corresponding to the most intense, aperiodic growth. Let us consider the case in which $\varkappa$ is not a function of ω; this is true at freqeuncies $\omega \ll k_zv_{Te}$ if $\varkappa = (k_0^2+\omega_{Li}^2/v_s^2)^{1/2}$ and at frequencies $\omega \gg k_zv_{Te}$ if $\varkappa = |k_y|$, if $k_y \gg k_z(\omega_{Le}/\omega)$. We find two spectra from Eq. (16), depending on the magnitude of the detuning. At a slight detuning, $(n\omega_0\xi_n)^3 \ll (\varkappa/k_y)\Omega_i\omega_r^2J_n^2$, we have a cubic spectrum,

$$\omega^3=-\frac{\varkappa}{k_y}\Omega_i\omega_r^2J_n^2, \tag{17}$$

while if the opposite condition holds we have a spectrum

$$\omega=\frac{\varkappa\Omega_i\omega_r^2J_n^2}{k_yn\omega_0\xi_n}. \tag{18}$$

It is crucial for the growth of waves (18) that the signs of k_y and ξ_n be opposite.

Furthermore, there is a possible immediate parametric buildup of two surface waves. We illustrate this situation with the example of waves at frequency $\omega \ll \omega_{Li}, \Omega_i, k_zv_{Te}$ in a dense plasma $\omega_{Li} \gg \Omega_i$. If the frequency of the external field satisfies $\omega_0 \gg k_zv_{Te}(\omega_{Li}/\Omega_i)$ the quantity $\varkappa$ satisfies

$$\varkappa^2=k_0^2+\frac{\Omega_i^2}{v_s^2}\left(1+i\sqrt{\frac{\pi}{2}}\frac{\omega}{|k_z|v_{Te}}\right)\left[1+\frac{\omega_{Li}^2}{\Omega_i^2}(1-J_0^2)\right]. \tag{19}$$

Under these conditions the dispersion relation splits into two factors, one of which corresponds to ion-acoustic surface waves, discussed above, and the other of which can be written as

$$1-i\sqrt{\frac{\pi}{2}}\frac{\omega_rJ_0^2}{|k_z|v_{Te}}-\frac{\omega_rJ_n^2}{\omega-n\omega_0\xi_n}=0. \tag{20}$$

We find the frequency

$$\omega=n\omega_0\xi_n+\omega_rJ_n^2 \tag{21}$$

and the growth factor

$$\gamma=\sqrt{\frac{\pi}{2}}\frac{\omega_r^2}{|k_z|v_{Te}}\left[J_0^2J_n^2-\frac{(1+J_n^2)(\xi_n+J_n^2)}{2\varkappa(\varkappa+k_0)}\right] \tag{22}$$

for the surface waves which are excited by the rf field at the same time as waves corresponding to the resonant frequency. Equations (21) and (22) contain only the real part of $\varkappa$.

The authors thank Yu. M. Aliev and O. M. Gradov for discussion.

Magnetic field in a θ pinch with an axial conductor

Ya. F. Volkov, V. G. Dyatlov, and N. I. Mitina
Physicotechnical Institute,
Academy of Sciences of the Ukrainian SSR, Khar'kov

(Submitted April 13, 1973; resubmitted August 3, 1973)
Zh. Tekh. Fiz., 44, 514-518 (March 1974)

For the presence near the axis of a θ pinch of a magnetic flux, of an inverse external flux, magnetic lines of force near the axis of an azimuthal plasma current form a system of closed concentric lines. With the application of an azimuthal magnetic field the lines of force form toroidal magnetic surfaces whose major axis is the axis of the θ-pinch system. The aim of the present work is to experimentally investigate the principal parameters formed in the discharge of closed magnetic configurations. The basic investigation method is probe magnetic measurements. Using the Maxwell equation curl $H = (4\pi/c)j$, we obtain the topography of the azimuthal plasma current. To analyze the structure of the magnetic field we numerically integrate the equation of magnetic lines of force $dr/B_r = dz/B_z = r d\varphi/B_\varphi$, where B_r, Bz, and B_φ are the magnetic-field components, the z axis is the axis of the θ-pinch system. In a θ-pinch system with an applied azimuthal field there exist Tokamak-type toroidal magnetic configurations. The magnetic-surface cross sections are extended along the axis of the system. The characteristic dimensions of the cross sections are of the order of the major radius of the surfaces. This facilitates obtaining a sufficient margin of stability, which in the experiment is $q \approx 6$. The system has mean minimum B of the order of several tens of percent and shear of about $S \approx 0.4$. The time of existence of the given configuration is determined by the period of the discharge ($T = 30 = 30$ μsec) and is about 7 μsec.

With a reverse flux near the axis of a θ pinch, the magnetic lines of force near the axis of an azimuthal plasma current form a system of closed concentric lines, with centers on the current axis. If an azimuthal magnetic field is applied to such a θ pinch, the lines of force become helical lines which lie on toroidal surfaces, the major axis being the axis of the θ-pinch system. Such a magnetic configuration is topologically similar to Tokamak configurations. The azimuthal plasma current of the θ pinch corresponds to the main plasma current in the Tokamak, and the azimuthal field corresponds to the toroidal field.

A toroidal magnetic field produced by a quasistationary current through a rod along the axis of the θ-pinch system was first used to stabilize a discharge.[1] Similar systems have been subsequently studied from the point of view of plasma confinement.[2-4]

In the production of a Tokamak-type magnetic configuration the ratio between the magnetic field of the induced current and the primary θ-pinch current is highly important. The magnitude of the plasma current should be such that inside the plasma ring the total magnetic flux due to the θ pinch and the current should be in the direction opposite to that of the external flux. This is possible only with an initial reverse flux. For this purpose we use an initial external reverse field[2] or a specially constructed current-carrying rod[4] in which the current through helical windings located on the rod surface produces the necessary magnetic-field component. In the system being studied here the necessary ratio of magnetic fields is obtained as a result of the reverse magnetic flux maintained inside the plasma ring by the preceding half-period of the discharge.[5]

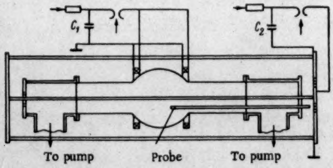

Fig. 1. Schematic diagram of apparatus. $C_1 = 60$ μF is the capacitor bank supplying the coils of the B_z field; $C_2 = 3000$ μF is the capacitor bank supplying the rod.

The aim of the present work is to investigate experimentally the parameters of a θ pinch with an applied azimuthal magnetic field, when the system is used as a closed magnetic configuration.

APPARATUS AND METHODS

The investigations are carried out on the apparatus shown in Fig. 1. This is a θ pinch with period $T = 30$ μsec and magnetic field $B_{z0} = 12$ kG. The quasistationary ($T = 600$ μsec) current in the rod $I_z = 6 \cdot 10^4$ A. The diameter of the glass discharge chamber is $D = 22$ cm. The working gas is helium at $p = (5\text{-}8) \cdot 10^{-3}$ mm Hg. The mean plasma density is 10^{14}-10^{15} cm^{-3}.

The principal measurements make use of magnetic probes. The probe consists of two search coils 3.5 mm in diameter, oriented in mutually perpendicular planes so that one of them records the axial component and the other, the radial or azimuthal component of the magnetic field as a function of orientation (cylindrical coordinate system). The coils are insulated from the plasma by a 5-mm diam. glass tube. The probe can be moved along the axis and along the radius.

Using the magnetic measurements we calculated the topography of plasma currents using Maxwell's equation with small displacement current:

$$\text{curl } \mathbf{H} = \frac{4\pi}{c} \mathbf{j}.$$

For systems in which the principal part of the magnetic flux is caused by plasma currents, the introduction of a probe unavoidably causes a disturbance in the current structure, which affects the accuracy of the method.

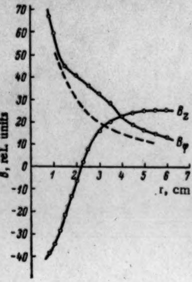

Fig. 2. Distribution of axial B_z and azimuthal B_φ components of magnetic field along radius in central plane of system (z = 0). Dashed curve) the function $B \sim 1/r$ ($B_{z_0} = 12$ kG, $I_z = 6 \cdot 10^4$ A, $p_0 = 6 \cdot 10^{-3}$ mm Hg, t = 2.7 μsec after origin of the vacuum B_z field).

Under the most favorable conditions, we are able to distinguish the separate details of the distribution of currents with characteristic dimension equal to the probe dimension.[6] Estimates show that the mean free path does not exceed the dimensions of the plasma structure. This gives us confidence that the distortions introduced by the probe are not so large as to cause significant variations in the current structure.

The errors in the magnetic-field measurement are below 15%, and the error in numerical methods is less than 1%.

RESULTS

We determine the axial, radial, and azimuthal magnetic-field components as functions of coordinates and time, assuming axial symmetry of the fields.

The results confirm the existence, inside the plasma ring, of sizable trapped fields, the lifetime of which is 5-7 μsec. The radial distribution of the axial field differs principally from the vacuum field. There is also some increase in azimuthal component in the cross section of the plasma ring (Fig. 2).

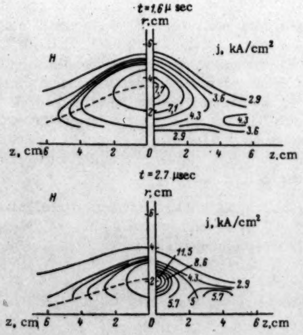

Fig. 3. Cross sections of magnetic surfaces (left) and lines of equal current density (right). $B_{z_0} = 12$ kG, $I_z = 6 \cdot 10^4$ A, $P_0 = 6 \cdot 10^{-3}$ mm Hg.

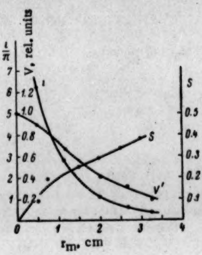

Fig. 4. Dependence of twist angle of lines of force i of specific volume V' and shear S on mean radius of cross section of magnetic surface. $B_{z_0} = 12$ kG, $I_z = 6 \cdot 10^4$ A, $p_0 = 6 \cdot 10^{-3}$ mm Hg.

Knowing the experimental dependences of the magnetic-field components of the coordinates, we can analyze the magnetic-field structure, using the equation of the magnetic lines of force:

$$\frac{dr}{B_r} = \frac{dz}{B_z} = \frac{r d\varphi}{B_\varphi},$$

where the z axis is the axis of the θ pinch. The first two terms give an equation for the cross sections of the magnetic surfaces. Results of numerical integration of this equation are shown in Fig. 3. The cross sections of magnetic surfaces near the magnetic axis ($B_z = B_r = 0$) are nearly elliptical. With increasing distance from the axis they become extended along the z axis so that the cross sections of the peripheral surfaces become larger, like segments of circles with secant parallel to the z axis. The numerical analysis carried out on the behavior of the lines of force on the magnetic surface indicates that it is possible to estimate values of the rotational transform, of the lines of force i, shear S, and specific volume V'. The results are shown in Fig. 4. Near the last closed surface the rotational transform $i \approx 0.3\pi$, which corresponds to a stability margin $q = 2\pi/i \approx 6$. Near the magnetic axis we have $q < 1$.

Variation of the rotational transform confirms the presence of shear. Near the axis the shear is equal to zero; it reaches a maximum value of S = 0.4 at the boundary surface.

The specific volume V' is a maximum on the magnetic axis and decreases as the magnetic surface approaches the boundary surface. This indicates the existence of minimum B or a so-called magnetic well near the axis. The well reaches values 80 ± 45%. We note that in the given case minimum B occurs only on the average. On external sections of the magnetic surfaces an "antiwell" exists.

An important characteristic of the discharge is the magnitude and distribution of the plasma current. Figure 3 shows lines of equal current density. The values of current density are obtained from the magnetic measurements. The current axis is displaced inward with respect to the magnetic axis. The total azimuthal current reaches a value of 50 kA.

We should note the splitting of the lines of equal current density and the appearance of two additional current axes, symmetric with respect to the central plane. These axes lie in regions where $B_z = 0$. It is possible for the minimum-B condition to be satisfied here; this contributes toward the confinement of the plasma in this region.

The noncircular shape of the cross sections of the magnetic surfaces is worth noting. In this case the satisfaction of the stability criterion[7,8] is facilitated. This allows us to attain sizable plasma currents for comparatively small stabilizing fields. In our case a current of order 50 kA is reached with a stabilizing B_φ field of the order of the current field ($\sim$10 kG).

We note that in the absence of a toroidal field the plasma current in the investigated regime is less than 10-15 kA. It lasts for 1-1.5 μsec. Considerable fluctuations in current are observed, which indicates the presence of an instability.

DISCUSSION

Thus, closed magnetic surfaces exist in a θ pinch with an applied azimuthal field.

The experimentally observed lifetime of the closed configuration is about 7 μsec and is evidently limited by the discharge period (compression phase lasts for $T/4 = 7.5$ μsec). The plasma confinement time in systems with an axial current-carrying rod[2-4] is 20-30 μsec and is limited either by the instability caused by plasma rotation or by the decrease in stability margin during the discharge. In our case the maximum possible confinement time is limited by the diffusion time of the magnetic field, which for typical discharge parameters[9] ($T_e \approx 1$ keV) is of the order of several hundredths of a microsecond.

Increasing the discharge period without considerable changes in the other parameters probably can considerably increase the lifetime of a given magnetic configuration. This makes it possible to study sufficiently rapid processes, such as plasma heating, development of instabilities; etc. in closed magnetic systems.

During the discharge the major and minor radii of the toroidal surfaces are compressed. The most rapid changes occur in the first 1-1.5 μsec; afterwards, the dimensions remain essentially constant. The existence inside the plasma ring of a reverse magnetic flux makes it possible for a certain equilibrium configuration of the ring to be attained.

With a sufficiently rapid decrease in cross-sectional area of the plasma ring the magnetic flux through the cross section is maintained, which leads to a deviation in distribution of the toroidal field B_φ from the $B_\varphi \sim 1/r$ law (Fig. 2). Poloidal surface currents with density of order 1 kA/cm² are observed.

The existence of a difference between the toroidal magnetic field inside the plasma and outside it affects the equilibrium and stability of the plasma,[10] since it changes the balance of pressure, and creates additional shear on the surface. Furthermore, if the surface currents are not parallel to **B**, then the ponderomotive force $F_\varphi = (j_z B_r - j_r B_z)(1/c)$ causes the plasma to rotate, which can lead to instabilities.

Based on the method of production (plasma current) the magnetic configuration being investigated is similar to Tokamaks, but based on its parameters (shear, magnetic well, shape of cross section) it is close to Spherators.

CONCLUSIONS

1. In a θ-pinch system with an applied azimuthal magnetic field there exist Tokamak-type closed magnetic configurations.

2. The cross sections of the magnetic surfaces are extended along the axis of the system. The characteristic dimensions of the cross sections are of the order of the major radius of the surfaces.

3. The system has mean minimum B of the order of several tens of percent and shear $S \approx 0.4$.

4. It is possible to use the θ-pinch system with an applied azimuthal field to study rapid processes (instability, turbulence) for toroidal plasma confinement.

The authors thank V. P. Sebko and V. I. Tyup for useful discussion.

Damping of ion-acoustic waves in a bounded plasma

A. N. Kondratenko and V. M. Kuklin

A. M. Gor'kii Khar'kov State University

(Submitted April 6, 1973; resubmitted September 3, 1973)
Zh. Tekh. Fiz., 44, 519-524 (March 1974)

The propagation of surface and volume ion-acoustic waves along the axis of a cylindrical plasma waveguide in a constant magnetic field is considered. The problem is solved in the linear hydrodynamic approximation. The dispersion equations are investigated; phase and group velocities and damping factors for the waves are determined. The damping factors contain a term collisional–dissipative term as a resonance associated with the presence of an inhomogeneous transition layer. It is shown that the properties of volume ion-acoustic waves in an unbounded plasma can be different from those in a waveguide of small radius.

DISPERSION EQUATION

Surface ion-acoustic waves in a strongly nonisothermal ($T_e \gg T_i$) plasma layer with a sharp boundary have been investigated.[1,2] In experiments, however, one often has to deal with cylindrical plasma waveguides rather than plasma layers. In addition, a sharp boundary is usually not realized with a gaseous plasma and there is a finite transition layer of inhomogeneous plasma where one should expect absorption of wave energy because of resonance effects.[3-6] In this paper we study the propagation of low-frequency waves ($\omega \ll \Omega_i$, where Ω_i is the ion plasma frequency) in a cylindrical waveguide filled with an inhomogeneous highly nonisothermal plasma.

The plasma is in a fixed magnetic field H_0 oriented along the z axis of the plasma column. We consider symmetric waves for which $\partial/(\partial\varphi) = 0$. We choose the dependence of perturbed quantities on the coordinate z and time in the form $\exp i(k_3 z - \omega t)$. The unperturbed density of singly charged ions and of electrons is assumed to be constant and equal to n_0 in the radial interval $0 \le r \le R_1$, and to decrease monotonically to zero for $R_n < r \le R_2$.

Since the phase velocity of these low-frequency waves is much smaller than the thermal velocity of plasma electrons, v_T, the magnetic field of the wave can be neglected. From the linearized Maxwell equations and the hydrodynamic equations we obtain a system of two equations for the electric field of the ion-acoustic wave:

$$\frac{dE_z}{dr} = ik_3 E_r, \tag{1}$$

$$E_z = \frac{-i}{k_3 g(r) r} \frac{d}{dr}(r\varepsilon_1 E_r), \tag{2}$$

where

$$g(r) = -\varepsilon_3 - \frac{\Omega_e^2(r)}{k_3^2 v_T^2}, \quad \varepsilon_1 = 1 - \frac{\Omega_i^2(r)}{\omega(\omega + i\nu) - \omega_i^2}, \quad \varepsilon_3 = 1 - \frac{\Omega_i^2(r)}{\omega(\omega + i\nu)},$$

$$\Omega_{i,e}^2 = \frac{4\pi e^2 n}{m_{i,e}}, \quad \omega_i = \frac{eH_0}{m_i c},$$

ν is the effective ion collision frequency (it is assumed $\nu \ll \omega$) and $m_{i,e}$ is respectively the ion or electron mass.

Eliminating E_z from Eqs. (1) and (2), we obtain an equation for the determination of the component E_r:

$$\varepsilon_1 \frac{d}{dr}\left[\frac{1}{g(r) r} \frac{d}{dr}(rF)\right] + k_3^2 F = 0, \tag{3}$$

where $F = \varepsilon_1 E_r$.

The system (1)-(3) holds for $c \to \infty$, or, more rigorously, $c \gg \omega R_1$, ω/k_3, where c is the velocity of light.

Solving (2) and (3) in the homogeneous plasma region $r < R_1$, we obtain the following expression for the components of the field:

$$E_r = C_0 I_1(\varkappa r), \tag{4}$$

$$E_z = iC_0 \frac{k_3}{\varkappa} I_0(\varkappa r), \tag{5}$$

where

$$\varkappa^2 = \frac{\varepsilon_{30}}{\varepsilon_{10}}\left(k_3^2 + \frac{\Omega_{e0}^2}{v_T^2 \varepsilon_{30}}\right), \tag{6}$$

$I_n(x)$ is the Bessel function of imaginary argument; ε_{10}, ε_{30}, and Ω_{e0} are the values of the corresponding quantities in the homogeneous plasma region; C_0 is a constant.

Setting the wave amplitude at the vacuum boundary equal to unity, we obtain for the region $r > R_2$

$$E_r = K_1(k_3 r), \tag{7}$$

$$E_z = -iK_0(k_3 r), \tag{8}$$

where $K_n(x)$ is the MacDonald function.

In the transition region $R_1 < r < R_2$ (assuming it to be small,

$$|\varkappa(R_2 - R_1)| \ll 1, \quad k_3(R_2 - R_1) \ll 1, \tag{9}$$

the solution of the system (2), (3) can be represented by a series in powers of the small parameter (9). Limiting the series to the first two terms of the expansion, we obtain

$$F(r) = \frac{A}{r}\int_{R_1}^{r} g(r')r'dr'\left[1 - k_3^2\int_{R_1}^{r'} \frac{dr''}{\varepsilon_1(r'')r''}\int_{R_1}^{r''} g(\rho)\rho d\rho - \ldots\right]$$
$$+ \frac{B}{r}\left[1 - k_3^2\int_{R_1}^{r} g(r')r'dr'\int_{R_1}^{r'} \frac{dr''}{\varepsilon_1(r'')r''} - \ldots\right], \tag{10}$$

$$iE_z(r) = \frac{A}{k_3}\left[1 - k_3^2\int_{R_1}^{r} \frac{dr'}{\varepsilon(r')r'}\int_{R_1}^{r'} g(r'')r''dr'' - \ldots\right]$$
$$- Bk_3\int_{R_1}^{r} \frac{dr'}{\varepsilon_1(r')r'} - \ldots. \tag{11}$$

The constants A and B are determined from the continuity of the fields at the interface with the homogeneous plasma:

$$A = -\frac{k_3^2}{\varkappa} C_0 I_0(\varkappa R_1), \tag{12}$$

$$B = R_1 \varepsilon_{10} C_0 I_1(\varkappa R_1). \tag{13}$$

Continuity of the fields at the vacuum boundaries make it possible to obtain the dispersion equation

$$A\left\{-\int_{R_1}^{R_2} g(r)\, r\, dr \left[1 - k_3^2 \int_{R_1}^{r} \frac{dr'}{\varepsilon_1(r')\, r'} \int_{R_1}^{r'} g(r'')\, r'' dr''\right] + \frac{R_2 K_1(k_3 R_2)}{k_3 K_0(k_3 R_2)}\left[1 - k_3^2 \int_{R_1}^{R_2} \frac{dr}{\varepsilon_1(r)\, r} \int_{R_1}^{r} g(r')\, r' dr'\right]\right\}$$
$$- B\left[1 - k_3^2 \int_{R_1}^{R_2} g(r)\, r\, dr \int_{R_1}^{r} \frac{dr'}{\varepsilon_1(r')\, r'} + \frac{k_3 R_2 K_1(k_3 R_2)}{K_0(k_3 R_2)} \int_{R_1}^{R_2} \frac{dr}{\varepsilon_1(r)\, r}\right] = 0. \tag{14}$$

Neglecting small terms proportional to (9) and considering only the contribution of the resonance portion of the last integral in Eq. (14), we write it in the form

$$f(k_3 R_2) + \varkappa R_1 \varepsilon_{10} \frac{I_1(\varkappa R_1)}{I_0(\varkappa R_1)} = -\frac{\pi i r^*}{R_1} f^2(k_3 R_2), \tag{15}$$

where

$$r^* = -\frac{R_1}{r} \left.\frac{\omega^2 - \omega_i^2}{\frac{d\Omega_i^2(r)}{dr}}\right|_{r=R_0}, \quad f(z) = z\frac{K_1(z)}{K_0(z)},$$

and R_0 is determined from the condition Re $\varepsilon_1(R_0) = 0$.

SURFACE WAVES

Neglecting dissipative effects (particle collisions and absorption of wave energy in the resonance layer), the dispersion equation (15), which describes the propagation of surface waves ($\varkappa^2 > 0$) in a plasma waveguide with sharp boundaries ($R_1 = R_2 = R$), takes the form

$$-\varepsilon_{10} \frac{\varkappa}{k_3} \frac{I_1(\varkappa R)}{I_0(\varkappa R)} = \frac{K_1(k_3 R)}{K_0(k_3 R)}. \tag{16}$$

Letting the phase velocity of the wave go to zero ($k_3 \to \infty$), we find an upper bound for the frequency:

$$\omega_{\text{ub}} = \sqrt{\frac{\Omega_{i0}^2 + \omega_i^2}{2}}. \tag{17}$$

In the limit of large waveguide radius, the wave is a surface wave and it is easily shown that the frequency falls in the range $\omega_i < \omega < \omega_{\text{ub}}$.

We consider a number of special cases.

a) In a semiinfinite plasma, the dispersion equation (16) takes the form

$$k_3^2 = \frac{\Omega_{i0}^2 \varepsilon_{10}}{v_s^2 (1 - \varepsilon_{10}\varepsilon_{30})}, \tag{18}$$

where $v_s = \sqrt{T_e/m_i}$ is the ion-acoustic velocity.

If the frequency of the wave is much smaller than the ion plasma frequency, $\omega \ll \Omega_{i0}$, the dependence of ω on k_3 is the same as for acoustic waves in a unbounded plasma:

$$\omega = k_3 v_s. \tag{19}$$

In addition, $\varkappa \ll k_3$, and the wave penetrates far into the plasma. When the frequency approaches the limiting values, k_3 and $\varkappa$ increase rapidly, the wave is confined to the boundary of the plasma, and the phase velocity goes to zero.

Letting $k_3 \to k_3' = k_3 + i\delta$, $\delta \ll k_3$, from Eq. (15) we obtain the damping factor for a wave in a semiinfinite medium:

$$\frac{\delta}{k_3} = \frac{\nu\omega(1 - \varepsilon_{10})}{(\omega^2 - \omega_i^2)\, \varepsilon_{10}(1 - \varepsilon_{10}\varepsilon_{30})} + \pi \frac{r^*}{r_d^2} \sqrt{\frac{\varepsilon_{10}}{(1 - \varepsilon_{10}\varepsilon_{30})^3}}, \tag{20}$$

where $r_d = \Omega_{e0}/v_T$.

The second term in Eq. (20) is responsible for resonance damping of the wave in the transition region of the plane. If the frequency ω approaches the frequency bound ω_{ub}, Eq. (20) is inapplicable, the damping factor rises rapidly, and the wave is highly damped.

The phase velocity and group velocity for a weakly damped wave are

$$v_{\text{ph}} = v_s \frac{\omega}{\Omega_{i0}} \sqrt{\frac{1 - \varepsilon_{10}\varepsilon_{30}}{\varepsilon_{10}}}, \tag{21}$$

$$v_{\text{gr}} = 2\frac{v_s \sqrt{\varepsilon_{10}(1 - \varepsilon_{10}\varepsilon_{30})^3}}{\Omega_{i0}\left(\frac{\partial\varepsilon_{10}}{\partial\omega} + \varepsilon_{10}^2 \frac{\partial\varepsilon_{30}}{\partial\omega}\right)}. \tag{22}$$

b) If the depth of penetration into the plasma is much greater than the waveguide radius,

$$\varkappa R \ll 1, \tag{23}$$

the dispersion equation (16) becomes

$$-\varepsilon_{30}\varkappa^2 R^2 = 2f(k_3 R). \tag{24}$$

Since $f(x) \gtrsim 1$ for all $x = k_3 R$ with the exception of a small neighborhood near $x = 0$, where $f(x)$ decreases as $1/\ln x$, $|\varepsilon_{30}| \gg 1$ is a condition for expanding Eq. (24).

Solving Eq. (24) with respect to frequency, we find

$$\omega = \frac{\Omega_{i0} k_3 R r_d}{\sqrt{R^2 + 2r_d^2 f(k_3 R)}}. \tag{25}$$

It is easy to see that $k_3 r_d \ll 1$ follows from the condition $\omega \ll \Omega_{i0}$. Thus $f r_d^2 \ll R^2$ and the dispersion equation for a narrow plasma waveguide is the same as that for acoustic waves in an unbounded plasma [Eq. (19)].

The damping factor is given by

$$\frac{\delta}{k_3} = \frac{\nu}{2\omega} + \frac{\pi r^* r_d^2 f^2(k_3 R)}{R^3}. \tag{26}$$

It then follows that damping of a wave in a narrow cylindrical waveguide is always small if $\nu \ll \omega$, $r_d \ll R$.

The phase and group velocities of the wave differ very little from the ion-acoustic velocity v_s in a unbounded plasma.

c) These results obtained can be generalized to the case of a narrow inhomogeneous cylinder in which the plasma density varies monotonically along the radius. For this case (23) is written

$$\left| k_3^2 \int_0^R \frac{dr}{\varepsilon_1(r) r} \int_0^R g(r') r' dr' \right|^{1/2} \ll 1. \tag{27}$$

The dispersion equation (15) is inapplicable and one should use Eq. (14), setting $R_1 = 0$, $R_2 = R$, and $B = 0$. As in the preceding case, the relationship $\omega(k_3)$ has the form (19). The damping factor is determined from Eq. (26), where all quantities are replaced by their average values

$$\bar{y} = \frac{2}{R^2} \int_0^R y(r) r dr. \tag{28}$$

As before, the damping of the wave is small, and the phase and group velocities are of the same order as v_s.

In the last two cases the constant magnetic field $H_0 < (\omega c m_i / e)$ has no effect on the propagation of the ion-acoustic waves. When the inequality is reversed, surface low-frequency waves are not excited in a plasma.

VOLUME WAVES

If $\varkappa^2 < 0$, as in Eq. (6), the fields in the plasma are expressed by oscillating Bessel functions of the first kind and represent volume waves. For large waveguide radii, the volume low-frequency waves do not differ from ordinary ion-acoustic waves in an unbounded plasma and their properties do not depend on boundary effects. For small radii, however, the properties of ion-acoustic waves in bounded and unbounded plasma can be quite different.

The dispersion equation for ion-acoustic waves in a plasma waveguide, including resonance absorption effects, has the following form ($R_2 - R_1 \ll R_1 = R$):

$$-\varepsilon_{10} q R \frac{J_1(qR)}{J_0(qR)} + f(k_3 R) = -\pi i \frac{r^*}{R} f^2(k_3 R), \tag{29}$$

where

$$q = i\varkappa = \left[-\frac{\varepsilon_{30}}{\varepsilon_{10}} \left(k_3^2 - \frac{\Omega_{i0}^2}{v_T^2 \varepsilon_{30}} \right) \right]^{1/2}.$$

The left side of Eq. (29) defines $k_3(\omega)$. It can be defined with satisfactory accuracy in the following manner. Within the limits of a monotonic variation of $k_3(\omega)$, we let k_3 go to zero. Then $f \to 0$ and $qR \approx \lambda_{p1}$, where λ_{p1} is a root of the first-order Bessel function. If $k_3 \to \infty$, then $f \to \infty$ and $qR \approx \lambda_{p0}$, where λ_{p0} is a root of the zero-order Bessel function. It is reasonable to assume that

$$q \approx \frac{\lambda_p}{R}, \tag{30}$$

where λ_p falls between λ_{p0} and λ_{p1}. We then determine $k_3(\omega)$ from

$$k_3^2 = -\frac{1}{\varepsilon_{30}} \left(\frac{1}{r_d^2} + \varepsilon_{10} \frac{\lambda_p^2}{R^2} \right). \tag{31}$$

Using Eq. (31) we determine the frequency region in which volume ion-acoustic waves can be excited. In the case of a strong magnetic field $\omega_i > \Omega_{i0}$, two frequency ranges are possible: $0 < \omega < \Omega_{i0}$ and $\omega_i < \omega < \omega_1$, where

$$\omega_1 = \left[\omega_i^2 + \Omega_{i0}^2 \left(1 + \frac{R^2}{r_d^2 \lambda_p^2} \right)^{-1} \right]^{1/2}. \tag{32}$$

In the second range, the signs of the phase and group velocities are different. If $\omega_i < \Omega_{i0}$, the frequency region is also represented by two ranges: $0 < \omega < \omega_i$ and $\omega \in (\omega_1, \Omega_{i0})$. In the second range for this case, anomalous dispersion is also observed when $\omega_1 > \Omega_{i0}$.

For large waveguide radii the last term in Eq. (31) is small and $k_3(\omega)$ is similar to the dispersion law in an unbounded plasma. In some cases, however, both terms on the right in Eq. (31) can be of the same order of magnitude.

Assuming that the damping is small, we obtain the damping factor of the wave from Eq. (29):

$$\frac{\delta}{k_3} \approx \frac{\nu}{4} \left[\frac{\lambda_p^2 r_d^2}{R^2 + \varepsilon_{10} \lambda_p^2 r_d^2} \frac{d\varepsilon_{10}}{d\omega} - \frac{1}{\varepsilon_{30}} \frac{d\varepsilon_{30}}{d\omega} \right] - \frac{\pi r^* J_0^2(\varkappa R) K_1^2(k_3 R)}{R \varepsilon_{30} K_0^2(k_3 R)}. \tag{33}$$

As in the case of surface waves, the second term in Eq. (33) represents resonance absorption of wave energy in the homogeneous plasma layer. As is clear from the expression given above, resonance damping is inversely proportional to waveguide radius and vanishes in a semi-infinite plasma. For small waveguide radii one expects a strong increase in resonance damping. We also give the group velocity of the wave:

$$v_{gr} = \frac{-2}{k_3} \left[\frac{1}{\varepsilon_{30}} \frac{d\varepsilon_{30}}{d\omega} + \frac{\lambda_p^2}{\varepsilon_{30} R^2 k_3^2} \frac{d\varepsilon_{10}}{d\omega} \right]^{-1}. \tag{34}$$

For a fixed wave vector k_3, the time decrement $\mathrm{Im}\,\omega = \gamma$ is easily determined for the case of weak damping ($\gamma \ll \omega$) from the following expression:

$$\gamma = v_{gr} \delta. \tag{35}$$

Forces in a Hall plasma accelerator

O. N. Mironov

(Submitted July 9, 1973)
Zh. Tekh. Fiz., 44, 525-535 (March 1974)

The forces in a stationary Hall plasma accelerator are calculated. Analytic expressions are obtained for the average flow parameters at the accelerator exit and the forces as functions of dimensionless parameters characterizing the flow and plasma acceleration in the accelerator channel. The results are of interest in the evaluation of accelerator characteristics and in the analysis of plasma flow in the channel.

Plasma acceleration under stationary conditions can be accomplished in various ways. For example, if an external magnetic field coaxial with the electrodes is superimposed on an electric discharge in a plasma of low or medium density (10^{12}–10^{15} cm^{-3}) which is heated between coaxial electrodes, the rate of plasma emission and the accelerator efficiency can be increased significantly.[1-3] In the literature, such accelerators have been called magnetoplasmodynamic accelerators[2,3] or Hall accelerators.[1,4] In these accelerators, in the MHD approximation plasma acceleration occurs mainly through the effect of the electromagnetic Ampere force $j_\theta = b_r$. The appearance of an Ampere force is associated with the creation of a Hall current with density j_θ due to closed electron drift in the crossed electromagnetic fields. In contrast to the arrangement discussed in ref. 5, plasma flow along the channel in this acceleration scheme is a three-component flow. Therefore, the analysis and calculation of the forces which act in the various directions and which determine flow structure are of particular interest. In addition, such an analysis is important from the viewpoint of evaluating the capabilities of Hall accelerators. The present paper is concerned with these equations.

1. FORMULATION OF THE PROBLEM

We consider steady-state flow of a neutral plasma in an axisymmetric channel, a diagram of which is shown in Fig. 1. Let the working material be fed into the accelerator channel through the central electrode, which is the cathode. We assume this material is ionized near the cathode so that plasma in the channel is propagated from the cathode in the form of a jet in which the degree of ionization is constant. We choose a general system for electric current flow in the channel and calculate the forces under the following assumptions.

1. The plasma is nonviscous and thermally nonconducting.

2. The working material is singly ionized.

3. The plasma is ionized to a high degree so that we need not consider slippage of ions relative to neutrals.

4. The plasma approximation is valid, i.e., the ion and electron densities are equal in all flow regions.

The time-averaged plasma behavior is treated, i.e., time variations of the parameters in the equations are neglected.

6. The plasma flow is axisymmetric.

In accelerators with this arrangement, the Hall parameter for the electrons is usually greater than or equal to unity, and the Hall parameter for ions is much less than unity. To achieve this condition a magnetic field is created which satisfies the condition

$$R_{iL} > R_s \gg R_{eL},$$

where R_{iL} and R_{eL} are the Larmor radii for ions and electrons respectively and R_s is the characteristic transverse dimension of the channel. Under these assumptions we can write the following conservation laws for steady-state plasma flow:[6]

$$\left.\begin{aligned} &\operatorname{div}\rho\mathbf{v} = 0, \quad \rho(\mathbf{v}\nabla)\mathbf{v} = -\nabla p + \mathbf{j}\times\mathbf{B}, \\ &\rho(\mathbf{v}\nabla)\left(h + \frac{\mathbf{v}^2}{2}\right) = \mathbf{j}\cdot\mathbf{E}, \quad \operatorname{div}\mathbf{j} = 0. \end{aligned}\right\} \tag{1.1}$$

In order to obtain a closed system of equations we add to Eq. (1.1) a generalized Ohm's law of the form

$$\mathbf{j} = \sigma\left(\mathbf{E} + \mathbf{v}\times\mathbf{B} - \frac{\mathbf{j}\times\mathbf{B}}{n_e e} + \frac{\nabla p_e}{n_e e}\right), \tag{1.2}$$

where ion slip is neglected, and Maxwell's equations for the electromagnetic field:

$$\operatorname{curl}\mathbf{B} = \mu\mathbf{j}, \ \operatorname{div}\mathbf{B} = 0, \operatorname{curl}\mathbf{E} = 0. \tag{1.3}$$

The connection between the thermodynamic variables h (enthalpy), p, and ρ and the dependence of the transfer coefficients on these same variables is assumed to be known. Conventional notation is used in Eqs. (1.1), (1.2), and (1.3).

We introduce a cylindrical coordinate system (r, θ, x) with origin coinciding with the center of the end surface of the cathode. Let the initial distributions of all quantities be given and the basic variables have the following components:

$$\mathbf{v}\{v,\ w,\ u\},\ \ \mathbf{j}\{-j_r,\ -j_\theta,\ -j_x\},\ \mathbf{B}\{b_r,\ -b_\theta,\ b_x\}.$$

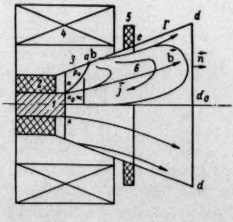

Fig. 1. Diagram of the accelerator. 1) Cathode; 2, 5) insulators; 3) anode; 4) solenoid; 6) region of current flow and plasma acceleration.

The equation of motion in component form for a steady-state axisymmetric flow can be written

$$\left.\begin{aligned} \rho\mathbf{v}\cdot\nabla(vr)-\rho(v^2+w^2) &= -r\frac{\partial p}{\partial r}-j_\theta b_x-j_x b_\theta, \\ \rho\mathbf{v}\cdot\nabla(wr) &= j_r b_x - j_x b_r, \\ \rho\mathbf{v}\cdot\nabla(u) &= -\frac{\partial p}{\partial x}+j_r b_\theta + j_\theta b_r. \end{aligned}\right\} \quad (1.4)$$

We consider the surface Γ (Fig. 1), which encompases the entire volume where electromagnetic forces act on the plasma and which is represented in a meridian plane passing through the accelerator axis by the contour $k_0 k a b e d d_0 k_0$. The following boundary conditions and initial conditions must be satisfied at the boundaries of this contour:

$$\left.\begin{aligned} &\mathbf{j}\cdot\mathbf{n}=0 \text{ on } ka,\ bed,\ dd_0. \\ &\mathbf{v}\cdot\mathbf{n}=0 \text{ on } ka,\ abed. \\ &p=p_{\mathrm{H}} \text{ on } edde. \\ &-\int_{A_{kk}}\rho\mathbf{v}\cdot\mathbf{n}\,dA=\int_{A_{dd}}\rho\mathbf{v}\cdot\mathbf{n}\,dA=G, \\ &\int_{A_{kk}}\mathbf{j}\cdot\mathbf{n}\,dA=-\int_{S_{ab}}\mathbf{j}\cdot\mathbf{n}\,dS=J_{\mathrm{d}}. \end{aligned}\right\} \quad (1.5)$$

Here, **n** is the outward normal from the surface Γ, A is the area of the cross section of the channel, S is the area of the surface Γ corresponding to the contour segment $k_0 k a b d d_0 k_0$, G is the flow rate of the working material, and J_d is the total discharge current.

Equation (1.4) and the boundary conditions (1.5) make it possible to calculate the change in plasma momentum and angular momentum due to the electromagnetic forces. We integrate the x component of the equation of motion over the volume in which the discharge current interacts with the external magnetic field with dV = dAdx, $dA = \pi dr^2$. Using the vector identity $\rho\mathbf{v}\cdot\nabla(u) = \operatorname{div}\rho u\mathbf{v} - u\operatorname{div}\rho\mathbf{v}$, the continuity equation $\operatorname{div}\rho\mathbf{v} = 0$, and Gauss's theorem, we obtain

$$\oiint_{\Gamma}\rho u\mathbf{v}\cdot\mathbf{n}\,dA=-\oiint_{\Gamma}p\mathbf{n}\cdot\mathbf{e}_x\,dA+\int_0^x\int_A(j_r b_\theta+j_\theta b_r)\,dA\,dx. \quad (1.6)$$

The plasma momentum in the section dd under boundary conditions (1.5) is according to Eq. (1.6) determined by the expression

$$\int_{A_{dd}}\rho u^2 dA=\int_{A_{kk}}(\rho u^2+p)\,dA-\int_{A_{ee}}p_{\mathrm{H}}\,dA +\int_0^{L_0}p_R\left(\frac{dA}{dx}\right)dx+\int_V(j_r b_\theta+j_\theta b_r)\,dV, \quad (1.7)$$

where L_0 is the accelerator length from cathode to exit section and p_R is the pressure at the channel boundary. The first term on the right in Eq. (1.7) corresponds to the initial plasma momentum and pressure in the initial section, the second term to the counterpressure of the surrounding gas, the third term of the plasma pressure on the channel wall (outside the contour boundary k*a* the pressure is assumed constant), and the last term to the electromagnetic forces applied to the solenoid ($\int_V j_\theta b_r dV$) and to the current-carrying circuit ($\int_V j_r b_\theta dV$). Ordinarily the initial plasma momentum and the counterpressure of the surrounding gas can be neglected. Actually, the ratio of initial momentum to final momentum in order of magnitude for the case of effective plasma acceleration is

$$\frac{\int_{A_{kk}}\rho u^2 dA}{\int_{A_{dd}}\rho u^2 dA}\sim\frac{u(x=0)}{u(x=L_d)}\simeq 0.05-0.01.$$

Here, L_d is the distance along the x axis from the cathode to the section in which the interaction of discharge current and plasma flow with the external magnetic field can be assumed complete. The force resulting from counterpressure of the surrounding gas can be neglected if the pressure p_H satisfies the condition

$$\frac{\int_{A_{ee}}p_{\mathrm{H}}\,dA}{\int_{A_{dd}}\rho u^2 dA}\sim\frac{p_{\mathrm{H}}A_{ee}}{Gu(x=L_d)}\ll 1.$$

This condition is satisfied in most cases.

The pressure in the initial section can be eliminated from Eq. (1.7) if the equation for plasma equilibrium in the radial direction is used. We assume that v = w = 0 at the cathode. Then if the plasma flow in the initial section is irrotational, i.e., $\partial v/\partial x = \partial u/\partial r$, and the profile of the axial flow velocity is uniform in the radial direction, the inertial terms are essentially zero. Integrating the remaining terms in the first equation of the system (1.4) over the area of the transverse section of the channel ($dA = \pi dr^2$), we obtain

$$\int_{A_{kk}}p\,dA=p_* A_{kk}-\frac{1}{2}\int_{A_{kk}}(j_\theta b_x+j_x b_\theta)\,r\,dA. \quad (1.8)$$

In Eq. (1.8), p_* is the pressure in the channel outside the boundaries of the current region (Fig. 1). When the pressure in the section dd is approximately equal to p_H the reactive force acting on the accelerator will be numerically equal to the plasma momentum in the section dd. In view of these estimates and Eq. (1.8) we can write

$$F=\int_{A_{dd}}\rho u^2 dA=F_B+F_c+F_a, \quad (1.9)$$

$$F_B=\int_V j_\theta b_r\,dA\,dx-\frac{1}{2}\int_{A_{kk}}j_\theta b_x r\,dA, \quad (1.10)$$

$$F_c=\int_V j_r b_\theta\,dA\,dx-\frac{1}{2}\int_{A_{kk}}j_x b_\theta r\,dA, \quad (1.11)$$

$$F_a=p_* A_{kk}+\int_0^L p_R\frac{dA}{dx}\,dx. \quad (1.12)$$

Here, F_B is the force which arises because of interaction of the discharge current with the external magnetic field and which is applied to the solenoid and to the accelerator cathode; F_c is the force which arises because of the interaction between the discharge current and the self-magnetic field and which is applied to the current-carrying circuit and to the cathode; F_a is the aerodynamic component of the reaction force resulting from plasma pressure on the channel walls. It is clear that the aerodynamic component of the reaction force can be neglected when there are strong electromagnetic fields. An expression for the angular momentum can be obtained if the second equation in the system (1.4) is integrated over the interaction volume for the electromagnetic forces. Actually, using the vector equality $\rho \mathbf{v} \cdot \nabla(wr) = \operatorname{div}(\rho \mathbf{v} \cdot wr) - wr \operatorname{div} \rho \mathbf{v}$, the relation $\operatorname{div} \rho \mathbf{v} = 0$, the boundary condition $\mathbf{v} \cdot \mathbf{n} = 0$ on the lateral surface of the region of integration, and Gauss's theorem, in a manner similar to that used above, we obtain

$$\int_{A_{dd}} \rho u w r\,dA = \int_{A_{kk}} \rho u w r\,dA + \int_A \int_0^x (j_r b_x - j_x b_r)\,dA\,dx. \qquad (1.13)$$

The integral relation (1.13) determines the angular momentum of the plasma in the section dd; for a given radial dependence of w it can be used to calculate the angular velocity and moment of inertia of the plasma in that section.

Experiments[7] indicate that the plasma rotates as a unit, i.e., $w = \omega r$. Substituting $w = \omega r$ in Eq. (1.13) and converting to averaged parameters

$$\int_A \rho u \omega r\,dA \simeq \rho u \omega \int_A r^2\,dA$$

for $\omega(x = 0) = 0$, $G = \rho u \pi R^2$ we have

$$\omega_d = \frac{2\int_A \int_0^x (j_r b_x - j_x b_r)\,dA\,dx}{G R_d^2}. \qquad (1.14)$$

In Eq. (1.14), R_d and ω_d are the radius of the jet and the angular velocity of the plasma in the section dd, G is the flow rate of the working material through a cross section of the channel. The quantity $GR_d^2/2$ is the moment of inertia of the plasma.

When $F_a \ll F_B$, by converting to averaged flow parameters, $\int_{A_{dd}} \rho u^2\,dA = uG$, we have the following relation for the average plasma velocity in section dd:

$$u_d = \frac{F_a + F_c}{G}. \qquad (1.15)$$

2. CALCULATION OF ELECTROMAGNETIC FORCES

We now calculate the integrals for the electromagnetic forces. The force F_c has been calculated previously[8,9] for an axisymmetric discharge assuming the absence of bunching. It is proportional to the square of the total discharge current. In calculating the integrals in Eqs. (1.10) and (1.14) we note that Ohm's law neglecting ion slip can be written as

$$\mathbf{j} = \frac{\sigma(\alpha)}{\alpha n_0 e}\left(n_e e\mathbf{E} + \frac{e}{m_i}\alpha \mathbf{g} \times \mathbf{B} - \mathbf{j} \times \mathbf{B} + \nabla p_e\right). \qquad (2.1)$$

Here, $\mathbf{g} = \rho \mathbf{v}$ is the mass flow vector, α is the degree of ionization, m_i is the mass, and n_0 is the total number of particles per unit volume. We now vectorially multiply the current density determined from Ohm's law in the form (2.1) by the field induction $\mathbf{b}$ and write the resultant expression in component form. For the axisymmetric case ($\partial/\partial\theta = 0$), using the vector relation $(\mathbf{j} \times \mathbf{B}) \times \mathbf{b} = (\mathbf{j} \cdot \mathbf{b}) \cdot \mathbf{B} - (\mathbf{B} \cdot \mathbf{b}) \cdot \mathbf{j}$, and for $\mathbf{b}_i \perp \mathbf{b}$, $\mathbf{j}\{-j_r, -j_\theta, -j_x\}$, $\mathbf{g}\{g_r, g_\theta, g_x\}$, $\mathbf{b}\{b_r, 0, b_x\}$, we obtain

$$j_\theta b_r = \beta_r\left[\frac{e\alpha}{m_i}(g_r b_x - g_x b_r) + (j_r b_x - j_x b_r)\right], \qquad (2.2)$$

$$j_\theta b_x = -\beta_x\left[\frac{e\alpha}{m_i}(g_r b_x - g_x b_r) + (j_r b_x - j_x b_r)\right], \qquad (2.3)$$

$$(\mathbf{j} \times \mathbf{b})_\theta = j_r b_x - j_x b_r. \qquad (2.4)$$

Here, $\beta_x = \sigma(\alpha) b_x/(\alpha n_0 e)$ is the Hall parameter calculated for the axial component of the field; $\beta_r = \sigma(\alpha) b_r/(\alpha n_0 e)$ is the Hall parameter calculated for the radial component of the field. The field intensity $\mathbf{E}$ does not appear in Eqs. (2.2) and (2.3) because $(\mathbf{E} \times \mathbf{b})_r = (\mathbf{E} \times \mathbf{b})_x = 0$. Using the equations

$$\begin{gathered}\frac{\partial \Psi}{\partial r} = g_x r, \quad \frac{\partial \Psi}{\partial x} = -g_r r, \quad \frac{\partial J}{\partial r} = j_x r, \\ \frac{\partial J}{\partial x} = -r j_r, \quad \frac{\partial \Phi}{\partial r} = r b_x, \quad \frac{\partial \Phi}{\partial x} = -r b_r,\end{gathered} \qquad (2.5)$$

we introduce functions for the mass flow, electric current, and magnetic field, where

$$\Psi = \int_0^r g_x r\,dr, \quad J = \int_0^r j_x r\,dr, \quad \Phi = \int_0^r b_x r\,dr. \qquad (2.6)$$

In this case, the equations for the conservation of mass and charge and for continuity of magnetic lines of force ($\operatorname{div} \mathbf{b} = 0$) are satisfied automatically. We replace the quantities g_x, g_r, j_x, j_r, b_x, b_r in Eqs. (2.2), (2.3) and (2.4) by the corresponding derivatives of current functions in Eqs. (2.5). Because of the relation

$$\frac{\partial}{\partial x}\left(f \frac{\partial \varphi}{\partial z}\right) = f \frac{\partial^2 \varphi}{\partial x \partial z} + \frac{\partial f}{\partial x}\frac{\partial \varphi}{\partial z}$$

after simple transformations we have

$$\left.\begin{gathered} j_\theta b_r = -\beta_x(\alpha)\frac{b_r}{b_x}\frac{1}{r^2}\left\{\frac{e\alpha}{m_i}\left[\frac{\partial}{\partial x}\left(\Psi \frac{\partial \Phi}{\partial r}\right) - \frac{\partial}{\partial r}\left(\Psi \frac{\partial \Phi}{\partial x}\right)\right]\right. \\ \left. + \frac{\partial}{\partial x}\left(J \frac{\partial \Phi}{\partial r}\right) - \frac{\partial}{\partial r}\left(J \frac{\partial \Phi}{\partial x}\right)\right\}, \\ j_\theta b_x = -\frac{b_x}{b_r} j_\theta b_r, \\ (\mathbf{j} \times \mathbf{b})_\theta = -\frac{1}{r^2}\left[\frac{\partial}{\partial x}\left(J \frac{\partial \Phi}{\partial r}\right) - \frac{\partial}{\partial r}\left(J \frac{\partial \Phi}{\partial x}\right)\right]. \end{gathered}\right\} \qquad (2.7)$$

The equations (2.7) make it possible to calculate the integrals $\int_V j_\theta b_x r\,dA\,dx$ and $\int_V (\mathbf{j} \times \mathbf{b})_\theta r\,dA\,dx$. Indeed, if we take the Hall parameter outside the integral sign in the integral $\int_V j_\theta b_x r\,dA\,dx$ using the theorem of the mean, by the use of Green's equation (plane analogy of Gauss's theorem) we have

$$\int_V j_\theta b_x r\,dA\,dx = -2\pi \langle \beta_x \rangle \oint \left(\frac{e\alpha}{m_i}\Psi + J\right) d\Phi, \qquad (2.8)$$

$$\int_V (\mathbf{j} \times \mathbf{b})_\theta r\,dA\,dx = 2\pi \oint J\,d\Phi. \qquad (2.9)$$

The integration is carried out along the closed contour $k_0kabdd_0k_0$, which encloses the region where the discharge current and the plasma flow interact with the external magnetic field.

To calculate the volume integral of the axial component of the electromagnetic force it is necessary to know the dependence of the quantity b_r/b_x on the variables x and r; this quantity characterizes the slope of the magnetic lines of force relative to the channel axis. We assume the magnetic field induced by the Hall currents is small in comparison with the external field. Then the ratio b_r/b_x for the external magnetic field can be determined by expanding b_r and b_x in powers of r with respect to the induction of the magnetic field on the axis $b_0(x)$. For a typical channel radius $R_s \ll R_c$ (R_c is the internal radius of the solenoid), the expansions of b_r and b_x can be limited to the first term, so that

$$\frac{b_r}{b_x}=-\frac{r}{2R_s}\frac{d\ln b_0^0}{dx^0}=\frac{r}{2R_s}\varkappa. \tag{2.10}$$

Here, $b_0^0 = b_0(x)/b_s$, $x^0 = x/R_s$, where b_s is a typical value of the external magnetic field induction in the channel (for example, at the cathode) and $b_0(x)$ is the magnetic induction on the channel axis.

Calculated dependences on $z^0 = z/a_1$ for the quantities b_0^0 and $\varkappa$ are shown in Fig. 2 for several versions of solenoids with the constant current density ordinarily used in accelerator testing. It is clear from Fig. 2 that the quantity $\varkappa$ first rises rapidly from 0 to its maximum value and then either remains constant or decreases slowly as z^0 increases. We substitute b_r/b_x from Eq. (2.10) into Eq. (2.2) for $(\mathbf{j} \times \mathbf{b})_x$ and take the quantity $\beta_x\varkappa$ outside the integral sign in $\int_V j_\theta b_r dV$ using the theorem of the mean. This can be done if β_x does not change markedly in the volume of the accelerator channel. By analogy with what has been done before, we obtain

$$\int_V j_\theta b_r dA\,dx=\frac{\pi\beta_x(\alpha)\varkappa}{R_s}\oint\left(\frac{e\alpha}{m_i}\Psi+J\right)d\Phi. \tag{2.11}$$

We compute the contour integrals in Eqs. (2.8), (2.9), and (2.11). Let the distribution of j_x, g_x, and b_x be uniform in the initial section, i.e., at the cathode. To simplify the calculations, we assume that the distributions of b_x and g_x are uniform in the section dd. In addition, we assume that the short-circuit region at the anode is small, i.e., the points a and b of the contour $k_0kabdd_0k_0$ are close to each other. This last condition makes it possible to disregard the drop in discharge current along the axial coordinate in the anode short-circuit region in calculating a contour integral. The contour integral $\oint[(e\alpha/m_i)\Psi + J)]d\Phi$ over the contour $k_0kabdd_0k_0$ can be written

$$\oint\left(\frac{e\alpha}{m_i}\Psi+J\right)d\Phi=\int_k^a\left(\frac{e\alpha}{m_i}\Psi+J\right)d\Phi+\int_b^d\left(\frac{e\alpha}{m_i}\Psi+J\right)d\Phi$$
$$-\int_{d_0}^d\left(\frac{e\alpha}{m_i}\Psi+J\right)\frac{\partial\Phi}{\partial r}dr+\int_{k_0}^k\left(\frac{e\alpha}{m_i}\Psi+J\right)\frac{\partial\Phi}{\partial r}dr. \tag{2.12}$$

Here, the sections kk and dd are assumed to be plane so that $d\Phi = (\partial\Phi/\partial r)dr$, and the integrals along the segments ab and d_0k_0 are zero because $d\Phi = 0$. Because the quantities Ψ and J remain constant on the segments ka and bd of the contour, with J = 0 on the segment bd, the first and second integrals in (2.12) will be

$$\int_k^a\left(\frac{e\alpha}{m_i}\Psi+J\right)d\Phi=\left(\frac{e\alpha}{m_i}\Psi_0+J_0\right)(\Phi_a-\Phi_k), \tag{2.13}$$

$$\int_b^d\left(\frac{e\alpha}{m_i}\Psi+J\right)d\Phi=\frac{e\alpha}{m_i}\Psi_0(\Phi_d-\Phi_a). \tag{2.14}$$

Here, $\Psi_0 = \int_0^R g_x r dr = G/2\pi$, $J_0 = \int_0^R j_x r dr = J_p/2\pi$, R is the boundary of the plasma jet or of the channel, $\Phi_a = \int_0^{R_a} b_x r dr$, $\Phi_k = \int_0^{R_k} b_x r dr$, $\Phi_d = \int_0^{R_d} b_x r dr$ are the magnetic field fluxes through the area of a section of the channel or of the plasma jet at the corresponding points a, k, and d on the contour. By definition, $\partial\Phi/(\partial r) = b_x r$, $\Psi = \int_0^r g_x r dr$, $\Phi = \int_0^r b_x r dr$. Then the third and fourth integrals for uniform radial distribution of g_x, j_x, and b_x and for the boundary condition $\mathbf{j}\cdot\mathbf{n} = 0$ on dd will be

$$\int_{d_0}^d\left(\frac{e\alpha}{m_i}\Psi+J\right)\frac{\partial\Phi}{\partial r}dr=\frac{e\alpha}{m_i}\Psi_0\frac{\Phi_d}{2}, \tag{2.15}$$

$$\int_{k_0}^k\left(\frac{e\alpha}{m_i}\Psi+J\right)\frac{\partial\Phi}{\partial r}dr=\left(\frac{e\alpha}{m_i}\Psi_0+J_0\right)\frac{\Phi_k}{2}. \tag{2.16}$$

In the distributions of g_x and b_x in the section dd of the plasma jet, the value of the integral on the left side of Eq. (2.15) will differ from Eq. (2.15) only by a factor of order unity. For example, in the case of a jet profile $g_x = g_0[1 - (r/R)^{3/2}]$ (g_0 is the value of the mass flow on the axis), the factor is 1.36.

Summing the calculated integrals in Eq. (2.12), after simple transformations we obtain

$$\oint\left(\frac{e\alpha}{m_i}\Psi+J\right)d\Phi=J_0\Phi_k\left(1+\frac{\alpha}{\xi}\right)\left\{\frac{\Phi_a}{\Phi_k}\left[1+\frac{\alpha}{\alpha+\xi}\left(\frac{c}{2}\frac{\Phi_d}{\Phi_a}-1\right)\right]-\frac{1}{2}\right\}. \tag{2.17}$$

Here, c is a factor of order unity, which takes account of the nonuniform distribition of g_x in the section dd, and $\xi = m_i J0/e\psi_0$ is an exchange parameter. The exchange parameter was first introduced in ref. 10 and characterizes

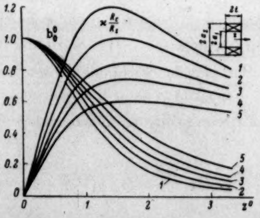

Fig. 2. Axial distribution of the quantity $b_0^0(x)$ and of the parameter $\varkappa$ for solenoids with constant current density. δ: 1) 1.4; 2) 1.9; 3) 2.5; 4) 3.0; 5) 4.0. γ = 0.6, $\delta = a_2/a_1$, $\gamma = t/a_1$, $z^0 = z/a_1$.

the ratio between the Hall electric field and the induction electric field **v** × **b**.

It should be noted that the limitations under which the contour integral (2.12) is calculated are not fundamental; for a given cathode shape, given distributions of g_x, j_x, and b_x at the beginning of the channel, known distributions of g_x and b_x in section dd of the plasma jet, and a known reduction of discharge current in the segment *ab* of the contour, the integrals on the right side of Eq. (2.12) can be calculated easily.

The axial force accelerating the plasma and acting on the solenoid can be written with the use of Eq. (2.17):

$$\int\limits_V j_\theta b_r dA\,dx = \frac{\langle \beta_x(a)\rangle \varkappa}{2R_s} J_d \Phi_k \left(1+\frac{a}{\xi}\right)\left\{\frac{\Phi_a}{\Phi_k}\left[1+\frac{a}{a+\xi}\left(\frac{c}{2}\frac{\Phi_d}{\Phi_a}-1\right)\right]-\frac{1}{2}\right\}. \tag{2.18}$$

The angular momentum relative to the x axis, or the torque which acts to twist the plasma, can be found from Eq. (2.9):

$$\int\limits_V (j_r b_x - j_x b_r)\, r\, dA\,dx = J_d \Phi_k \left(\frac{\Phi_a}{\Phi_k}-\frac{1}{2}\right). \tag{2.19}$$

Consequently, the angular velocity of the plasma in the section dd will be given by

$$\omega_d = \frac{2J_d \Phi_k \left(\frac{\Phi_a}{\Phi_k}-\frac{1}{2}\right)}{G R_d^2}.$$

Note that for $\Phi_k = b_k(R_k^2/2)$, the angular velocity of the plasma is proportional to the parameter $J_d b_k/G$. This dependence has been observed experimentally.[11]

To compute the integral determining the plasma pressure force on the cathode in Eq. (1.10) we use the representation of $j_\theta b_x$ in the form (2.7). We then have

$$\int\limits_A j_\theta b_x r\, dA = 2\pi \langle \beta_x(a)\rangle \left\{ \int\limits_0^R \frac{\partial}{\partial x}\left[\left(\frac{ea}{m_i}\Psi + J\right)\frac{\partial \Phi}{\partial r}\right] dr - \int\limits_0^R \frac{\partial}{\partial r}\left[\left(\frac{ea}{m_i}\Psi + J\right)\frac{\partial \Phi}{\partial x}\right] dr \right\}. \tag{2.20}$$

With the help of the rule for differentiation of an integral with respect to a parameter, we obtain

$$\int\limits_A j_\theta b_x r\, dA = 2\pi \langle \beta_x\rangle \left\{ \frac{d}{dx}\int\limits_0^R \left(\frac{ea}{m_i}\Psi + J\right)\frac{\partial \Phi}{\partial r}\, dr - 2\left(\frac{ea}{m_i}\Psi_0 + J_0\right)\left[\frac{d\Phi(r=R)}{dx}\right]_{x=0} \right\}.$$
